The aorta is transected, and the aortic valve is removed. The annulus is sized, and the appropriate valved conduit, stentless root, mechanical composite, or homograft is brought to the field. The coronary ostia are mobilized. Annular sutures are placed and are passed through the valve conduit. The proximal suture is thus secured. The coronary ostia are reimplanted. The distal suture line is performed for the mechanical valve composite, but an additional Dacron graft extension may be required for the stentless roots or homografts, depending on their length.

Modified Bentall procedure ("buttons"): The right and left coronary arteries are dissected as a button, which is then reimplanted into the Dacron composite graft as an aortic button.

Cabrol procedure: Rarely performed, this technique may be used when the aortic tear or dissection extends into the coronary ostia. It may also be used when adequate mobilization of the coronary ostia is not possible (i.e., from scarring in a reoperation), or when the coronary ostia are too low. The coronary buttons are dissected and anastomosed to a separate 6- or 8-mm Dacron interposition graft; this graft is then anastomosed into the Dacron composite graft. This technique results in a tension-free anastomosis of the coronary buttons and also allows for easier access for hemostasis. However, it is subject to twisting and kinking with resultant myocardial ischemia and, thus, is not as reproducible as the modified Bentall.

Open distal anastomosis

Deep hypothermic circulatory arrest with or without antegrade or retrograde cerebral perfusion is used. When cooled to 18°C (64.4°F), the pump is turned off and the arterial line is clamped. The patient is placed in the Trendelenburg position, and the aortic cross clamp is removed. The distal anastomosis is performed open with running 4-0 Prolene and a strip of felt. The distal anastomosis may be at the level of the innominate artery or, in the case of hemiarch replacement, along the undersurface of the arch to the level of the left subclavian artery. Once the anastomosis has been completed, the pump is restarted with blood flow antegrade into the new graft and open proximal tube graft to flush out air and debris. The graft is then clamped; the proximal aortic reconstruction is performed during rewarming.

Hypothermia decreases oxygen consumption. For each drop in temperature by 1°C, the oxygen consumption by the tissues is reduced by 10%.

Air (ie, nitrogen) is poorly soluble in blood. The risk of air embolism is reduced by flooding the surgical field with carbon dioxide. Carbon dioxide is denser than air and displaces air. It is rapidly soluble in blood and causes less risk of embolization. Any carbon dioxide absorbed in the blood is removed by increasing the sweep speed of cardiopulmonary bypass.

Aortic arch aneurysm repairs

Cannulation for arch repairs varies among groups. They include the femoral artery, right axillary artery, and ascending aorta. Hypothermic circulatory arrest is required for arch repairs, but the safe period of arrest to avoid neurologic injury is 30-45 minutes at 18°C (64.4°F), but some advocate a shorter period of 25 minutes. Antegrade cerebral perfusion to minimize neurologic injury is thus advocated. Others advocate cooling to 11-14°C (51.8-57.2°F).

Once the patient is cooled to the desired temperature, the circuit is turned off. For retrograde cerebral perfusion, flow is established through the superior vena cava as the arch reconstruction is performed. For antegrade cerebral perfusion, flow is continued through the axillary artery with the innominate artery clamped or individual perfusion catheters are placed into the innominate artery, left carotid artery, and left subclavian arteries. The arch reconstructions are also varied. They basically involve performing the distal anastomosis to the aorta beyond the left subclavian artery as an open distal procedure with or without an elephant trunk. The 3 head vessels may be reanastomosed individually or as an island. They may be reimplanted directly to the graft or anastomosed to a separate graft, which is then attached to arch graft.

Descending thoracic aneurysm and thoracoabdominal aneurysm repairs

Measures to reduce spinal cord injury include cerebrospinal fluid drainage, reimplantation of intercostal arteries, partial bypass, and mild hypothermia. A left thoracotomy or a thoracoabdominal incision is performed. The aorta is cross-clamped either just beyond the left subclavian or between the left carotid and left subclavian for Crawford types I and II. The cross clamp is placed more distally for Crawford types III and IV.

Atrial femoral bypass is established with a Bio-Medicus circuit, and the patient is cooled to 32-34°C (89.6-93.2°F). Distal cross-clamping is performed at T4-T7 to allow continued spinal cord, visceral, and renal perfusion. The proximal anastomosis is performed with running 4-0 Prolene and a strip of felt. When complete, the proximal clamp is released and reapplied more distally on the tube graft. The distal cross clamp is moved sequentially down, if feasible, to allow visceral and renal perfusion. The intercostal arteries may be reimplemented, if desired, or oversewn. If sequential cross-clamping is not feasible, direct catheters may be placed in the visceral and renal vessels to allow continuous perfusion.

If the distal aneurysm extends to the renals, then the distal anastomosis may be beveled to incorporate the visceral and renal vessels and distal aorta. If the distal aneurysm extends to the bifurcation, the visceral and renal vessels are reattached to the tube graft. The left renal artery typically requires a separate anastomosis, but the celiac, superior mesenteric, and right renal arteries are often incorporated as a single island. The patient is rewarmed, and the partial bypass is discontinued as the tube graft perfuses the intercostals and abdominal vessels. The distal anastomosis at the bifurcation is performed as an open distal procedure.

For appropriate descending thoracic aortic aneurysms, endovascular stent grafting is a good alternative. Depending on the size of the patient's femoral or iliac arteries and size of the stent graft required, femoral or iliac artery exposure is performed under general or local anesthesia plus sedation. A sheath is placed and a wire guided under fluoroscopy into the arch. When in proper position, the floppy wire is exchanged with a soft catheter and rewired to a stiffer wire for device placement. The sheath is exchanged for the appropriate device sheath. The contralateral groin is used for angiocatheter placement.

After angiography and determination of stent placement, the device is loaded and, under fluoroscopic guidance, is positioned and deployed. More than one stent may be used, with as much overlap as is feasible, for stability. The proximal and distal landing zones are ballooned to seal the endograft to the aorta. The overlapping stent-graft segments are also ballooned. Angiography is performed to check for endoleaks. Endoleaks may require additional stents.

Ross procedure (pulmonary autograft)

The aortic root and proximal ascending aorta are replaced with a pulmonary autograft.²³ The pulmonary valve is then replaced with a pulmonary homograft. Most commonly performed in children with congenital disease, the Ross operation may be used for active young adults with aneurysmal disease (excluding those with connective tissue disorders), women of childbearing age who desire pregnancy, or patients with contraindications to anticoagulation.

Postoperative Details

Patients who have undergone ascending aneurysm repairs are observed for signs of coronary ischemia, particularly if the coronary ostia were reimplanted, and for signs of aortic insufficiency when the aortic valve is repaired. Following the repair of arch aneurysms, particular attention must be given to neurological status, and patients who have had the elephant trunk repair must be observed for signs of paraplegia because the telescoped sleeve in the descending aorta may obstruct critical spinal vessels.

Paraplegia is the main concern in patients who have had repair of the descending and thoracoabdominal aorta. Cerebrospinal fluid drainage may be continued for up to 72 hours postoperatively if necessary, along with motor evoked potential monitoring. Paraplegia and paraparesis may be acute or delayed postoperatively. If paraparesis or paraplegia is delayed, increased mean arterial pressure with pressors and reinstatement of cerebrospinal fluid drainage may augment spinal cord perfusion to reverse this complication. Paraplegia due to occlusion of critical spinal arteries that were not reimplanted cannot be reversed by these maneuvers. Acute postoperative renal dysfunction may be due to extended periods of ischemic cross-clamping or to hypothermic circulatory arrest.

Patients undergoing endovascular stenting are often extubated early postoperatively with a decreased ICU length of stay.

Complications

Early morbidity and mortality are related to bleeding, neurologic injury (eg, stroke), cardiac failure, and pulmonary failure (eg, acute respiratory distress syndrome [ARDS]). Risk factors include emergent operation, older age, dissection, congestive heart failure (CHF), prolonged cardiopulmonary bypass time, arch replacement, previous cardiac surgery, need for

concomitant coronary revascularization, and reoperation for bleeding. Late mortality is usually related to cardiac disease or distal aortic disease.

Bleeding is a potential complication for all aneurysm repairs. It is minimized by the use of antifibrinolytics, felt strips, and factors, including fresh frozen plasma and platelets. For patients who undergo hypothermic circulatory arrest, the use of aprotinin is controversial, but most groups routinely use aminocaproic acid (Amicar). Coagulopathy and bleeding in severe cases may warrant the use of recombinant factor VII.

Aprotinin (Trasylol), an antifibrinolytic agent used to reduce operative blood loss in patients undergoing open heart surgery, is now only available via a limited-access protocol. Fergusson et al reported an increased risk for death compared with tranexamic acid or aminocaproic acid in high-risk cardiac surgery.³¹

Stroke is a major cause of morbidity and mortality and typically results from embolization of atherosclerotic debris or clot. Transesophageal echocardiography and epiaortic ultrasound may be beneficial in localizing appropriate areas to clamp. Patients undergoing arch repairs are at the highest risk of permanent and transient neurologic injury. Retrograde cerebral perfusion is beneficial for flushing out embolic debris, but it may be detrimental, with increased intracranial pressure and cerebral edema. Antegrade cerebral perfusion is beneficial for reducing neurologic injury during hypothermic circulatory arrest. Stroke incidence for open surgical repair versus endovascular repair of descending thoracic aneurysms is equivalent.

Myocardial infarction may occur with technical problems with coronary ostia implantation during root replacement for ascending aortic aneurysms and may require reoperation. Pulmonary dysfunction and renal dysfunction are other potentially morbid complications.

Paraparesis and paraplegia, either acute or delayed, are the most devastating complications of descending thoracic aneurysm and thoracoabdominal aneurysm repairs. Despite cerebrospinal drainage, reimplantation of intercostal arteries, evoked potential monitoring, mild hypothermia, and atrial femoral bypass, spinal cord injury still occurs. Endovascular stent grafting has not eliminated spinal cord paraplegia; the incidence varies widely, with an overall incidence of 2.7%.^{24,25,27,28}

Complications specific to endovascular stenting include endoleaks, stent fractures, stent graft migration or thrombosis, iliac artery rupture, retrograde dissection, microembolization, aorto-esophageal fistula, and complications at the site of delivery (eg, groin infection, lymphocele, seroma).

TOPIC 20. DISEASES OF THE VEINS. SYNDROME OF SUPERIOR VENA CAVA. SYNDROME OF INFERIOR VENA CAVA. CAUSES, DIAGNOSTIC, DIFFERENTIAL DIAGNOSTIC, TREATMENT TACTIC.

VARICOSE VEINS

Epidemiology of Chronic Peripheral Venous Disease

The term chronic venous disease, or more specifically of interest here, chronic peripheral venous disease (CPVD) has been used more generally to refer to either visible and/or functional abnormalities in the peripheral venous system. The most widely used classification of such abnormalities is the CEAP (Clinical, Etiological, Anatomic, Pathophysiologic), which includes both anatomic (superficial, deep, or perforating veins) and pathophysiologic (reflux, obstruction, both) categories.

The CEAP classification was created by an international committee of clinical experts, and reflects the clinical situation in patients typically referred to a vascular specialist for clinically significant venous disease. In contrast to the clinical situation, population studies of CPVD typically have focused on broader categories determined by visual inspection only. The three major categories of interest have been varicose veins (VV), chronic venous insufficiency (CVI), and venous ulcers. However, there has not been a standard definition of these categories. VV has been defined both including and excluding telangiectasias (spider veins), and at differing levels of visible disease severity. CVI typically has been defined by skin changes and/or edema in the distal leg. Venous ulcers, both active and healed, have been defined by visual inspection and subjective inference as to etiologic origin.

Two studies have now reported results on defined free-living populations with simultaneous assessment of both visible abnormalities and functional impairment by Duplex ultrasound.

The Duplex examination for the San Diego Population Study (SDPS) determined both obstruction and reflux, whereas the Edinburgh study determined only the latter. These studies have raised some questions regarding the validity of the assumptions based on earlier population studies and regarding the utility of the CEAP classification, at least as applied to largely healthy population samples. Specifically, the general concept that visible disease necessarily implied underlying functional disease, and vice versa, was true in the large majority of affected limbs, but not universally so.

Although these discrepancies occurred in a minority of cases, they were frequent enough to lead us to separately classify visible and functional CPVD in each limb evaluated in the SDPS. Specially, we classified each limb into four visible categories: normal, telangiectasias/spider veins (TSV), VV, and trophic changes (TCS), the latter category being one or more of hyperpigmentation, lipodermatosclerosis, or active or healed ulcer. The presence/absence of edema was not by itself a criterion for TCS. For functional disease, we determined the presence of obstruction and reflux separately for the superficial, perforating, and deep systems. The presence of either reflux or obstruction in superficial or deep veins was categorized as functional disease, and because of small numbers, abnormalities of the perforating veins were considered as deep disease. Three functional categories were defined: normal, superficial functional disease (SFD), and deep functional disease (DFD). Here, the term “functional” is essentially interchangeable with “anatomic.” Also, in this population study obstruction was uncommon, and virtually all legs with obstruction also had reflux, such that SFD and DFD essentially refer to reflux.

In addition to separately assessing edema, we asked about a history of superficial venous thrombosis (SVT) and deep venous thrombosis (DVT), with or without pulmonary embolism.

AGE AND CVPD

Using mutually exclusive categories for both visible and functional CVPD, we found a graded relationship with increasing age for VV, with those aged 70–79 years having nearly twice the prevalence of those aged 40–49 years. TSV also increased with age, but this difference was obscured by the mutually exclusive categories with increasing numbers of participants with TSV also having VV or TCS at older ages. TCS showed the most dramatic age-related increase, with the oldest age group having more than four times the prevalence of the youngest.

These findings for visible disease are consistent with most previous population studies, which generally have found a linear increase in TSV or VV with age (reviewed in Reference 4). Earlier studies typically defined CVI only by venous (assumed) ulcers, and reported exponential increases in CVI with age, findings similar to the dramatic age increase we reported for the broader TCS category.

For functional CVPD, SFD was more than twice as common and DFD was 64% more common in the oldest age group. SFD showed both a higher prevalence and a steeper age gradient than did DFD.

The only other population data on functional disease were from the Edinburgh study and were limited to reflux, and showed similar gradients with age.

Edema was strongly age-related as expected, but history of SVT and DVT were somewhat less so, perhaps reflecting selective recall bias in older participants.

Nonetheless, our data for DVT overall are quite similar to the lifetime prevalence in a large population-based study.

GENDER AND CPVD

For visible disease, we found nearly twice as much VV in women as in men, but TCS were 50% more common in men. These findings for VV are consistent with earlier studies, but earlier studies also have suggested a small excess of CVI in women, in contrast to our findings for the broader category of TCS. However, more concordant with our findings, the Edinburgh study reported that CVI was twice as common in men as women. For functional CPVD, only the Edinburgh study has comparable data, and only for reflux, and found a gender ratio for functional disease similar to the SDPS.

Edema was about 50% more common in men than women, consistent with a 50% greater history of DVT in men. The Edinburgh group reported more edema in women, but a discordance with CVI being more common in men.

ETHNICITY AND CPVD

The SDPS reported data for four ethnicities, nonHispanic White, Hispanic, African-American, and Asian. Non-Hispanic Whites showed the highest prevalence of CPVD, with only 14.3% with a normal examination. Non-Hispanic Whites had the highest rates of TSV, TCS, and DFD, and the second highest rates (after Hispanics) of VV and SFD. African-Americans and Asians had a somewhat lower prevalence of CPVD. Consistent with the visible and functional findings, Non-Hispanic Whites also had the highest rates of edema and DVT by history, and Hispanics the highest rate of SVT by history.

Several previous studies have suggested a higher prevalence in developed than developing countries, although these studies are not entirely consistent. The SDPS is the first population study to evaluate multiple ethnic groups who were residents of the same geographical area.

RISK FACTORS FOR CPVD

Age was positively consistently related to all levels of visible and functional disease in both sexes. In comparison with non Hispanic whites (NHW), African-American Asian had less TSV and VV in both sexes, less TCS in men, and less DFD in women. Our results thus confirm that older age and NHW ethnicity are risk factors for CPVD.

Family history of venous disease based on subject recall was a risk factor for all levels of visible and functional disease. Although this finding could be biased, it is consistent with many other studies, although not all.

Ankle motility was a risk factor for visible disease SFD in women and for TSV in men. It was protective for women with DFD and men with SFD. The association of increasing laxity in connective tissue with venous disease corroborated previous research.

The protective associations could reflect increased ankle motility leading to decreased venous pressure by increasing pumping action.

Lower limb injury was a risk factor in women for DFD. Coughlin et al., in a case-control study, found serious lower limb trauma to be a risk factor for CVI.

CVD-related factors, such as angina, PTCA, hypertension, and diastolic pressure were associated with less TSV, SFD, and DFD for men and women and less VV for men. Although some studies have found a relationship between atherosclerosis and venous disease, others have not.

The reason for any protective effect of cardiovascular disease and hypertension on CPVD is not readily apparent, although venous vasoconstriction and microthrombosis could conceivably be involved.

Hours spent walking or standing was positively associated with VV, TCS, and SFD in men and women. Fowkes et al. found that walking was a risk factor for women with venous insufficiency when age-adjusted, but less so when multiply adjusted. They found walking to be related to lessened risk of venous insufficiency in men. Our data indicate that standing was a strong risk factor for venous disease in women. This is concordant with a number of studies, and contrasts with some other studies.

Weight, height, waist, and BMI, defined as weight in kg divided by height squared in meters squared, were positively associated with TCS, and DFD in men and VV, TCS, and SFD in women. Weight, waist circumference, the waist/hip ratio, and body mass index are all measures of adiposity.

A number of studies have found an association of obesity with venous disease. Gourgou

et al. found a relationship in both men and women with VV. Our finding of increased waist circumference in men with TCS was consistent with findings that both obesity and male gender were associated with CVI and with the finding that weight was an independent risk factor for CVI in multivariate analysis. In contrast, Coughlin et al. and Fowkes et al. both found that obesity was not a factor in venous insufficiency among women. Fowkes et al. extended this finding to men as well. Other studies also have found no association between obesity and venous disease.

However, the Edinburgh group also found that for men and women combined, persons with greater severity of varices (i.e., more segments with reflux) had higher body mass indices than those with fewer segments involved. Additionally, Fowkes et al. found that varicosities in the superficial system, but not in the deep system, were related to body mass index in women. Exercise was associated with lower rates of TSV, TCS, and SFD in men. This is concordant with the finding of Gourgou et al. that physical activity is related to less VV.

During exercise the venomuscular pump is activated, which leads to a transient decrease in venous pressure, which should be protective for venous disease. This is consistent with our results in men.

HRT duration or parity was positively associated with all levels of visible and functional disease in women. Gourgou et al. found increasing VV prevalence with increasing numbers of births. Coughlin et al. found that multiparity was associated with varicose veins in pregnant women.

Some studies have found that the changes are effected with only one pregnancy. The increase of CPVD with HRT duration may indicate yet another underexamined systemic effect of HRT.

Our data indicate that age and family history were the strongest risk factors for CPVD, and neither is subject to intervention. Other significant findings on inherent factors included associations with connective tissue laxity and height. CVD-related factors were associated with lower rates of venous disease. Among volitional factors important findings were a relationship of CPVD with central adiposity, positional factors such as hours spent standing or sitting, exercise, and selected hormonal factors in women. In contrast with prior studies, we found no relationship with dietary fiber intake. In women but not men we confirmed the importance of a previous lower limb injury for DFD.

VENOUS ANATOMY, PHYSIOLOGY, AND PATHOPHYSIOLOGY

ANATOMY

The venous system in the lower extremities can be divided, for purposes of understanding, into three systems: the deep system, which parallels the tibia and femur; the superficial venous system, which resides in the superficial tissue compartment between the deep muscular fascia and the skin; and the perforating or connecting veins, which join the superficial to the deep systems. It is because these latter veins penetrate anatomic barriers, they are called perforating veins.

Although the superficial veins are the targets of most therapy, the principal return of blood flow from the lower extremities is through the deep veins. In the calf, these deep veins are paired and named for their accompanying arteries.

Therefore, the anterior tibial, posterior tibial, and peroneal arteries are accompanied by their paired veins, which are interconnected. These crural veins join and form the popliteal vein. Occasionally the popliteal veins as well as more proximal deep veins are also paired like the calf veins.

As the popliteal vein ascends, it becomes the femoral vein. Formerly, this was called the superficial femoral vein, but that term has been abandoned. Near the groin the femoral vein is joined by the deep femoral vein, and the two become the common femoral vein, which ascends to become the external iliac vein proximal to the inguinal ligament.

Ultrasound imaging has shown that the superficial compartment of the lower extremities consists of two compartments, one enclosing all the structures between the muscular fascia and the skin, and the other, within the superficial compartment enclosing the saphenous vein and bounded by the muscular fascia inferiorly and the superficial fascia superiorly, is termed the saphenous compartment (see Figure 1). The importance of this anatomic structure is underscored by its being targeted during percutaneous placement of endovenous catheters and the instillation of tumescent anesthesia.

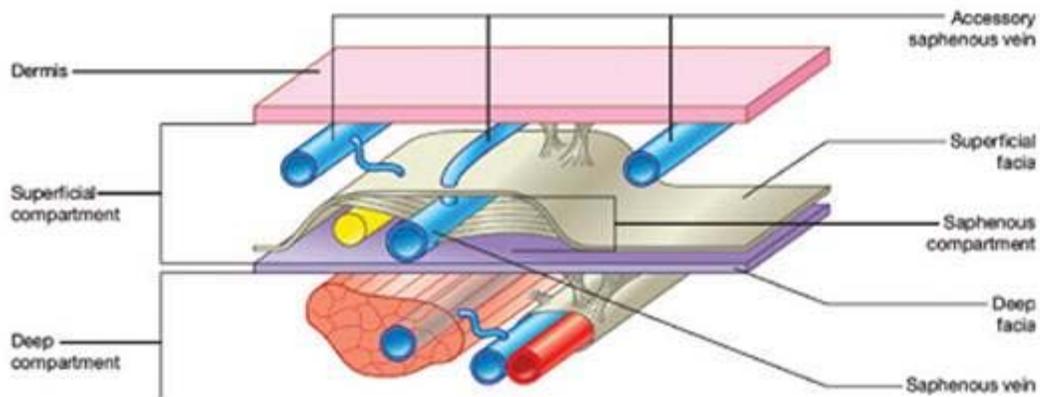

Fig. 1 This diagram of the Saphenous Compartment shows its relationships with the Superficial and Deep compartments as well as the Saphenous Vein (SV) and Nerve and their relationships to the Medial, Anterior, and Lateral Accessory Saphenous Veins (ASV).

The main superficial veins are the great saphenous vein and the small saphenous vein. These receive many interconnecting tributaries, and these tributaries may be referred to as communicating veins. They are correctly called tributaries rather than branches of the main superficial veins. The great saphenous vein has its origin on the dorsum of the foot.

It ascends anterior to the medial malleolus of the ankle and further on the anteromedial aspect of the tibia. At the knee, the great saphenous vein is found in the medial aspect of the popliteal space. It then ascends through the anteromedial thigh to join the common femoral vein, just below the inguinal ligament. Throughout its course, it lies within the saphenous compartment. The small saphenous vein originates laterally from the dorsal venous arch of the foot and travels subcutaneously behind the lateral malleolus at the ankle. As it ascends in the calf, it enters the deep fascia and ascends between the heads of the gastrocnemius muscle to join the popliteal vein behind the knee (see Figure 2). In fact, there are many variations of the small saphenous vein as it connects both to the popliteal vein and to cranial extensions of the saphenous vein, as well as connections to the posteromedial circumflex vein (vein of Giacomini).

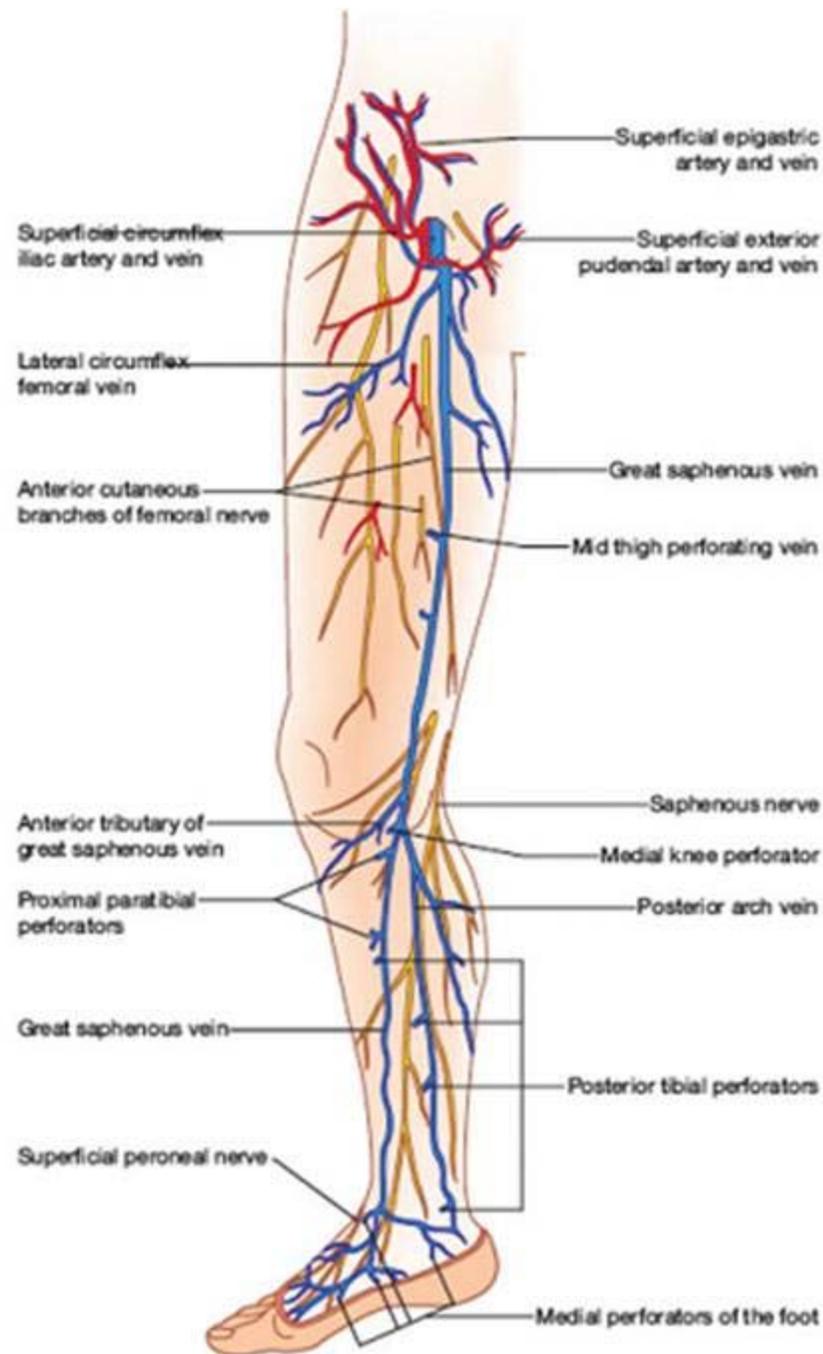

Fig.2. This diagrammatic representation of the Great Saphenous Vein emphasizes its relationship to perforating veins and the Posterior Arch Vein.

The third system of veins is called the perforating vein system. As indicated earlier, they connect the superficial and deep systems of veins. There is a fundamental fact, which confuses understanding of perforating veins. This relates to flow direction. Some perforating veins produce normal flow from the superficial to the deep circulation, others conduct abnormal

outflow from the deep circulation to the superficial circulation. This is termed perforating vein reflux. Any of these perforating veins may demonstrate bidirectional flow (see Table 1).

Table 1. Summary of Important Changes in Nomenclature of Lower Extremity Veins

Old terminology	New terminology
Femoral Vein	Common Femoral Vein
Superficial Femoral Vein	Femoral Vein
Sural Veins	Sural Veins
	Soleal Veins
	Gastrocnemius Veins (Medial and Lateral)
Hungarian Perforator	Mid Thigh Perforator
Cockett's Perforators	Paratibial Perforator
	Posterior Tibial Perforators
May's Perforator	
Gastrocnemius Point	Intergemellar Perforator

In the leg, the principal clinically important perforating veins are on the medial aspect of the ankle and leg, and are found anatomically at approximately 6 cm intervals from the base of the heel through the upper portion of the leg. They are therefore at roughly 6, 12, 18, and 24 cm from the floor (see Figure 3). These medial perforating veins may become targets for treatment of severe chronic venous insufficiency. Smaller perforating veins can be found along intermuscular septa and these allow direct drainage of blood from surface veins into the deep venous system.

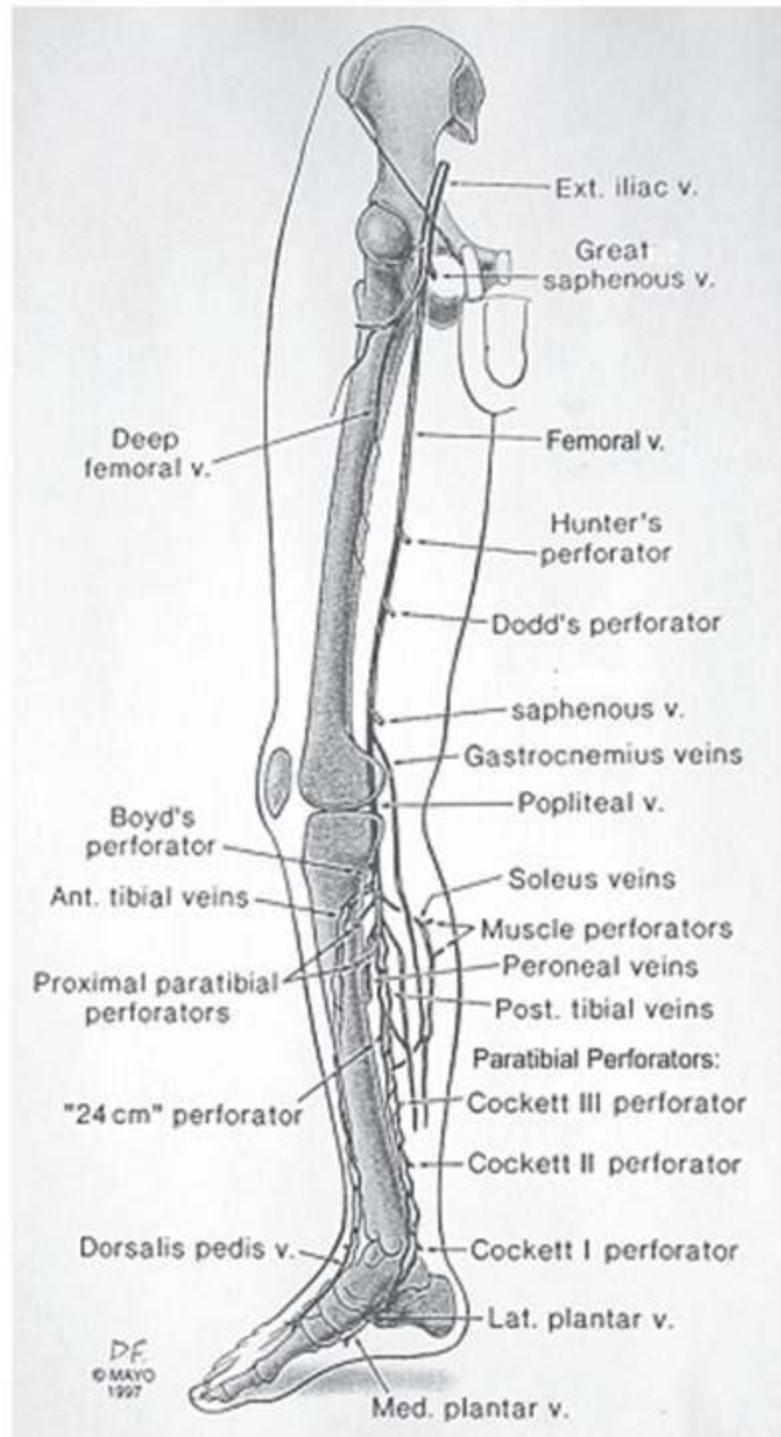

Fig.3. Deep connections of the main thigh and leg perforating veins are shown in this diagram of the deep veins of the lower extremity.

Conversely, when they are dysfunctional, they allow muscular compartment pressure to be transmitted directly to unsupported cutaneous and subcutaneous veins and venules.

VENOUS PHYSIOLOGY

It is estimated that 60 to 75% of the blood in the body is to be found in the veins. Of this total volume, about 80% is contained in the veins that are less than 200 μm in diameter. It is important to understand this reservoir function as it is related to the major components. The splanchnic venous circulation and the veins of the skin are richly supplied by the sympathetic nervous system fibers, but muscular veins have little or none of these. The veins in skeletal muscle, on the other hand, are responsive to catecholamines.

Although arterial pressures are generated by muscular contractions of the heart, pressures in the venous system largely are determined by gravity. In the horizontal position, pressures in the veins of the lower extremity are similar to the pressures in the abdomen, chest, and extended arm. However, with the assumption of the upright position, there are dramatic changes in venous pressure. The only point in which the pressure remains constant is the hydrostatic indifferent point just below the diaphragm. All pressures distal to this point are increased due to the weight of the blood column from the right atrium. When assuming the upright position, there is an accumulation of approximately 500 ml of blood in the lower extremities, largely due to reflux through the valveless vena cava and iliac veins. There is some loss of fluid into the tissues, and this is collected by the lymphatic system and returned to the venous system.

Venous valves play an important role in transporting blood from the lower extremities to the heart. In order for valve closure to occur, there must be a reversal of the normal transvalvular pressure gradient. A pressure and generated velocity flow exceeding 30 cm/second leads to valve closure. Direct observation of human venous valves has been made possible by specialized ultrasound techniques.

Venous flow is not in a steady state but is normally pulsatile, and venous valves undergo regular opening and closing cycles. Even when fully opened, the cross-sectional area between the leaflets is 35% smaller than that of the vein distal to the valve. Flow through the valve separates into a proximally directed jet and vortical flow into the sinus pocket proximal to the valve cusp. The vortical flow prevents stasis and ensures that all surfaces of the valve are exposed to shear stress. Valve closure develops when the vortical flow pressure exceeds the proximally directed jet flow.

The role of venous valves in an individual quietly standing is not well understood. Pressures in the superficial and deep veins are essentially the same during quiet standing, but as Arnoldi has found, the pressure in the deep veins is 1 mm higher, which would tend to keep the valves in the perforating veins closed.

Normally functioning perforating vein valves protect the skin and subcutaneous tissues from the effects of muscular contraction pressure. This muscular contraction pressure may exceed 100 to 130 mmHg.

Intuitively, the role of venous valves during muscular exercise is obvious, since their major purpose is to promote antegrade flow from superficial to deep. Volume and pressure changes in veins within the calf occur with muscular activity. In the resting position, with the foot flat on the floor, there is no flow. However, in the heel strike position, the venous plexus under the heel and plantar surface of the foot (Bejar's plexus) is emptied proximally. Blood flows from the foot and ankle into the deep veins of the calf. Then, calf contraction transports this blood into the deep veins of the thigh, and henceforth, blood flow proceeds to the pelvic veins, vena cava, and ultimately to the heart all due to the influence of lower extremity muscular contraction.

PATHOPHYSIOLOGY

Abnormal functioning of the veins of the lower extremities is recognized clinically as venous dysfunction or, more commonly, venous insufficiency. Cutaneous telangiectases and subcutaneous varicose veins usually are grouped together under the title Primary Venous Insufficiency, and limbs with skin changes of hyperpigmentation, edema, and healed or open venous ulceration are termed Chronic Venous Insufficiency (CVI).

Primary Venous Insufficiency

Explanations of venous pathophysiology as published in reviews, texts, and monographs are now for the most part out of date. The new science as we now know it is incorporated in the following summary.

A dysfunctional venous system follows injury to vein walls and venous valves. This injury is largely due to inflammation, an acquired phenomenon. Factors, which are not acquired, also enter into such injury. These include heredity, obesity, female gender, pregnancy, and a standing occupation in women. Vein wall injury allows the vein to elongate and dilate thus producing the visual manifestations of varicose veins. An increase in vein diameter is one cause of valve dysfunction that results in reflux. The effect of persistent reflux through axial veins is a chronic increase in distal venous pressure. This venous pressure increases as one proceeds from the inguinal ligament past the knee to the ankle.

Prolonged venous hypertension initiates a cascade of pathologic events. These manifest themselves clinically as lower extremity edema, pain, itching, skin discoloration, and ulceration.

The earliest signs of venous insufficiency often are elongated and dilated veins in the epidermis and dermis, called telangiectasias. Slightly deeper and under the skin are flat, blue-green veins of the reticular (network) system. These may become dilated and elongated as well (see Figure 4).

And finally, still deeper but still superficial to the superficial fascia are the varicose veins themselves. All of these abnormal veins and venules have one thing in common: they are elongated, tortuous, and have dysfunctional venous valves.

This implies a common cause, which is inflammation.

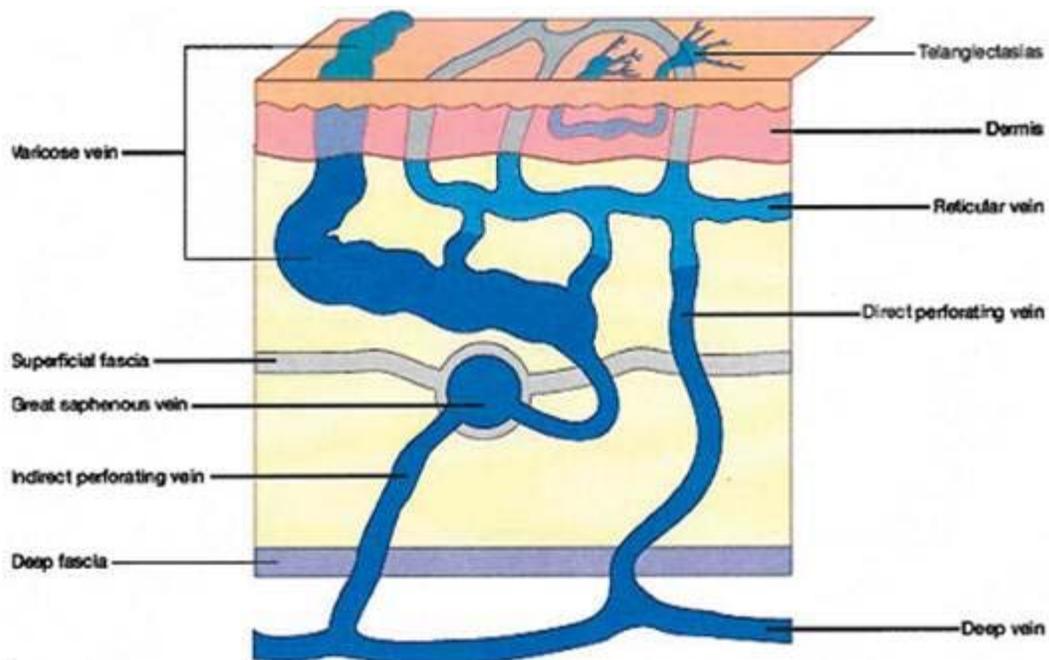

Fig. 4. This cross-sectional view of the subcutaneous venous circulation shows how venous hypertension is transmitted to the unsupported veins of the dermis and subcutaneous tissues from axial veins (GSV) and the deep veins of the muscular compartments.

Chronic Venous Insufficiency

Skin changes of hyperpigmentation, scarring from previous ulceration, and active ulcerations are grouped together under the term chronic venous insufficiency (CVI). Numerous theories have been postulated regarding the cause of chronic venous insufficiency and the cause of venous ulceration.

All the theories proposed in the past century have been disproved. An example is the theory of venous stasis, first proposed in a manuscript by John Homans of Harvard in 1916.

It was a treatise on diagnosis and management of patients with chronic venous insufficiency, and in it, Dr. Homans coined the term “post-phlebotic syndrome” to describe the skin changes of CVI. He stated that, “Over-stretching of the vein walls and destruction of the valves . . . interferes with the nutrition of the skin . . . there-fore, skin which is bathed under pressure with stagnant venous blood will form permanent open sores or ulcers.”

That statement, like many others that describe venous conditions and their treatments, is

steeped in dogma and is short of observational fact. The erroneous term stasis ulcer honors that misconception, as do the terms venous stasis disease and stasis dermatitis.

Alfred Blalock, who later initiated cardiac surgery, disproved the stasis theory by studying oxygen content from varicose veins and normal veins.

He pointed out that the oxygen content of the femoral vein in patients with severe chronic venous insufficiency was greater than the oxygen content of the contralateral nonaffected limb. Because oxygen content was higher, some investigators felt that arteriovenous fistulas caused venous stasis and varicose veins.

That explanation, though disproved, has some basis in fact since the entire thermal regulatory apparatus in limbs depends on the opening and closing of arteriovenous shunts. These shunts are important as they explain some terrible accidents that happen during sclerotherapy when sclerosant entering a vein is shunted into the arterial system and distributed in its normal territory.

Microsphere investigations have failed to show any shunting and the theory of arteriovenous communications has died despite the fact that these shunts actually exist and do open under the influence of venous hypertension.

Hypoxia and its part in causation of chronic venous insufficiency was investigated throughout the last 25 years of the twentieth century. English investigators thought that a fibrin cuff, observed histologically, blocked transport of oxygen and was responsible for skin changes of CVI at the ankles and distally.

That theory has been abandoned even though a true periarteriolar cuff is easily identified histologically.

The two elements that make up all the manifestations of lower extremity venous insufficiency are failure of the vein valves and vein walls and skin changes at the ankles, both of which are related to venous hypertension.

Failure of Vein Walls and Valves

Our work suggests that venous hypertension causes a shear stress dependent leukocyte-endothelial interaction, which has all the manifestations of chronic inflammation.

These are leukocyte rolling, firm adhesion to endothelium, and subsequent migration of the cells through the endothelial barrier into parenchyma of valves and vein walls.

There, macrophages elaborate matrix metalloproteases, which destroy elastin and possibly collagen as well. Vein walls become stretched and elongated. Vein valves become

perforated, torn, and even scarred to the point of near total absence. These changes are seen both macroscopically and angioscopically.

Similar changes have been produced in the experimental animal by constructing an arteriovenous fistula to mimic the venous hypertension of venous dysfunction in humans.

Skin Changes

The second manifestation of chronic venous insufficiency is expressed in the skin where leukocytes also are implicated in the observed changes. There is evidence that leukocyte activation in the skin, perhaps related to venous hypertension, plays a major role in the pathophysiology of CVI. Thomas, working with Dormandy, reported that 25% fewer white cells and platelets left the dependent foot of the patients with venous hypertension. When the foot was elevated there was a significant washout of white cells but not platelets, suggesting platelet consumption within the microcirculation of the dependent foot. They concluded that the decrease in white cell exodus was due to leukocyte trapping in the venous microcirculation secondary to venous hypertension. They further speculated that trapped leukocytes may become activated, resulting in release of toxic metabolites causing damage to the microcirculation and overlying skin. Apparently, the primary injury in the skin is extravasation of macromolecules and red blood cells into the dermal interstitium. Red blood cell degradation products and interstitial protein extravasations are potent chemoattractants and represent the initial chronic inflammatory signal responsible for leukocyte recruitment.

The important observations of Dormandy's group were historically the first to implicate abnormal leukocyte activity in the pathophysiology of CVI.

The importance of leukocytes in the development of dermal skin alterations was further emphasized by Coleridge Smith and his team. They obtained punch biopsies from patients with primary varicose veins, lipodermatosclerosis, and patients with lipodermatosclerosis and healed ulcers. They counted the median number of white blood cells per high power field in each group but there was no attempt to identify the types of leukocytes. In patients with primary varicose veins, lipodermatosclerosis, and healed ulceration there was a median of 6, 45, and 217 WBCs per mm², respectively. This demonstrated a correlation between clinical disease severity and the number of leukocytes in the dermis of patients with CVI.

The types of leukocytes involved in dermal venous stasis skin changes remain controversial. T-lymphocytes, macrophages, and mast cells have been observed on immunohistochemical and electron microscopic examinations.

The variation in types of leukocytes observed may reflect the types of patients investigated. The London group biopsied patients with erythematous and eczematous skin changes, whereas Pappas has evaluated predominantly older patients with dermal fibrosis. Patients with eczematous skin changes may have an autoimmune component to their CVI whereas patients with dermal fibrosis may have experienced pathologic alterations consistent with chronic inflammation and altered tissue remodeling. Skin biopsies have shown that in liposclerotic, eczematous skin macrophages and lymphocytes were predominant in such diseased skin. Infiltration of leukocytes into the extracellular space has been documented by observing the localization of these leukocytes around capillaries and post-capillary venules. Accompanying the leukocytes is a disorganized collagen deposition. Clearly, chronic venous insufficiency of the skin and its subcutaneous tissues is a disease of chronic inflammation, again dependent upon venous hypertension.

SYMPTOMS OF PRIMARY VENOUS INSUFFICIENCY

It is well known that the presence and severity of symptoms do not correlate with the size or severity of the varicose veins present. Symptoms usually attributable to varicose veins include feelings of heaviness, tiredness, aching, burning, throbbing, itching, and cramping in the legs (see Table 2). These symptoms are generally worse with prolonged sitting or standing and are improved with leg elevation or walking. A premenstrual exacerbation of symptoms is also common. Generally, patients find relief with the use of compression in the form of either support hose or an elastic bandage. Weight loss or the commencement of a regular program of lower extremity exercise may also lead to a diminution in the severity of varicose vein symptoms. Clearly, these symptoms are not specific, as they may also be indicative of a variety of rheumatologic or orthopedic problems. However, their relationship to lower extremity movement and compression is usually helpful in establishing a venous origin for the symptoms. Significant symptoms suggestive of venous disease should prompt further evaluation for valvular insufficiency and calf muscle pump dysfunction. If a venous etiology is suspected but all examinations are negative, repeat examination during a symptomatic period is warranted and often fruitful.

The recent development of an extremely painful area on the lower leg at the ankle

associated with an overlying area of erythema and warmth may be indicative of lipodermatosclerosis, which may be associated with insufficiency of an underlying perforator vein, and examination for this lesion should be performed. Lipodermatosclerosis may precede ulceration and has been shown to be improved by stiff compression and certain pharmacologic interventions. Patients with a history of iliofemoral thrombophlebitis who describe “bursting” pain with walking may be suffering from venous claudication. In these patients an evaluation for persistent hemodynamically significant obstruction, possibly treatable with angioplasty and stenting, may be in order.

Table 2. Symptoms of Varicose Veins and
Telangiectasias

Aching Heaviness (on standing, prolonged sitting)
Aching Pain (on standing, prolonged sitting)
Burning (venous neuropathy)
Itching (cutaneous inflammation)
Nocturnal Cramps (recumbent edema reduction)

PHYSICAL EXAMINATION

Using no special equipment, the practitioner can obtain a degree of information regarding overall venous out flow from the leg, the sites of valvular insufficiency, the presence of primary versus secondary varicose veins, and the presence of DVT. The screening physical examination consists of careful observation of the legs. Any patient with the following conditions should be examined more fully: large varicose veins; bulges in the thigh, calf, or the inguinal region representative of incompetent perforating veins (IPVs) or a saphena varix; signs of superficial venous hypertension such as an accumulation of telangiectasias in the ankle region (corona phlebectatica); or any of the findings suggestive of venous dermatitis (pigmentation, induration, eczema). This includes patients with obvious cutaneous signs of venous disease such as venous ulceration, *atrophie blanche*, or lipodermatosclerosis. An obvious but often forgotten point is the necessity of observing the entire leg and not confining the examination simply to the area that the patient feels is abnormal.

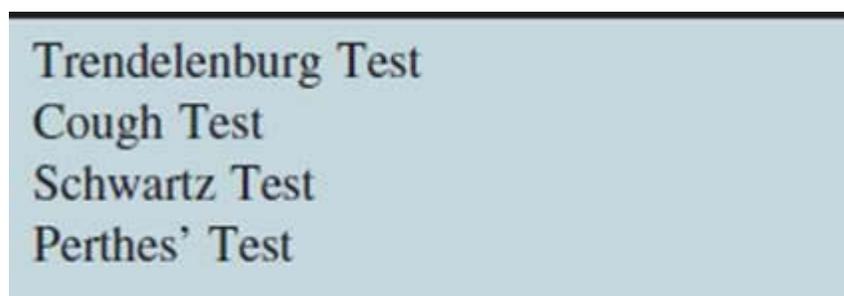

Finally, because the veins of the leg empty into the pelvic and abdominal veins, inspection of the abdomen is very important, since dilation of veins on the abdominal wall or

across the pubic region suggests an old iliofemoral thrombus. Dilated veins along the medial or posterior aspect of the proximal thigh or buttocks most often arise from varicosities involving the pudendal or other pelvic vessels, and these can be of ovarian reflux origin.

CLINICAL TESTING

Historically important tests of venous function have been part of the physical examination of venous insufficiency (see Table 3). These tests have been laid aside largely because of their lack of specificity and sensitivity. The continuouswave Doppler examination has replaced most of these tests, and confirmatory duplex testing has relegated them to an inferior role. However, the educated physician who treats venous insufficiency must have knowledge of these tests and their physiologic background, such as the Trendelenburg test or Brodie-Trendelenburg test.

Table 3. Tests of Historic Interest

Trendelenburg Test
Cough Test
Schwartz Test
Perthes' Test

Trendelenburg Test

A tourniquet may be placed around the patient's proximal thigh while the patient is standing. The patient then assumes the supine position with the affected leg elevated 45 degrees. The tourniquet is removed, and the time required for the leg veins to empty, which is indicative of the adequacy of venous drainage, is recorded. When compared with the contralateral leg, the method just described may demonstrate a degree of venous obstructive disease. Another approach is to elevate the leg while the patient is supine and to observe the height of the heel in relation to the level of the heart that is required for the prominent veins to collapse. Unfortunately, neither procedure is sufficiently sensitive nor accurate and does not differentiate acute from chronic obstruction, thus being of minimal assistance in current

medical practice.

Cough Test

One hand is placed gently over the GSV or SFJ, and the patient is asked to cough or perform a Valsalva maneuver. Simply palpating an impulse over the vein being examined may be indicative of insufficiency of the valve at the SFJ and below to the level of the palpating hand.

Percussion/Schwartz Test

One hand is placed over the SFJ or SPJ, and the other hand is used to tap very lightly on a distal segment of the GSV or SSV. The production of an impulse in this manner implies insufficiency of the valves in the segment between the two hands. Confirmation of the valvular insufficiency can be achieved by tapping proximally while palpating distally. This test can also be used to detect whether an enlarged tributary is in direct connection with the GSV or SSV by palpating over the main trunk and tapping lightly on the dilated tributary, or vice versa. The presence of a direct connection results in a palpable impulse being transmitted from the percussing to the palpating hand. As might be expected, these tests are far from infallible.

Perthes' Test

The Perthes' test has several uses, including distinguishing between venous valvular insufficiency in the deep, perforator, and superficial systems and screening for DVT. To localize the site of valvular disease, the physician places a tourniquet around the proximal thigh with the patient standing. When the patient walks, a decrease in the distension of varicose veins suggests a primary process without underlying deep venous disease because the calf muscle pump effectively removes blood from the leg and empties the varicose veins. Secondary varicose veins do not change caliber (if there is patency of the deep venous system) because of the inability to empty blood out of the veins as a result of impairment of the calf muscle pump. In the setting of a current DVT, they may increase in size. If there is significant chronic or acute obstructive disease in the iliofemoral segment, the patient may note pain (venous claudication) as a result of the obstruction to outflow through both the deep and superficial systems. The Perthes' test is now of more historical than actual clinical importance.

CLASSIFYING VENOUS DISEASE

The Swedish physician and scientist Carl von Linné published a classification of plants based on the number of stamina and pistils in 1735 in *Systema Naturae*. Today, classification of diseases is a basic instrument for uniform diagnosis and meaningful communication about the disease. In chronic venous disorders (CVD) reliance for too long has been placed on the clinical appearance of the superficial effects of CVD, such as spider veins, varicose veins, swelling, skin changes, and ulcerations, without requiring accurate objective testing of the venous system to substantiate the diagnosis. This practice has caused errors of diagnosis and has been largely responsible for the poor correlation of results between treatment methods. There have been several classifications in the past that have added to our understanding of CVD, but all lack the completeness and objectivity needed for scientific accuracy.

Clinical Classification

C0: No visible or palpable signs of venous disease

C1: Telangiectasias or reticular veins

C2: Varicose veins

C3: Edema

C4a: Pigmentation and/or eczema

C4b: Lipodermatosclerosis and/or atrophie blanche

C5: Healed venous ulcer

C6: Active venous ulcer

S: Symptoms including ache, pain, tightness, skin irritation, heaviness, muscle cramps, as well as other complaints attributable to venous dysfunction

A: Asymptomatic

Etiologic Classification

Ec: Congenital

Ep: Primary

Es: Secondary (postthrombotic)

En: No venous etiology identified

Anatomic Classification

As: Superficial veins

Ap: Perforator veins

Ad: Deep veins

An: No venous location identified

Pathophysiologic Classification

Basic CEAP:

Pr: Reflux

Po: Obstruction

Pr,o: Reflux and obstruction

Pn: No venous pathophysiology identifiable

Same as basic, with the addition that any of 18 named venous segments can be utilized as locators for venous pathology:

Superficial veins:

1. Telangiectasias/reticular veins
2. Great saphenous vein (GSV) above knee
3. GSV below knee
4. Small saphenous vein
5. Nonsaphenous veins

Deep veins:

6. Inferior vena cava
7. Common iliac vein
8. Internal iliac vein
9. External iliac vein
10. Pelvic: gonadal, broad ligament veins, other
11. Common femoral vein
12. Deep femoral vein
13. Femoral vein
14. Popliteal vein
15. Crural: anterior tibial, posterior tibial, peroneal veins (all paired)
16. Muscular: gastrocnemial, soleal veins, other

Perforating veins:

17. Thigh

18. Calf

TREATMENT OF VENOUS INSUFFICIENCY

The term venous insufficiency implies that normal functioning is deranged. Terms used to describe the various manifestations of venous insufficiency lend confusion to the general topic. Some of these terms, such as telangiectasias, thread veins, and spider veins are descriptive but imply different conditions. And it is in the chronic disorders, dominated by venous reflux through failed check valves causing hyperpigmentation, ulceration, and corona phlebectatica, where disorientation reigns. Some order can come from subscribing to a unifying theory of primary venous insufficiency and of a common theory of effects of an inflammatory cascade that clarify both situations.

The manifestations of simple primary venous insufficiency appear to be different from one another. However, reticular varicosities, telangiectasias, and major varicose veins are all elongated, dilated, and are tortuous. Investigations into valve damage and venous wall abnormalities eventually may lead to an understanding of the problem, and therefore, a solution by surgery or pharmacotherapy.

Scanning electron microscopy has shown varying degrees of thinning of the varicose venous wall. These areas of thinning coincide with areas of varicose dilation and replacement of smooth muscle by collagen, which is also a characteristic of varicose veins. Our approach to this has been to assume that both the venous valve and the venous wall are affected by the elements that cause varicose veins. We and others have observed that in limbs with varicose veins, an absence of the subterminal valve at the saphenofemoral junction is common. Further, perforation, splitting, and atrophy of saphenous venous valves have been seen both by angioscopy and by direct examination of surgical specimens.

Supporting the theory of weakness of the venous wall leading to valvular insufficiency is the observation that there is an increase in the vein wall space between the valve leaflets. This is the first and most commonly observed abnormality associated with valve reflux. Realizing these facts, our investigations have led us to explore the possible role of leukocyte infiltration

of venous valves and the venous wall as part of the cause of varicose veins. In our investigations of surgical specimens, leukocytes in great number have been observed in the venous valves, and wall and monoclonal antibody staining has revealed their precise identification as monocytes. Similar findings are present in the skin of patients with venous insufficiency.

SURGICAL TREATMENT

Removal of the Great Saphenous vein (GSV) from the circulation is one of two essential steps in treating lower limb varicose veins. Incompetent valves along the GSV allow blood to reflux down the vein and into its tributaries, transmitting high pressure into smaller tributaries, which become varicose as a result. Much emphasis has been placed on the correct technique of high sapheno-femoral ligation, in which meticulous attention is paid to identifying, ligating, and dividing all the tributaries of the GSV as they join the vein in the groin. It has always been a matter of surgical dogma that overlooking any of these allows continued reflux into the residual tributary and subsequent development of recurrent varicose veins.

A number of studies have confirmed that patients in whom the GSV is stripped tend to have fewer than those undergoing simple high ligation of the Sapheno-femoral junction (SFJ). Sarin et al. studied 89 limbs in 69 patients with LSV incompetence.

Legs were randomized to SFJ ligation with or without stripping, and evaluated by photoplethysmography (PPG), duplex scanning, clinical examination, and patient satisfaction. The follow-up period was 18 months. Significant differences in favor of the stripped group were found in all four parameters at final evaluation.

A similar study of 78 patients (110 limbs) was reported by Dwerryhouse et al. in 1999, with a longer follow-up period of five years. This demonstrated a significantly lower reoperation rate among patients undergoing GSV stripping (6%), as opposed to 20% in those undergoing high SFJ ligation alone.

Duplex scanning showed a much lower incidence of residual reflux in the remaining GSV when the proximal vein had been stripped to the knee than when it had not. However, the patient satisfaction rate was not significantly different between the two groups. Ninety percent of the stripped groups were satisfied as opposed to 87% in the nonstripped group ($p = ns$). A further study from Jones et al. came to similar conclusions.

One hundred patients (133 limbs) were randomized as before. After two years, 43% of those who had not had GSV stripping demonstrated recurrent varicose veins as opposed to

25% who had. There was a statistically significant difference.

NEOVASCULARIZATION

Of great importance was the fact that duplex scanning showed that neovascularization in the groin was the commonest cause of varicose recurrence. It was often seen in the ligation group that reflux through the neovascularization entered the residual saphenous vein and perpetuated the old varices while new ones developed. The authors concluded that by stripping the GSV, one was removing the run-off into which the new vessels could drain. Again, however, the satisfaction was broadly similar between the two groups: 91% in the stripped group and 87% in the unstripped.

All these authors concluded that stripping the long GSV gave better long-term results than simple high saphenous ligation. This appears to be true in terms of objective assessment of recurrence rates and in objective measurement of post-operative venous function but is not generally reflected in patient satisfaction rates, which tend to be similar whichever procedure is performed. This led Woodyer and Dormandy to reach a contrary conclusion—that stripping the LSV was a procedure based on surgical dogma, and one that did not confer subjective benefit to the patients so treated. This leads one to conclude that a better method of evaluation of treatment results should be developed.

NONSURGICAL TREATMENT

In recent years, endovenous ablation has been found to be safe and effective in eliminating the proximal portion of the GSV from the venous circulation, with even faster recovery and better cosmetic results than stripping. The two currently available methods used to achieve ablation of the GSV are the Closure© procedure using a radiofrequency (RF) catheter and generator (VNUS Medical Technologies, Inc., Sunnyvale, California), and the endovenous laser ablation (EVLT) procedure using a laser fiber and generator (various manufacturers). Both systems use electromagnetic energy to destroy the GSV in situ. One of the difficulties in evaluating reports of successful ablation of the Great Saphenous vein lies in the definition of success. Some, especially in the RF ablation reports, define success as “no reflux in any segment longer than 5 cm.” Some laser reports refer to success as “stable occlusion” or “reduction in reflux,” and Min has applied the much clearer standard of success as “no flow by color flow Doppler.” Those who report results have not used the life table method, which

takes into consideration drop outs and early and mid-term failures. Thus the reported favorable four and five year rates of elimination of reflux may be exaggerated.

The major difficulty with defining success as reduction or absence of reflux is that attempts to establish whether reflux is present in a portion of a previously closed GSV may be inaccurate. Also, most recurrent patency is seen in the proximal portion of the treated GSV. Therefore, distal compression of the closed portion of the GSV to identify reflux in a proximal segment is futile. Likewise, using the Valsalva maneuver is unreliable and lacks reproducibility. Finally, the importance of distinguishing a partially patent channel with flow, from one with reflux, is academic, since the valves are just as thoroughly destroyed as the rest of the vein wall.

CHEMICAL VENOUS CLOSURE

Some phlebologists have advocated liquid sclerotherapy of the saphenous vein, but the results of such treatment have been disappointing, and published long-term results are absent. Comparisons between liquid and foam sclerotherapy have been done and the results strongly favor foam.

Ultrasound-guided sclerotherapy (USGS) with foam must be considered as a completely new treatment of varicose veins. Although it needs proper training and some skill, it is simple, affordable, and extremely efficient.

Sclerosing agents produce a lesion of the venous wall, predominantly of the endothelium and, to a minor extent, of the media. The reaction that follows depends on the concentration of the agent and on the duration of the contact. If the venous diameter is greater than 3 mm, injections of liquid do not achieve this aim and dilution with blood quickly decreases their efficacy at short distances from the point of injection. Injections of foam have the advantage of a total filling of the vein, at least under 12 mm diameter. A further reduction in venous diameter can be obtained by leg elevation, compression with the hand, duplex probe or bandage, and venous spasm. In very large veins, foam will float over blood and induce a lesion of the upper venous wall, despite apparent correct filling of the vein observed on duplex, thus the importance of massaging and compression.

Making the foam is easy and quick. Based on the technique initially described by Tessari, it can be prepared with two 5 cc syringes and a three-way stopcock. Only detergent sclerosing agents can be used: Sotradecol and Polidocanol at any desired concentration from 0.25% to 3%. Microbubbles of foam sclerosing agents are hyperechogenic and represent an excellent contrast medium for ultrasound techniques. They appear as a shadow within the

lumen early, and like a hyperechogenic mass later with a acoustic shadow. Massaging the sclerosing agent to the desired part of the varicose network with the duplex probe or the hand is also very easily carried out. Progression from the varicose clusters to the GSV and then to the SFJ is always visible, provided a sufficient volume has been injected. Venous spasm usually is observed within minutes. The importance of the initial spasm has been emphasized in several studies and protocols.

Post-sclerotherapy compression is mandatory: on the varicose clusters for 48 hours, and then whole limb compression with 20–30 mmHg thigh-high medical elastic stockings. They must be worn during the daytime for at least 15 days. Patients must be examined both clinically and with duplex at 7 to 15 days.

The absolute risk of deep venous thrombosis is not confirmed. A few cases have been reported: most of them are gastrocnemius vein thrombosis, typically after telangiectasia and reticular vein sclerotherapy. Most frequent complications are visual disorders. These adverse reactions have been observed also with liquid sclerosing agents but their incidence is much higher with foam; they can be estimated at 0.5–1 per 100 foam sessions.

They are observed more frequently in patients suffering from migraine with visual aura. They usually reproduce this aura. The patho-physiology of this phenomenon has been questioned but has received no answer so far. The existence of a patent foramen ovale is the most likely explanation, as has been the liberation of toxic component associated with endothelial cell destruction (endothelin).

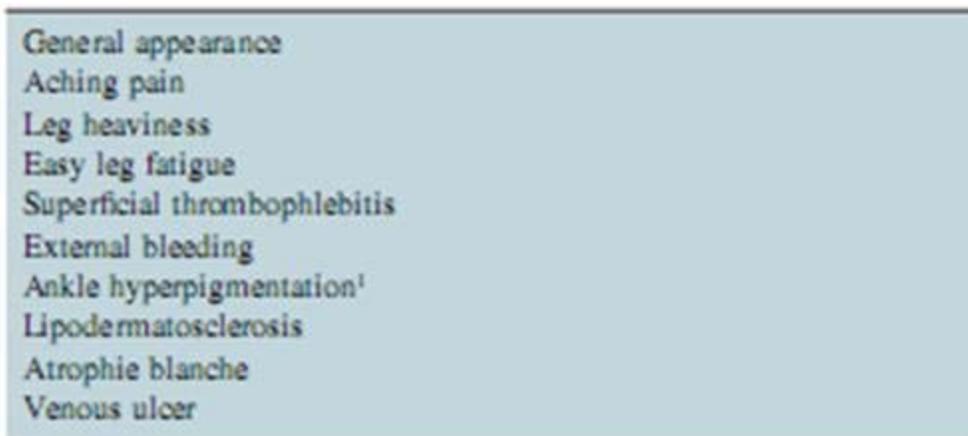

All published results demonstrate an immediate efficacy better than 80% in terms of immediate/primary venous occlusion. Repetition of injections in case of initial failure allows closure to approach 95% of efficacy with two to three sessions. Early and mid-term results demonstrate a recurrence rate of about 20%. The re-do injections remain as simple as primary injections and at least as efficient.

INVERSION STRIPPING OF THE SAPHENOUS VEIN

One of the cornerstones of surgery for varicose veins is removal of the Great Saphenous vein (GSV) from the circulation. This can be done using minimally invasive techniques described elsewhere in this volume, but specific indications for performing saphenous surgery remain. These are largely institutional and geographic but they justify the following exposition. Indications for intervention in primary venous insufficiency are listed in Table 4. Often, it is the appearance of telangiectatic blemishes or protuberant varicosities that stimulates

consultation. Ultimately, this may be the only indication for intervention.

Table 4. Varicose Veins: Indications for Intervention

General appearance
Aching pain
Leg heaviness
Easy leg fatigue
Superficial thrombophlebitis
External bleeding
Ankle hyperpigmentation ¹
Lipodermatosclerosis
Atrophie blanche
Venous ulcer

Characteristic symptoms include aching, pain, easy leg fatigue, and leg heaviness, all relieved by leg elevation, and worsened on the first day of a menstrual period. Other indications for intervention for venous varicosities include superficial thrombophlebitis in varicose clusters, external bleeding from high-pressure venous blebs, or advanced changes of chronic venous insufficiency such as severe ankle hyperpigmentation, subcutaneous lipodermatosclerosis, atrophie blanche, or frank ulceration. Symptoms are frequent throughout the CEAP Classes 1 through 6. Clinical Disability Scores parallel the clinical classification.

Objectives of treatment should be ablation of the hydrostatic forces of axial reflux and removal of the effects of hydrodynamic forces of perforator vein reflux. The latter can be accomplished by removal of the saphenous vein in the thigh and the varicose veins without specific perforating vein interruption. In France, the two most performed procedures recently were, respectively, high ligation + saphenous trunk stripping + tributary stab avulsion (71.9%) and high ligation + saphenous trunk stripping (17.3%). Isolated phlebectomy was done in 5.6%, high ligation + tributary stab avulsion + saphenous trunk preservation 2.8%, isolated high ligation 2.2%.

Ligation of the saphenous vein at the saphenofemoral junction has been practiced widely in the belief that this would control gravitational reflux while preserving the vein for subsequent arterial bypass. It is true that the saphenous vein is largely preserved after proximal ligation. Unfortunately, reflux continues and hydrodynamic forces are not controlled. Less reflux persists when the long saphenous vein has been stripped. There is a better functional outcome after stripping and fewer junctional recurrences. Randomized trials show efficacy of

stripping compared to simple proximal ligation.

Earlier comparisons of saphenous ligation versus stripping were flawed by today's standards. Subjective evaluation was the only means of measuring outcome for a time.

Duplex scanning came into use, verifying that stripping was superior to proximal ligation; this fact was supported by PPG. Despite those facts, it was acknowledged that the period of disability after stripping was greater than that after simple ligation. In attempts to decrease disability and improve efficacy, high tie was added to saphenous vein sclerotherapy, but foot volumetry showed that radical surgery, including stripping produced superior results.

Ultimately, attention became focused on saphenous nerve injury associated with ankle to groin stripping. It was concluded that nerve injury was reduced by groin to ankle stripping (see Figure 5). Preservation of calf veins by stripping to the knee was shown to reduce nerve injury and did not adversely affect early venous hemodynamic improvement.

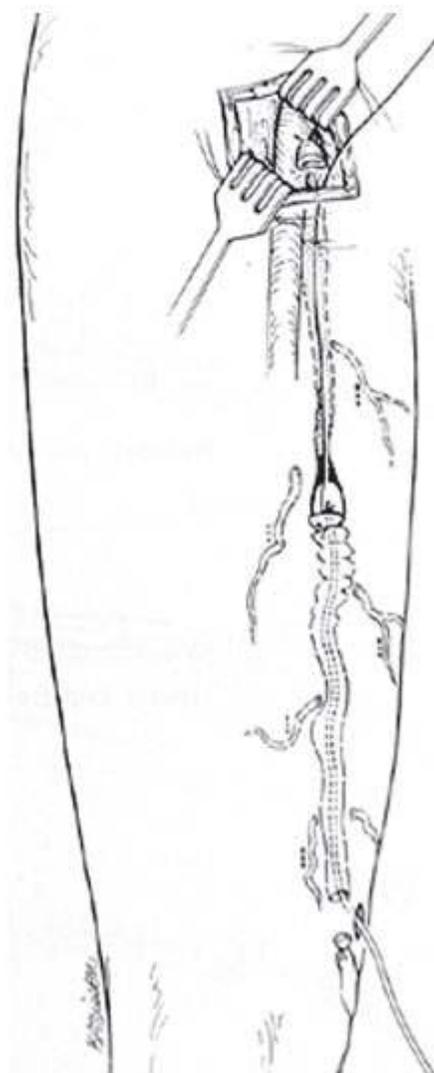

Fig. 5.

This fact is contrainuitive, and the subject deserves further study. Attempts to reduce nerve injury and simultaneously clean up varicose vein surgery led to use of the hemostatic tourniquet. In a study with level 1 evidence, it was shown that use of a hemostatic cuff tourniquet during varicose vein surgery reduces perioperative blood loss, operative time, and postoperative bruising without any obvious drawbacks.

Recurrent varicose veins after surgery are acknowledged to be a major problem for patients and society. Traditionally, it was thought that the most common reason for varicose recurrence was failure to perform an adequate saphenofemoral junction dissection (see Figure 6), or to correctly identify the saphenous vein for removal.

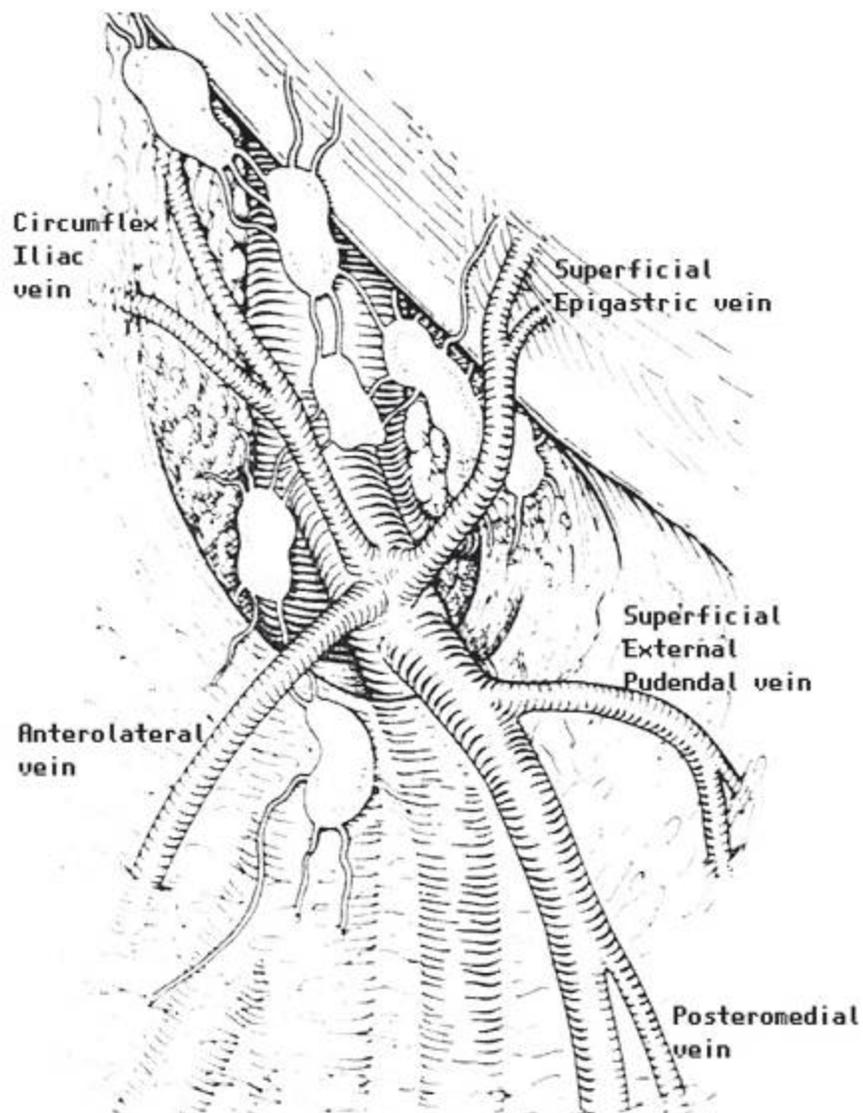

Fig.6. In the past, a proper groin dissection consisted of laying out each of the named saphenofemoral junction tributaries and dissecting them back beyond their primary tributaries. Now, this is acknowledged by most to be the strongest stimulus to neovascularization.

Duplex scans have clarified this situation and instead of technical error, some investigators are convinced that new vessel growth contributes to recurrent varicose veins. In particular, incomplete superficial surgery, at the saphenofemoral and saphenopopliteal junctions, is a less frequent cause of recurrent disease, and neovascular reconnection and persistent abnormal venous function are the major contributors to disease recurrence.

PREOPERATIVE PREPARATION

Over the years, much space has been given to clinical examination of the patient with varicose veins. Many clinical tests have been described. Most carry the names of now-dead surgeons who were interested in venous pathophysiology. This august history notwithstanding, the Trendelenburg test, the Schwartz test, the Perthes test, and the Mahorner and Ochsner modifications of the Trendelenburg test essentially are useless in preoperative evaluation of patients today.

The clinical evaluation can be improved by using hand-held Doppler devices. However, preoperative evaluation is best performed by means of duplex scanning and a focused physical examination. Our protocol for duplex mapping of incompetent superficial veins has been published. Although many cite cost considerations as a reason for omitting duplex evaluation, we believe that duplex scanning for venous insufficiency is in fact both simple and cost effective. Duplex mapping defines individual patient anatomy with considerable precision and provides valuable information that supplements the physician's clinical impression.

Three principal goals must be kept in mind in planning treatment of varicose veins: 1) the varicosities must be permanently removed and the underlying cause of venous hypertension treated; 2) the repair must be done in as cosmetic a fashion as possible; 3) complications must be minimized.

Current practice of treating the source of venous hypertension, the saphenous vein alone either by EVLT or VNUS technology, is inadequate. The patient's complaint, the varicose veins, must be addressed. This is as important as the physician's knowledge that the sources of venous hypertension must be addressed.

To speak of permanent removal of varicosities implies that all potential causes of recurrence have been considered and that surgery has been planned so as to address them. There are four principal causes of recurrence of varicose veins, of which three can be dealt with at the time of the primary operation.

One cause of recurrent varicosities is failure to perform the primary operation in a correct fashion. Common errors include missing a duplicated saphenous vein and mistaking an anterolateral or accessory saphenous vein for the greater saphenous vein. Such errors can be eliminated by careful and thorough groin dissection. Accordingly, failure to do a proper groin dissection has long been held to be a second principal cause of recurrent varicose veins. It is now known, however, that such dissection causes neovascularization in the groin, leading to recurrence of varicose veins. A third cause of recurrent varicosities is failure to remove the greater saphenous vein from the circulation. As mentioned earlier, reasons often cited for this failure is the desire to preserve the saphenous vein for subsequent use as an arterial bypass. It is clear, however, that the preserved saphenous vein continues to reflux and continues to elongate and dilate its tributaries. This produces more and larger varicosities. A fourth cause of recurrent varicosities is persistence of venous hypertension through nonsaphenous sources—chiefly, perforating veins with incompetent valves. Muscular contraction generates enormous pressures that are directed against valves in perforating veins. Venous hypertension induces a leukocyte endothelial reaction, which, in turn, incites an inflammatory response that ultimately destroys the venous valves and weakens the venous wall. The perforating veins most commonly associated with recurrent varicosities are the midthigh perforating vein, the distal thigh perforating vein, the proximal anteromedial calf perforating vein, and the lateral thigh perforating vein, which connects the profunda femoris vein to surface varicosities.

Finally, there is a fifth cause of recurrent varicosities, which is out of control of the operating surgeon—namely, the genetic tendency to form varicosities through development of localized or generalized vein wall weakness, localized blowouts of venous walls, or stretched, elongated, and floppy venous valves.

SAPHENOUS SURGERY

For varicose vein surgery to be successful, two tasks must be accomplished. The first is ablation of reflux from the deep to the superficial veins, including the saphenofemoral junction, the saphenopopliteal junction, and midthigh varices from the Hunterian perforating vein. Accomplishment of this task is guided by the careful preoperative duplex mapping of major

superficial venous reflux.

The second task is removal or destruction of all varicosities present at the time of the surgical intervention. Accomplishment of this task is guided by meticulous marking of all varicose vein clusters. A number of options are available for surgical treatment of varicose veins. Regardless of the specific approach taken, the general technical objectives are the same: 1) ablation of the hydrostatic forces of axial saphenous vein reflux (see Figure 7) and 2) removal of the hydrodynamic forces of perforator vein outflow.

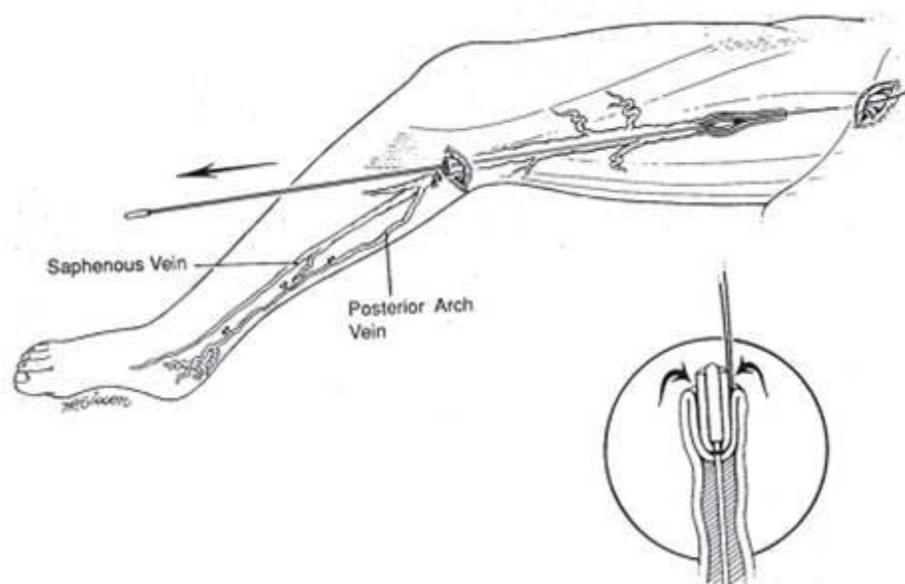

Fig. 7. Inversion stripping of the saphenous vein was an important step forward in minimizing soft tissue trauma while accomplishing the principal objective of ablating hydrostatic venous hypertension by removing saphenous reflux. Tearing of the vein during its removal flawed its performance.

Ankle-to-groin stripping of the saphenous vein has been a dominant treatment of varicose veins over the past 100 years. One argument against routine stripping of the leg (i.e., ankle-to-knee) portion of the saphenous vein is the risk of concomitant saphenous nerve injury. Another argument is that whereas the objective of saphenous vein removal is detachment of perforating veins emanating from the saphenous vein, which are seen in the thigh, the perforating veins in the leg are actually part of the posterior arch vein system rather than the saphenous vein system. This latter argument notwithstanding, preoperative ultrasonography frequently shows that the leg portion of the saphenous vein is in fact directly connected to

perforating veins. Therefore, removal of the saphenous vein from ankle to knee should be a consideration in every surgical case.

OPERATIVE TECHNIQUE

The surgical approach taken must be individually tailored to each patient and each limb. Groin-to-knee stripping of the saphenous vein should be considered in every patient requiring surgical intervention. In nearly all patients, this measure is supplemented by removal of the varicose vein clusters via stab avulsion or some form of sclerotherapy.

Preoperative marking, if correctly performed, will have documented the extent of varicose vein clusters and identified the clinical points where control of varices is required. Incisions can then be planned. As a rule, incisions in the groin and at the ankle should be transverse and should be placed within skin lines. In the groin, an oblique variation of the transverse incision may be appropriate. This incision should be placed high enough to permit identification of the saphenofemoral junction.

Generally, throughout the leg and the thigh, the best cosmetic results are obtained with vertical incisions. Transverse incisions are used only in the region of the knee, and oblique incisions are appropriate over the patella when the incisions are placed in skin lines.

A major cause of discomfort and occasional permanent skin pigmentation is subcutaneous extravasation of blood during and after saphenous vein stripping. Such extravasation can be minimized by applying a hemostatic tourniquet after Esmarch exsanguination of the limb. The pressure in the hemostatic tourniquet should be between 250 and 300 mm Hg, and the tourniquet should not be in place for longer than one hour. If a tourniquet is not used, the entire operation on one limb can be performed with the limb elevated 30° so that the major varicose clusters are higher than the heart. In addition, hemostatic packing can be placed into the saphenous vein tunnel.

The practice of identifying and carefully dividing each of the tributaries to the saphenofemoral junction has been dominant over the past 50 years. The rationale for this practice has been that it would be inadvisable to leave behind a network of interanastomosing inguinal tributaries. Accordingly, special efforts have been made to draw each of the saphenous tributaries into the groin incision so that when they are placed on traction, their primary and even secondary tributaries can be controlled. The importance of these efforts has been underscored by descriptions of residual inguinal networks as an important cause of varicose vein recurrence. Currently, however, this central practice of varicose vein surgery is under

challenge, on the grounds that groin dissection can lead to neovascularization and hence to recurrence of varicosities.

Preoperative duplex studies have already demonstrated incompetent valves in the saphenous system, and a disposable plastic stripper can be introduced from above downward; alternatively, a metal stripper can be employed. Both of these devices can be used to strip the saphenous vein from groin to knee via the inversion technique. This approach should reduce soft tissue trauma in the thigh.

In the groin, the stripper is inserted proximally into the upper end of the divided internal saphenous vein and passed down the main channel through incompetent valves until it can be felt lying distally approximately 1 cm medial to the medial border of the tibia at a point approximately 4 to 6 cm distal to the level of the tibial tubercle. The saphenous vein is anatomically constant in this location, just as it is in the groin and ankle. If the saphenous vein is removed from the groin to this level, both the midthigh perforating vein, which usually enters the saphenous vein, and the most distal incompetent perforating veins, which are in the distal third of the thigh, will be treated. A small incision is made over the palpable distal end of the stripper. The saphenous vein will subsequently be divided through this incision, and the stripper and the inverted vein will be delivered through it. In exposing the saphenous vein at knee level, the superficial fascia must be incised so as to enter the saphenous compartment. If the stripper passes unimpeded to the ankle, it can be exposed there with an exceedingly small skin incision placed in a carefully chosen skin line. Passage of the stripper from above downward to the ankle serves to confirm the absence of functioning valves, and stripping of the vein from above downward is unlikely to cause nerve damage. At the ankle, the vein should be carefully and cleanly dissected to free it from surrounding nerve fibers. If this is not done, saphenous nerve injury will result, and the patient will experience numbness of the foot below the ankle.

Stripping of the saphenous vein has been shown to produce profound distal venous hypertension. This occurs in virtually every operation, even when the limb is elevated. Therefore, after the stripper is placed, one should consider performing the stab avulsion portion of the procedure before the actual stripping maneuver.

Incisions to remove varicose clusters vary according to the size of the vein, the thickness of the vein wall, and the degree to which the vein is adhering to the perivenous tissues. In general, vertical incisions 1 to 3 mm in length are appropriate, except in areas where skin lines are obviously horizontal. Successive incisions are spaced as widely as possible. Varicosities are exteriorized by means of hooks or forceps. Particularly useful for this purpose are the specially

designed vein hooks known by the names Varady dissector, Mueller hook, and Oesch hook. These devices efficiently detach perforating veins from their tributary varicose clusters. Dissection of each perforating vein at the fascial level is not required, and in fact may be cosmetically undesirable. There is no need to ligate or clip the ends of each vein: the combination of leg elevation, trauma-induced venospasm, and direct pressure typically ensures adequate hemostasis. Once exteriorized, the varicosity is divided and avulsed for as long a length as possible. After avulsion, skin edges are approximated with tape or with a single absorbable monofilament suture.

Phlebectomy techniques for varicose clusters have been markedly refined by experienced workers in Europe.

Once the stab avulsion portion of the procedure is complete, the previously placed stripper is pulled distally to remove the saphenous vein. Although plastic disposable vein strippers and their metallic equivalents were designed to be used with various-sized olives to remove the saphenous vein, in fact, a more efficient technique is simply to tie the vein to the stripper below its tip so that the vessel can then be inverted into itself and removed distally. To decrease oozing into the tract created by stripping, a 5 cm roller gauze soaked in a 1% lidocaine-epinephrine solution is attached to the stripper by using the ligature fastening the saphenous vein to the device (see Figure 25.4). Thus, inversion stripping is accompanied by hemostatic packing. The hemostatic pack, which lies within the saphenous vein, can be pulled into the tract with minimum tissue trauma; when it is not inverted into the vein itself, it can act as an obturator to facilitate removal of the saphenous vein without tearing. As the vein is removed by inversion, the gauze is left in place for hemostasis while the remainder of the surgical procedure is being completed.

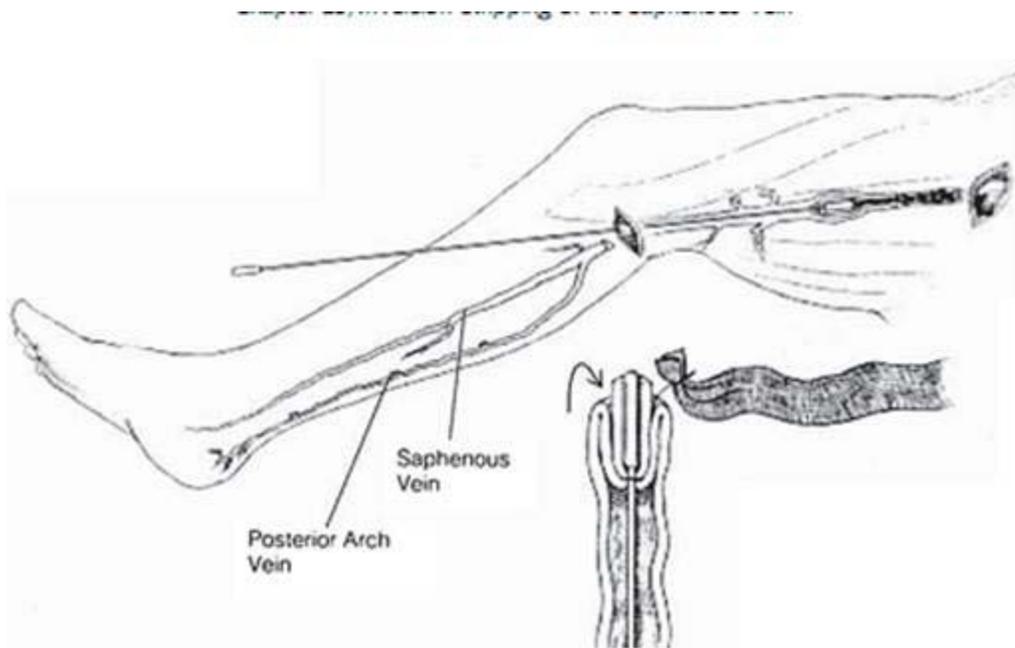

Fig. 8 . Adding a hemostatic pack to inversion stripping corrected the principal flaw in inversion stripping, the tearing of the saphenous vein. The pack acted as an obturator, which insured total vein removal. In most instances, the pack entered the vein as it was being removed, thus minimizing the soft tissue trauma.

POST-THROMBOTIC SYNDROME

Postthrombotic syndrome (PTS) is a frequent sequel to deep venous thrombosis (DVT). Awareness of this long-term debilitating complication is low among treating physicians whose main focus is the acute embolic complications of DVT. PTS may take years and even decades to fully evolve when the patient is no longer in the care of the original treating physician. Recurrent DVT that may occur years later after the initial event is a known risk factor for the development of PTS. Serial follow up of patients after onset of DVT has provided important new perspectives on many aspects of PTS. After a bout of DVT, only a third of the patients are asymptomatic long term; but the other two thirds have PTS, half of them severe. The direct and indirect costs of this disease that affects all adult age groups is estimated to be enormous, arousing the interest of public health planners.

CLINICAL FEATURES

Major symptoms are limb pain, swelling, and stasis skin changes including ulceration. Recurrent thrombophlebitis and recurrent cellulitis, the latter related to underlying tissue edema, are less well known and less frequent features. Symptoms are present in varying combinations and severity in individual patients. Pain is an important but variable component of the symptom complex. Limb swelling may be described by the patient as severe because it is painful even though only mild pitting is evident on examination. Some patients may not even be aware of limb edema evident to the examiner because it is pain free. Pain is absent in about 20% of patients. In about 10% of patients, pain may be the only symptom without other signs; a diagnosis of PTS may altogether be missed, because the limb looks normal. Severity of pain present may be exaggerated or understated by the patient due to individual variations in pain tolerance and other socioeconomic factors such as work situation; daily or frequent use of nonsteroidal or narcotic dependency for pain relief may not be readily disclosed unless specifically questioned. Other essential elements of history may not be readily forthcoming as well. For example, previous DVT or severe trauma to the limb may not be volunteered because the remote event years ago had been forgotten or not considered relevant to current complaints. Because of these variables, a detailed comprehensive history-taking with leading questions is essential for proper assessment; clinical features detected on examination should be recorded and graded for severity during initial and follow-up visits for proper assessment of outcome.

All components of relevant history and physical examination preloaded on a handheld device is a useful guide to those who see these patients only infrequently. The CEAP classification and Venous Severity Scoring endorsed by the vascular societies can serve as readily usable templates for this purpose. In our own system, we have made some additional enhancements that we find useful. Pain is measured on a visual analogue scale, a simple reliable measure of pain that can be used for outcome assessment as well. Limb swelling is variable throughout the day; limb measurement of swelling should be carried out at the same time of the day to be valid for follow-up assessment. Quality of life (QOL) measurements provide a view of outcome from the patient's perspective. The degree of disability and social constraint imposed by this disease can be surprising. Many QOL forms (e.g., CIVIQ) are brief enough for routine use.

DIFFERENTIAL DIAGNOSIS

A clinical diagnosis of chronic venous insufficiency is readily apparent from history and physical examination in most cases but other rarer causes with somewhat similar clinical features have to be borne in mind: Periarteritis nodosa, ruptured Baker's cyst, rheumatoid arthritis, gout, Marjolin's ulcer, arterio-venous malformations of the calf muscles, adverse drug reactions with limb pain and swelling, acanthoma nigricans, pyoderma, and numerous other dermatological and systemic conditions. As venous insufficiency is common, particularly among the elderly, mixed pathologies that aggravate venous symptoms do occur. Combined arterial/venous insufficiency is not uncommon in the elderly; attention to the arterial component first is usually recommended. Differentiating primary from PTS may not be easy and mixed presentations occur as the following discussion on pathology indicates. Differentiation cannot be made on clinical grounds alone as history and physical findings may be similar including the appearance and size of ulcers. About 30% of DVT are estimated to be silent. In others DVT following trauma or surgery is simply missed as symptoms are submerged by expected postoperative pain—a common occurrence following orthopedic procedures on the hip or knee or for treatment of fractures. Patients with deep valvular insufficiency whether primary or post-thrombotic not infrequently present with new onset of acute calf pain and increased swelling in the context of ongoing chronic symptoms. In some, new or recurrent thrombosis is found. In others, no new thrombus is found; the symptoms are presumably due to decompensation of the calf pump from minor injury, low grade cellulitis or other obscure insult that disturbs the equilibrium of the calf pump. A diagnosis of PTS vs primary venous insufficiency is academic from the surgical viewpoint as the approach is the same regardless.

But a diagnosis of PTS may have implications for long-term anticoagulation. In many cases, further investigations may provide helpful clarification.

PATHOLOGY

Our current view of PTS pathology is strongly influenced by the work of Strandness and colleagues. Before then, post-thrombotic clinical syndrome had been viewed as primarily related to the development of reflux. In a remarkable series of landmark papers, these authors showed that the dominant pathology was a combination of obstruction and reflux even though isolated obstruction and reflux occurred in some. The location and progression of post-thrombotic reflux followed by serial duplex were unexpected and intriguing. Reflux occurred not only in segments involved by thrombus but also in segments remote from them. Reflux occurred and progressed over time not only in deep venous segments distal to the thrombotic segment but also in segments proximal; in the distal segments, dilatation of the valve station due to cephalad obstruction was not found to be the cause of reflux. The fact that reflux occurs and progresses over time in superficial as well as deep valves proximal to the obstructed segment suggests a different (maybe cytokines), as yet poorly understood, mechanism.

Some patients present with femoral valve reflux and thrombosis in the distal femoral popliteal segment or even the calf. This clinical profile could be due to reflux stasis-induced distal thrombosis. Repair of the valve reflux can abate recurrent thrombosis. Similar type of clinical presentation also can result from evolution of de novo reflux above the thrombotic segment as described by Strandness and colleagues. Perivenous and mural fibrosis is a feature of these valves with constriction and foreshortening of the valve station (see Figure 9). The valve cusps themselves are redundant and reflexive apparently as a result of the fibrotic wall changes. The fibrotic valve station is somewhat smaller than the classic primary valve, but the cusps themselves appear normal but redundant and can be repaired like the primary valve using direct repair techniques. A plausible explanation for these features and perhaps for the remote reflux described by Strandness's group is that perivenous and mural fibrosis may extend beyond the thrombosed segment to involve adjacent segments of preserving valve cusps, but inducing secondary reflux from valve station restriction.

Valves may also escape destruction because the thrombus in the resident segment lyses, but not without inducing fibrotic changes as described.

'SECONDARY' VALVE REFLUX

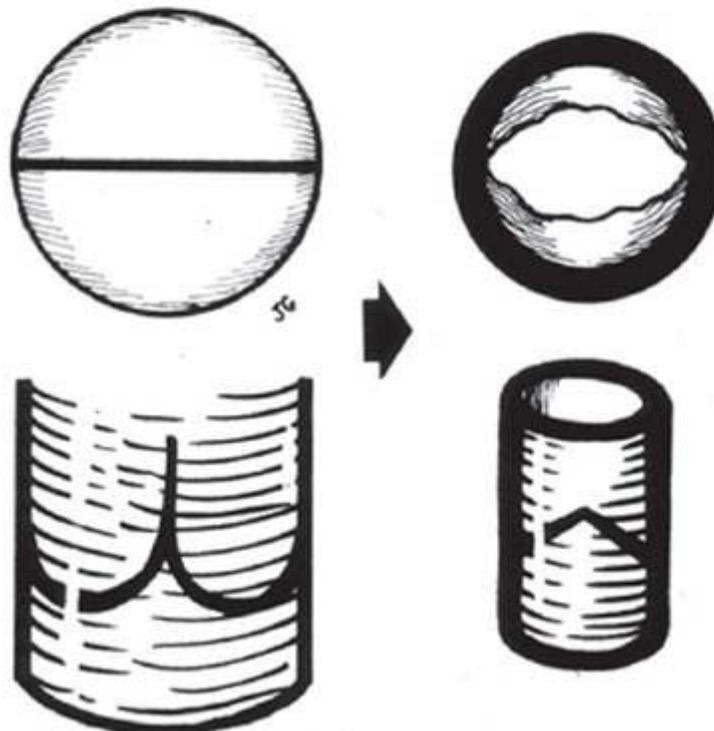

Fig. 9. A possible mechanism for the production of valve redundancy and reflux in post-thrombotic valve stations. Valve station fibrosis may lead to luminal constriction resulting in secondary valve leaflet redundancy and reflux. Foreshortening of the valve station may lead to widening of the commissural valve angle, contributing further to development of reflux.

INVESTIGATIONS

A comprehensive set of investigations are necessary for proper management of patients, particularly if invasive or other surgical intervention is contemplated. The aim is to clarify the pathology, identify the sites and nature of pathology, and grade its severity.

Duplex

Duplex is the initial and in many centers the only technique used. It has many deficiencies when used alone in assessment. As a qualitative tool, it can detect local reflux but cannot grade it nor can it adequately provide a measure of the overall severity of reflux in the

limb when multiple segments are involved. Valve closure time (VCT) has received much attention as a quantitative tool in this regard. Though it can identify reflux in a particular segment, VCT has poor correlation with the severity of reflux present. Trivial reflux may be associated with prolonged VCT and conversely high grade reflux may have only slightly prolonged VCT. Peak reflux velocity has a better correlation, but not to a degree that is clinically useable. At present relatively crude indices such as multisegment score (number of refluxive segments) or the presence of axial reflux are the best measures available. Iliac vein outflow obstruction, an important contributor to PTS, is frequently impervious to duplex.

Venography

Unlike duplex, ascending venography provides a more composite view of venous pathology below the inguinal ligament. Post-thrombotic changes, segmental occlusions, and collateral patterns are readily apparent. The profunda femoris vein is the major natural collateral pathway in femoral stenoses and occlusions. This has an embryologic basis as the profunda femoris is the early axial vein receding to the mature pattern later in embryologic development. A putative profunda-popliteal connection apparently exists as a high resistance embryologic residue; profunda collateral flow can be observed as early as a few hours after onset of acute DVT in venograms. In chronic femoral vein occlusions, the profunda enlarges to the same caliber as the normal femoral vein (see Figure 11). This pattern of complete axial transformation of the profunda femoris vein occurs in about 15% of postthrombotic limbs. Reflux may result from enlargement of the profunda valve station and may be severe with symptoms. Lesser degrees of profunda enlargement can be found in other cases where the femoral vein is not totally occluded but is stenotic.

Because the direction of collateral flow in the profunda is the same as natural flow direction in the vessel, it is very efficient. Once fully developed, the profunda fully compensates for the loss of femoral flow with few residual clinical symptoms from outflow obstruction. In iliac vein occlusions, collateral flow is mainly through tributaries of the iliac vein itself, requiring reversal of normal flow direction. Collateral flow seems to be less efficient and residual outflow obstruction is present in nearly half the cases with iliac occlusions.

These differential patterns of collateral development and function have clinical import. In patients with symptoms of outflow obstruction, iliac vein pathology is likely to be the culprit even if associated femoral vein occlusion is more readily seen on ascending venography. Ascending venography is inadequate for assessment of the iliac vein and the vena cava due to

contrast dilution; stenotic lesions may easily be missed.

Fig. 11. Axial transformation of profunda femoral vein through a large profunda-popliteal connection. The femoral vein is largely occluded with the distal end seen as a stump.

Transfemoral venography is the procedure of choice for pelvic venous assessment. Exercise femoral venous pressures can be concurrently measured, which can be helpful in grading severity of outflow obstruction. Descending venography can also be performed at the same time to define the architecture of femoral valves. Descending venography is no longer used for grading reflux due to lack of specificity.

A common pattern in severely post-thrombotic limbs is where the entire outflow appears to occur through the superficial veins with nonvisualization of deep veins giving the appearance of wiped-out deep system. This is invariably an artifact of technique. In most such cases a patent but post-thrombotic deep system with numerous collateral elements can be demonstrated on descending venography (see Figure 12). Presumably, there is a positive gradient across

superficial to deep venous connections in these cases that contrast flow preferentially is restricted to the superficial system. The collateral contribution of the superficial system in such cases is negligible. Since the deep system is patent, reconstructive procedures can be planned despite the spurious appearance on ascending venography.

Several authors beginning with Rokitanski have documented the development of a dense perivenous sheath in postthrombotic iliac veins. This prevents or retards the development of collaterals. Surgical attempts have been made to remove the sheath for improving flow. The venographic appearance in such cases is one of diffuse stenosis without collaterals. Iliac vein pathology is easily missed in such cases, especially with ascending venography. With transfemoral venography, the diffuse lesion can be quite evident or subtle requiring measurements of vein diameter, which is seldom practiced. Because of this and other factors cited earlier, the sensitivity of venography in iliac vein pathology is only in the order of 60%.

Fig. 12. Ascending venogram opacifies only superficial network (right). The deep system appears wiped out. This is often a technical artifact ample deep venous elements are demonstrated on descending

venography (left).

Intravascular Ultrasound (IVUS)

Intravascular ultrasound is superior to venography in the assessment of post-thrombotic iliac vein and the inferior vena cava. Perivenous and mural fibrosis, stenoses and trabeculae are readily seen. It is invaluable in iliac vein stent placement.

Lymphangiography

About 30% of patients with deep venous insufficiency have lymphographic abnormalities such as pooling and delayed or absent lymphatic transport. Most are thought to be secondary to venous pathology from lymphatic exhaustion or damage. Some may be reversible with correction of venous pathology. Lymphographic information has prognostic value in resolution of leg swelling and affected patients may be adequately forewarned before interventions.

Airplethysmography (APG)

Measurement of ejection fraction and residual volume have been suggested as indirect indices of outflow obstruction. In our own and others' experience, specificity and sensitivity have been inconsistent. VFI appears to be a useful measure of reflux.

Ambulatory Venous Pressure Measurement

Ambulatory venous pressure measurement provides a global index of venous function in the limb encompassing multiple components. Post-exercise pressure (% drop) has an inconsistent relationship to the severity of outflow obstruction presumably because of the variability of calf pump efficiency. The recovery time or venous filling time (VFT) has been useful in assessing severity of postthrombotic pathology and reflux. A postoperative VFT of >5 seconds bodes well for a good surgical outcome; a VFT of <5 seconds the opposite. The mean improvement in VFT after successful repairs with good clinical outcome is generally in the order of about 6 ± 4 (SD) seconds. After successful valve repair, postoperative VFT does not reach normal levels in many patients. VFT is influenced not only by reflux but a

multiplicity of other factors. Compliance of the conduit below the valve profoundly affects VFT even more than reflux at the valve. Failure to normalize or substantially improve VFT is probably related to the poor venous compliance in post-thrombotic extremities.

Measurement of Outflow Obstruction

Reduced or absent phasicity on duplex examination is often indicative of outflow obstruction at the iliac vein level, the information being qualitative. There are no reliable methods of functionally quantifying and grading outflow obstruction at the present time. Plethysmographic outflow fraction measurement such as with strain gauge technique and APG yield unacceptably high false positives due to compliance changes in the post-thrombotic calf; a reduced outflow fraction (<50%) results from subpar emptying of the venous pool from poor compliance as often as from outflow obstruction per se. And poor compliance may be present without obstruction. A reduced outflow fraction is indicative of post-thrombotic changes, not necessarily obstruction.

Pressure-based tests to detect and grade severity of obstruction such as arm/foot venous pressure differential with reactive hyperemia, exercise femoral venous pressures measurement, and intraoperative femoral vein pressure measurement with papavarine are positive only in about a third of cases. Assessment of outflow obstruction currently rests entirely on morphologic methodology (IVUS) restricted to the iliac vein segment.

TREATMENT

Compression Therapy

Compression therapy is the oldest and until recently the only therapeutic option available to treat PTS. It has been reported anecdotally to be ineffective in PTS but no systematic study has been undertaken. Compression therapy remains the initial approach in chronic venous disease including PTS. Some patients do fail compression therapy despite faithful compliance. Noncompliance, however, is the major cause of compression failure and recurrent symptoms. Noncompliance is high even in cold climates as documented in several community surveys. Longerm supervision or monitoring by health care workers has been advocated to improve compliance. However, noncompliance is high even under supervision. The reasons for noncompliance are many—tightness or fit (cutting off circulation), warm

weather, lack of efficacy, contact dermatitis, recurrent cost and inability to apply stockings due to frailty or arthritis are among the many reasons/excuses cited by patients. But the main underlying reason, often unstated, appears to be the restrictions and negatives of compression regimens in today's image-conscious world with expectations of an unrestricted lifestyle. Thus compression is a quality of life issue from the patient's viewpoint. Demands for compliance are unlikely to succeed after previous entreaties have failed and may not be appropriate when therapeutic alternatives have become available. Compression should be viewed not as an end itself, but complementary to the extent patients are willing to use them. Compression should be considered a failure regardless of the cause including noncompliance if symptom relief is not obtained after trial over a reasonable period of time, say three to six months depending on the clinical and socioeconomic situation of the patient. Worsening of symptoms or onset of complications such as recurrent infections during the trial period are also considered failures. Some patients are not candidates for compression therapy at all due to comorbidities (e.g., arthritis, frailty, or arterial compromise) or special work situations. Nonresponders should be offered alternatives, not life-long gunna boot regimens as was the case before by necessity, and continues to be so in many parts of the world due to a conservative philosophy of health care delivery.

Saphenous Vein Ablation

There has been traditional advice against saphenous ablation in the presence of deep venous obstruction (secondary varices) to preserve its collateral contribution. The collateral contribution of saphenous vein in the presence of deep venous obstruction is insignificant. Stripping of a refluxive saphenous vein in PTS cases can provide significant symptom benefit by eliminating the reflux component without jeopardizing the limb. Stripping can be easily combined with valve reconstruction in the femoral area. The newer minimally invasive techniques of saphenous ablation are suitable alternatives as well and are easily combined with iliac vein stent placement when indicated

Valvuloplasty

In PTS patients, direct femoral or popliteal valve repair can be performed if the basic valve architecture is preserved. Eriksson stressed the importance of profunda valve repair in post-thrombotic cases due to the frequent presence of collateral reflux. We prefer an external or

transmural technique without a venotomy for these cases as they are faster and hence multiple repairs (i.e., femoral and profunda) can be performed in a single sitting; and repairs can be carried out even in constricted or small valve stations. The internal technique is disadvantaged in comparison.

Trancommissural technique, which closes the wide valve angle present at the commissure and simultaneously tightens the lax valve cusps by transmural sutures that can be placed blindly in a reliable fashion. The first step in the procedure is to carry out an adventitial dissection to peel away the fibrous sheath surrounding the valve station. Valve attachment lines should become visible after the dissection. They should be defined in their entirety, which is necessary for placement of trancommissural sutures. Though the sutures are placed blindly, adherence to the technique as described in the original publication will result in technical success of >95%.

Absent or interrupted valve attachment lines invariably indicate cusp dissolution or damage beyond direct repair. In such cases one should proceed forthwith with axillary vein transfer without wasting time on performing a venotomy in a futile search for repairable valve cusps.

Axillary Vein Transfer

Axillary vein transfer is the mainstay of repair in PTS cases when direct valve repair is not feasible due to damage to the valve cusps. Seemingly a simple technique, it is in fact, quite demanding, requiring precise execution. Proctored learning is recommended to achieve consistently good results. The transferred valve should match the size of the native valve station being reconstructed. In most cases, the axillary vein is the preferred donor site to obtain a good size match. In a minority, the proximal brachial vein may also be suitable in size. We approach the axillary-brachial veins through a transverse incision in the armpit along the skin crease; exposure of 5 to 6 cm length of axillary vein segment will require ligation and division of three or more tributaries in the area. One or more valves will then come into view. We have not found preoperative duplex examination useful in locating a transferable valve. The valve with a good size match is chosen for transfer. A valve high up in the axilla at or near the first rib is consistently present and is the largest. This may require additional dissection for exposure. The chosen valve is then tested for competence by negative (emptying the infravalvular segment) and positive (squeezing the supra-avalvular segment) strip tests. About 40% of axillary valves

will fail the strip tests, in which case they should be repaired by the transcommissural technique preferably in situ or on the bench before transfer. A 4 cm vein segment housing the valve is excised and the ends of the remaining vein ligated. A lesser length will interfere with later anastomoses as the excised segment shrinks, risking the valve cusps being caught up in the suture lines. Reconstruction of the donor vein is not required; outflow obstructive symptoms in the donor limb are extremely rare. The transferable valve is dropped in cold balanced salt solution for a few minutes and then transferred to the recipient site. A 1 cm segment of the recipient vein is excised, which results in retraction of the cut ends leaving a longer gap. The axillary valve is transferred in proper orientation and the proximal anastomosis is performed first. Interrupted 6° monofilament permanent sutures should be used throughout. Continuous sutures, howsoever expertly applied, will result in postoperative suture line stenosis as the native and transferred vein segments dilate to their normal caliber, freed of intraoperative spasm. Once the upper anastomosis is completed, the valve should be retested for competence by the strip tests. Some axillary valve sinuses are shallow and are prone to de novo reflux with minor distortions of architecture that may occur during the transfer procedure. A transcommissural repair may then be required at this stage to achieve perfect competence. Before starting the distal anastomosis, the distal end of the recipient vein should be trimmed to match the length of the donor segment put on a mild stretch. A slack or overstretched donor segment will result in reflux. Proper rotational orientation of the transferred segment is crucial. There should be no hesitancy to take down and redo the distal suture line if imperfections or reflux is discovered after completion. Final positive and negative strip tests are performed to assure competence. The axillary vein has a thinner muscle layer than the native recipient vein because of the higher orthostatic pressures prevalent in the latter. This may result in gradual dilatation of the transferred axillary vein segment with onset of reflux. This problem encountered in early experience was addressed by placing a prosthetic sleeve around the transferred vein segment. Currently an 8 to 10 mm PTFE sleeve, 3 cm long, is split open and sutured back as a loose fitting sleeve around the transferred axillary valve with one or two anchoring sutures to the adventitia to prevent migration. Slipping an unopened sleeve over the lower end of the transferred segment before beginning the distal suture line may obscure rotational orientation of the transferred valve resulting in reflux after completion of the suture line and is to be avoided. The incision is closed with a closed drainage system. Penrose drainage is provided for the axillary incision. To avoid compression of the repair by fluid collection in a tight space, only the superficial fascia is closed with interrupted sutures and the deep fascia is left open.

In trabeculated post-thrombotic veins, modifications of the basic technique are

necessary. The trabeculae at the site of proximal and distal suture lines are excised (see Figure 13, 14, 15) to create a single lumen at the site for anastomoses.

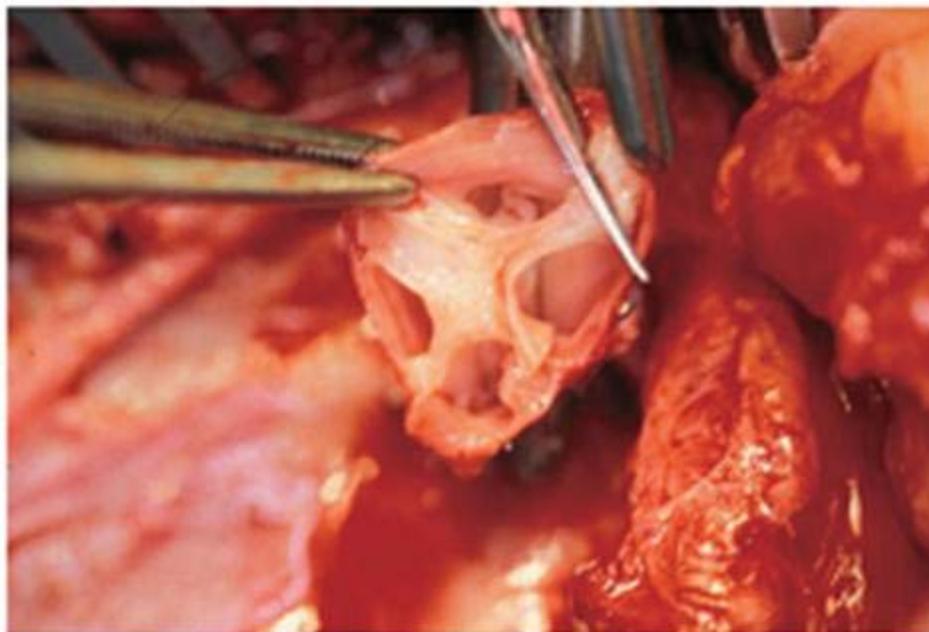

Fig. 13.

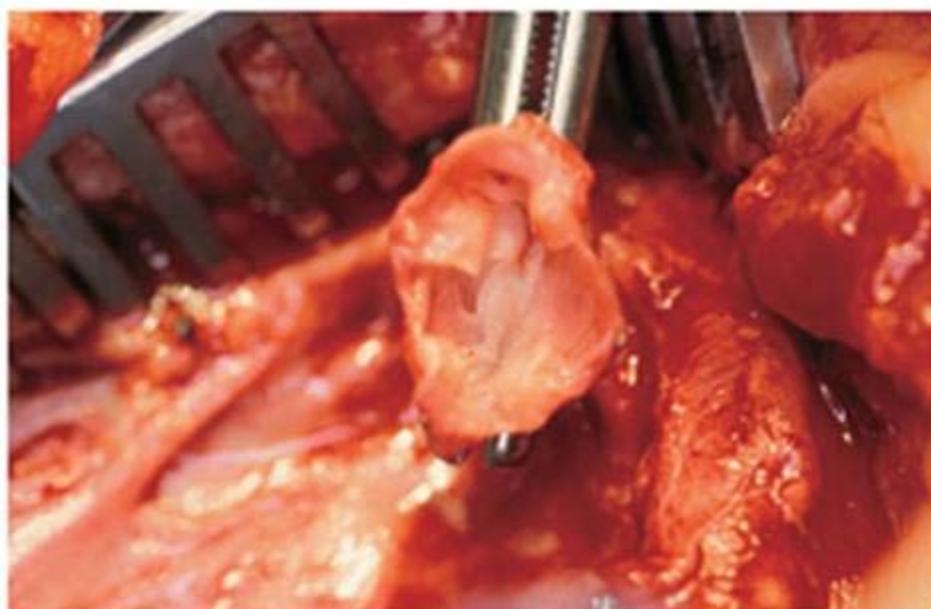

Fig. 14.

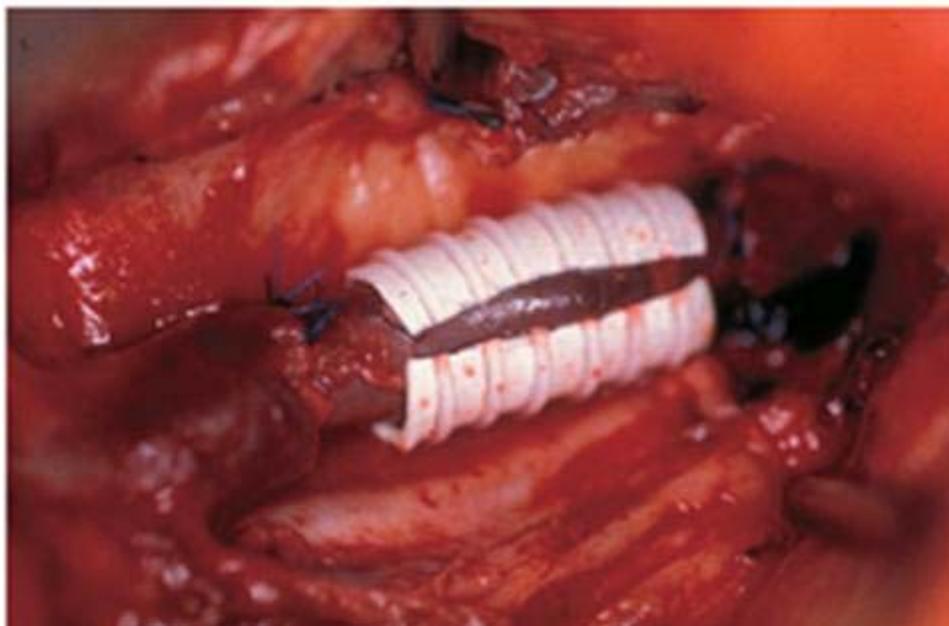

Fig. 15.

In a subset of PTS patients both the femoral and profunda femoral veins are severely post-thrombotic with destroyed valve structures. The femoral confluence can be repaired with individual axillary vein transfers or by en bloc transfer of basilic-brachial confluence provided valves are present and size match requirements are satisfied (see Figure 16).

Fig.16.

LYMPHEDEMA

Background

Lymphedema is an abnormal collection of protein-rich fluid in the interstitium due to a defect in the lymphatic drainage network. Lymphedema most commonly affects the extremities, but it can involve the face, genitalia, or trunk. Numerous causes, both primary and secondary in nature, have been identified for this condition.

The primary causes are due to abnormalities in the lymphatic system that are present at birth, although not always clinically evident until later in life. The 3 primary categories of lymphedema (due to genetic factors) are congenital lymphedema (Milroy disease), lymphedema praecox (Meige disease), and lymphedema tarda. Primary lymphedema can also be associated with various cutaneous syndromes.

Secondary lymphedema is due to an acquired obstruction or infiltration of the lymphatic system. Secondary lymphedema has a number of causes, which include malignancy, infection, obesity, trauma, congestive heart failure, portal hypertension, and therapeutic intervention. Despite the fact that the underlying etiologies of secondary lymphedema vary, clinical progression is similar and difficult to control.

Lymphedema is a progressive, deforming condition that is both physically and psychologically debilitating.

Angiosarcoma arising in an area of long-standing lymphedema is termed Stewart-Treves syndrome. Most cases of Stewart-Treves syndrome occur in the arm after surgery for breast cancer; however, sometimes angiosarcomas can arise in a chronically lymphedematous leg.

Lymphedema is a notoriously debilitating progressive condition with no known cure. The unfortunate patient faces a lifelong struggle of medical, and sometimes surgical, treatment fraught with potentially lethal complications.

The underlying problem is lymphatic dysfunction, resulting in an abnormal accumulation of interstitial fluid containing high molecular weight proteins. This condition underscores the tremendous importance of a normally functioning lymphatic system, which returns proteins, lipids, and accompanying water from the interstitium to the venous circulation near the subclavian vein–internal jugular vein junction, bilaterally. The normal and abnormal flow of

interstitial fluid through the lymphatic system are demonstrated below.

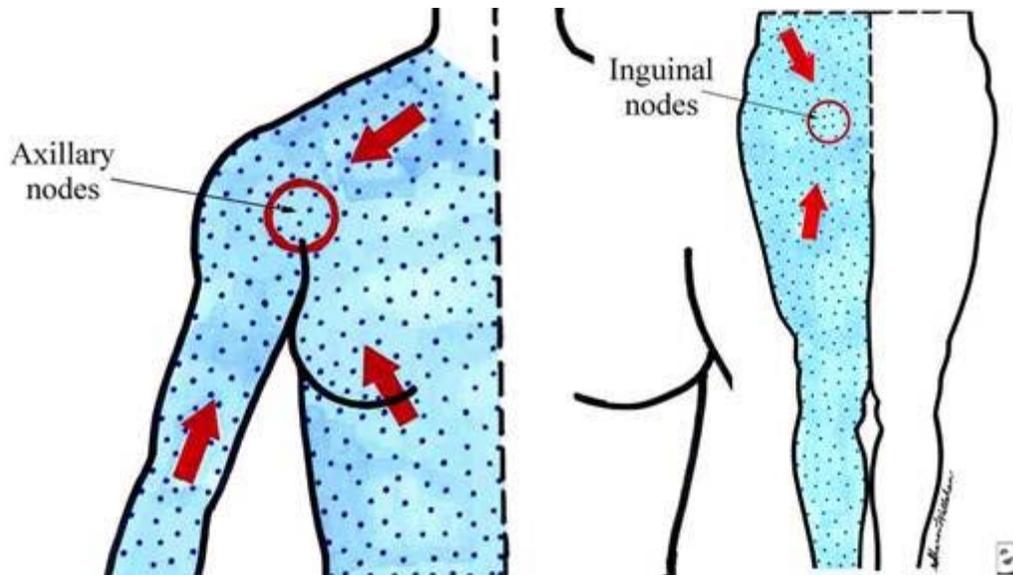

Fig. 17. The body quadrants of superficial lymph drainage

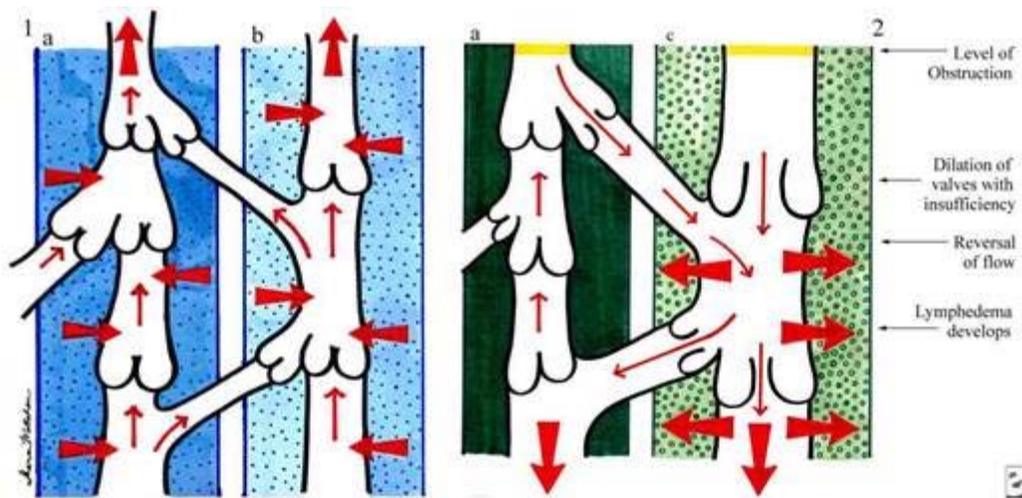

Fig. 18. (1) Normal lymphatic flow in (a) deep systems and (b) superficial systems. Note the small collateral vessels interconnecting the 2 systems. (2) Lymphedema develops from obstruction, dilation of valves, valvular insufficiency, and subsequent reversal of lymphatic flow.

Pathophysiology

The normal function of the lymphatics is to return proteins, lipids, and water from the interstitium to the intravascular space; 40-50% of serum proteins are transported by this route

each day. High hydrostatic pressures in arterial capillaries force proteinaceous fluid into the interstitium, resulting in increased interstitial oncotic pressure that draws in additional water.

Interstitial fluid normally contributes to the nourishment of tissues. About 90% of the fluid returns to the circulation via entry into venous capillaries. The remaining 10% is composed of high molecular weight proteins and their oncotically associated water, which are too large to readily pass through venous capillary walls. This leads to flow into the lymphatic capillaries where pressures are typically subatmospheric and can accommodate the large size of the proteins and their accompanying water. The proteins then travel as lymph through numerous filtering lymph nodes on their way to join the venous circulation.

In a diseased state, the lymphatic transport capacity is reduced. This causes the normal volume of interstitial fluid formation to exceed the rate of lymphatic return, resulting in the stagnation of high molecular weight proteins in the interstitium. It usually occurs after flow has been reduced by 80% or more. The result, as compared to other forms of edema that have much lower concentrations of protein, is high-protein edema, or lymphedema, with protein concentrations of 1.0-5.5 g/mL. This high oncotic pressure in the interstitium favors the accumulation of additional water.

Accumulation of interstitial fluid leads to massive dilatation of the remaining outflow tracts and valvular incompetence that causes reversal of flow from subcutaneous tissues into the dermal plexus. The lymphatic walls undergo fibrosis, and fibrinoid thrombi accumulate within the lumen, obliterating much of the remaining lymph channels. Spontaneous lymphovenous shunts may form. Lymph nodes harden and shrink, losing their normal architecture.

In the interstitium, protein and fluid accumulation initiates a marked inflammatory reaction. Macrophage activity is increased, resulting in destruction of elastic fibers and production of fibrosclerotic tissue. Fibroblasts migrate into the interstitium and deposit collagen. The result of this inflammatory reaction is a change from the initial pitting edema to the brawny nonpitting edema characteristic of lymphedema. Consequently, local immunologic surveillance is suppressed, and chronic infections, as well as malignant degeneration to lymphangiosarcoma, may occur.

The overlying skin becomes thickened and displays the typical *peau d'orange* (orange skin) appearance of congested dermal lymphatics. The epidermis forms thick scaly deposits of keratinized debris and may display a warty verrucosis. Cracks and furrows often develop and accommodate debris and bacteria, leading to lymphorrhea, the leakage of lymph onto the surface of the skin.

Frequency

United States

A common cause of lymphedema reported in the United States is surgical therapeutic intervention (postsurgical complication), most commonly following mastectomy with axillary dissection and radiation therapy for breast cancer. Although not reported as often as postmastectomy induced–lymphedema, obesity is one of the most common causes of lymphedema seen in practice today.

Among the primary causes of lymphedema, lymphedema praecox is the most commonly reported.

International

Worldwide, the most common cause of lymphedema is filariasis infection. More than 100 million people are affected in endemic areas worldwide

Mortality/Morbidity

The outcome for persons with lymphedema depends on its chronicity, the complications that result, and the underlying disease state that caused the lymphedema.

The development of angiosarcoma (ie, Stewart-Treves syndrome) in the setting of lymphedema is the most serious complication of secondary lymphedema. The mean survival rate, after treatment, is approximately 24 months. The 5-year survival rate is 10%.

Other complications that increase morbidity are the development of recurrent cellulitis, bacterial or fungal infections, and lymphangioadenitis.

Sex

Primary lymphedema is most common in females. Lymphedema praecox is the most common form and affects 1 in 100,000 girls and 1 in 400,000 boys.

Age

Secondary lymphedema can affect persons of any age group, and its onset is determined by the primary cause. Hereditary (primary) lymphedema can be divided into 3 groups based on the age of onset of clinical lymphedema, as follows.

- Milroy disease is the familial form of lymphedema that usually manifests from birth to age 1 year.
- Lymphedema praecox (ie, Meige disease) occurs from age 1-35 years. It most commonly occurs around menarche.
- Lymphedema tarda manifests after age 35 years

CLINICAL

History

Patients often report that chronic swelling of an extremity preceded lymphedema. Eighty percent of patients present with lower extremity involvement, although the upper extremities, face, genitalia, and trunk can also be involved. The history confirms involvement of a distal extremity initially, with proximal involvement following. Patients with lymphedema often report painless swelling and leg heaviness.

Fevers, chills, and generalized weakness may be reported. Patients may have a history of recurrent episodes of cellulitis, lymphangitis, fissuring, ulcerations, and/or verrucous changes. Patients have a higher prevalence of bacterial and fungal infections.

In primary lymphedema, patients have a congenital defect in the lymphatic system; therefore, the history of onset is more typical of the specific type.

Also more common is for primary lymphedema to be associated with other anomalies and genetic disorders, such as yellow nail syndrome, Turner syndrome, Noonan syndrome, xanthomatosis,² hemangiomas, neurofibromatosis type 1, distichiasis lymphedema,^{3,4} Klinefelter syndrome, congenital absence of nails, trisomy 21, trisomy 13, and trisomy 18.

A rare inherited disorder, distichiasis-lymphedema syndrome, is characterized by the presence of extra eyelashes (distichiasis) and swelling of the arms and legs (lymphedema). Swelling of the legs, especially below the knees, and eye irritation are common in people with

this disorder. Spinal cysts (epidural) with or without other abnormalities of the spinal column can accompany distichiasis lymphedema. Distichiasis-lymphedema syndrome is inherited as an autosomal dominant genetic trait due to a mutation of the FOX2 gene.

In secondary lymphedema, the associated history should be more evident, based on the primary etiology.

If due to filariasis, the history should include travel or habitation in an endemic area.

Other patients should have a clear history of a neoplasm obstructing the lymphatic system, recurrent episodes of lymphangitis and/or cellulitis, obesity, trauma, or lymphedema resulting after surgery and/or radiation therapy.

A recent history of varicose vein surgery also is reported.

In 2009, Lu et al noted 24 cases of localized lymphedema presenting as solitary large polyps, solid or papillomatous plaques, pedunculated edematous lesions, or tumors that imitated sarcoma. Lesions most commonly occurred on the vulva.

Physical

The earliest symptom of lymphedema is nontender pitting edema of the affected area, most commonly the distal extremities. The face, trunk, and genitalia also may be involved. Radial enlargement of the area occurs over time, which progresses to a nonpitting edema resulting from the development of fibrosis in the subcutaneous fat.

The distal extremities are involved initially, followed by proximal advancement.

Patients have erythema of the affected area and thickening of the skin, which appears as peau d'orange skin and woody edema.

With long-term involvement, ENV develops, which is an area of cobble-stoned, hyperkeratotic, papillomatous plaques most commonly seen on the shins. The plaques of ENV can be covered with a loosely adherent crust, can be weepy or oozing a clear or yellow fluid, and/or can have a foul-smelling odor. The changes of ENV have been described as cobblestone, pebbly, hyperkeratotic, papillomatous, and verrucous.

Fissuring, ulcerations, skin breakdown, and lymphorrhea can also be seen. Lymphorrhea involves the weeping or oozing of clear, yellow, or straw-colored fluids. Superinfection is common and can manifest as impetigo with yellow crusts.

Four cases of cutaneous verruciform xanthomas in association with lymphedema have been cited in the literature. More recent reports have suggested that verruciform xanthomas may be a rare reactive phenomenon found in persons with common cutaneous conditions. Because

verruciform xanthoma is considered by some authorities to be a reactive condition, the link between these 2 entities remains unclear at this time.

A positive Stemmer sign (inability to pinch the dorsal aspect of skin between the first and second toes) may be elicited upon examination.

Other associated physical findings specific for the cause of secondary lymphedema and genetic disorders involving lymphedema may be noted upon examination.

Causes

Both primary and secondary lymphedema can have many causes.

Primary lymphedema

Primary lymphedema is divided into 3 main types, which are distinguished by their age of onset. All are caused by a congenital abnormality in the lymphatic system, although these defects may not always be clinically evident until later in life. Additionally, primary lymphedema also can be associated with other cutaneous and genetic disorders not among the 3 main age-based categories.

Congenital lymphedema, also known as Milroy disease, is an autosomal dominant familial disorder of the lymphatic system that manifests at birth to age 1 year. It is often due to anaplastic lymphatic channels. The lower extremity edema is most commonly bilateral, pitting, and nonpainful. This condition may be linked to a mutation that inactivates VEGFR3. It has been associated with cellulitis, prominent veins, intestinal lymphangiectasias, upturned toenails, and hydrocele.

Lymphedema praecox, also known as Meige disease, is the most common form of primary lymphedema. Seventy percent of cases are unilateral, with lower extremity swelling being more common. This type of primary edema is most often due to hypoplastic lymphatic channels. This condition most often manifests clinically around menarche, suggesting that estrogen may play a role in its pathogenesis.

Lymphedema tarda manifests later in life, usually in persons older than 35 years. It is thought to be due to a defect in the lymphatic valves, resulting in incompetent valve function. Whether this defect is congenital or acquired is difficult to determine.

As mentioned, primary lymphedema is also seen in association with other cutaneous and

genetic disorders.

Lymphedema-distichiasis syndrome is a form of hereditary early- and late-onset lymphedema associated with distichiasis (double row of eyelashes). Affected persons usually manifest bilateral lower extremity lymphedema by age 8-30 years. Lymphatic vessels are usually larger in affected areas. It is a hereditary condition with an autosomal dominant pattern with variable penetrance. It reportedly is associated with a mutation in FOXC2 transcription factor.⁵ Other associated anomalies may include vertebral abnormalities, spinal arachnoid cysts, hemangiomas, cleft palate, ptosis, short stature, webbed neck, strabismus, thoracic duct abnormalities, and microphthalmia.

Primary lymphedema has also been associated with yellow nail syndrome. This entity may be associated with recurrent pleural effusions and bronchiectasis.

Other genetic syndromes and cutaneous conditions associated with primary lymphedema are Turner syndrome, Noonan syndrome, Klinefelter syndrome, neurofibromatosis type 1, hemangiomas, xanthomatosis, and congenital absence of nails. One reported case described lymphedema in association with CHARGE (coloboma, heart anomalies, choanal atresia, somatic and mental retardation, genitourinary anomalies, ear abnormalities) syndrome.

Secondary lymphedema

Secondary Lymphedema is caused by an acquired defect in the lymphatic system and is commonly associated with obesity, infection, neoplasm, trauma, or therapeutic modalities.

The most common cause of secondary lymphedema worldwide is filariasis. This is due to a mosquito-borne nematode infection with the parasite *Wucheria bancrofti*. It commonly occurs in developing countries around the world. This infection results in permanent lymphedema of the limb.

In the developed world, the most common cause of secondary lymphedema is malignancy and treatment.

- It can result from obstruction from metastatic cancer or primary lymphoma or can be secondary to radical lymph node dissection and excision. Although lymphatics are thought to regenerate after transection via surgery, when combined with radiotherapy to the area, the risk of lymphedema increases because of scarring and fibrosis of the tissue.

- The most commonly affected area is the axillary region after mastectomy and radical dissection for breast cancer. Lymphedema can also be seen after regional dissection of pelvic,

para-aortic, and neck lymph nodes.

- Other associated neoplastic diseases are Hodgkin lymphoma, metastatic prostate cancer, cervical cancer, breast cancer, and melanoma.

Morbid obesity frequently causes impairment of lymphatic return and commonly results in lymphedema, as shown in the image below.

Fig. 19. Morbidly obese patient with lymphedema.

- Lymphedema is also associated with trauma, varicose vein surgery, congestive heart failure, portal hypertension, and extrinsic pressure, as shown in the image below.

Fig. 20. Lymphedema in a patient with hypertension, diabetes, and impaired cardiac function

- Recurrent episodes of cellulitis or streptococcal lymphangitis have been linked to the development of lymphedema.

Laboratory Studies

Analysis of blood, urine, or tissue is not needed to make the diagnosis of lymphedema. Such tests, however, help to define the underlying causes of lower extremity edema when the etiology is unclear.

- Liver function, BUN/creatinine levels, and urinalysis results should be checked if a renal or hepatic etiology is suspected.

- Specific markers should be checked if a neoplasm is suspected.

- CBC count with differential should be checked if an infectious etiology is being considered.

Imaging Studies

Imaging is not necessary to make the diagnosis, but it can be used to confirm it, to assess the extent of involvement, and to determine therapeutic intervention.

- Lymphangiography is an invasive technique that can be used to evaluate the lymphatic system and its patency. Although it was once thought to be the first-line imaging modality for lymphedema, it is now rarely used because of the potential adverse effects.

- Lymphoscintigraphy is the new criterion standard to assess the lymphatic system. It allows for detailed visualization of the lymphatic channels with minimal risk. The anatomy and the obstructed areas of lymphatic flow can be assessed.

- Ultrasonography can be used to evaluate the lymphatic and venous systems. Volumetric and structural changes are identified within the lymphatic system. Venous abnormalities such as deep vein thrombosis can be excluded based on ultrasonography findings.

- MRI and CT scanning can also be used to evaluate lymphedema. These radiologic tests can be helpful in confirming the diagnosis and monitoring the effects of treatment. They are also recommended when malignancy is suspected.

Other Tests

A biopsy should be performed if the diagnosis is not clinically apparent, if areas of chronic lymphedema look suspicious, or if areas of chronic ulceration exist.

Histologic Findings

Histologic findings include hyperkeratosis with areas of parakeratosis, acanthosis, and diffuse dermal edema with dilated lymphatic spaces. In chronic lymphedema, marked fibrosis and scattered foci of inflammatory infiltrate can be seen.

Medical Care

The goal of therapy is to restore function, to reduce physical and psychologic suffering, and to prevent the development of infection.

- The first-line treatment is complex physical therapy. This therapy is aimed at improving lymphedema with manual lymphatic drainage, massage, and exercise. It advocates the use of compression stockings (at a minimum of 40 mm Hg), multilayer bandaging, or pneumatic pumps. Leg elevation is essential. Appropriate skin care and debridement is also stressed to prevent recurrent cellulitis or lymphangitis.
- In secondary lymphedema, the underlying etiology (ie, neoplasm, infection) should also be properly treated to relieve the lymphatic obstruction and to improve lymphedema.

- In cases of recurrent cellulitis or lymphangitis, long-term antibiotic therapy with agents such as penicillins or cephalosporins is sometimes used.
- Filariasis has been treated with diethylcarbamazine and albendazole.
- In cases associated with obesity, weight loss is strongly recommended.
- A few pharmacological therapies have been found to be effective in the treatment of lymphedema.
 - The benzopyrones (including coumarin and flavonoids) are a group of drugs that have been found to be successful in treating lymphedema when combined with complex physical therapy. They aid in decreasing excess edematous fluid, softening the limb, decreasing skin temperature, and decreasing the number of secondary infections. The benzopyrones successfully increase the number of macrophages, leading to proteolysis and protein reabsorption. Of note, however, is that hepatotoxicity has been associated with coumarin therapy.
 - Case reports have suggested effective treatment of chronic lymphedematous changes (eg, elephantiasis nostra verrucosa [ENV]) with oral and topical retinoids. These therapies are thought to help normalize keratinization and decrease inflammatory and fibrotic changes.
 - Topical emollients and keratolytics, such as ammonium lactate, urea, and salicylic acid, have been recommended to improve secondary epidermal changes.
 - Diuretics are not effective in treating lymphedema.

Surgical treatment is palliative, not curative, and it does not obviate the need for continued medical therapy. Moreover, it is rarely indicated as the primary treatment modality. Rather, reserve surgical treatment for those who do not improve with conservative measures or in cases where the extremity is so large that it impairs daily activities and prevents successful conservative management.

Medication

Retinoids

These therapies are thought to help normalize keratinization and decrease inflammatory and fibrotic changes.

Acitretin (Soriatane)

Metabolite of etretinate and related to both retinoic acid and retinol (vitamin A). Mechanism of action unknown; however, thought to exert therapeutic effect by modulating keratinocyte differentiation, keratinocyte hyperproliferation, and tissue infiltration by inflammatory cells.

Tazarotene, topical (Tazorac)

Topical gel 0.1%. Retinoid prodrug whose active metabolite modulates differentiation and proliferation of epithelial tissue; may also have anti-inflammatory and immunomodulatory properties. Ensure skin is dry before applying gel

Anthelmintics

Filaria can cause lymphedema by obstruction.

Albendazole (Albenza, Valbazen)

A benzimidazole carbamate drug that inhibits tubulin polymerization, resulting in degeneration of cytoplasmic microtubules. Decreases ATP production in worm, causing energy depletion, immobilization, and, finally, death. Converted in the liver to its primary metabolite, albendazole sulfoxide. Less than 1% of the primary metabolite excreted in urine. Plasma level is noted to rise significantly (as much as 5-fold) when ingested after high-fat meal. Experience with patients <6 y limited. To avoid inflammatory response in CNS, patient must also be started on anticonvulsants and high-dose glucocorticoids.

Emollients/keratolytics

Ammonium lactate lotion (AmLactin, AmLactin XL, Lac-Hydrin)

Alpha-hydroxy acid; normal constituent of tissues and blood. Believed to act as humectant when applied to skin. This may influence hydration of the stratum corneum. In addition, when applied to skin, may act to decrease corneocyte cohesion. The mechanism by which this is accomplished is not yet known. Used to decrease scaling and pruritus. Found in a variety of topical emollient lotions. Ammonium lactate 5% lotion is available over the counter, and lactic acid 12% cream and lotion are available by prescription.

Urea, topical (Carmol, Keralac, Ureacin)

Promotes hydration and removal of excess keratin in conditions of hyperkeratosis

Indications

Surgical treatment is palliative, not curative, and it does not obviate the need for continued medical therapy. Moreover, it is rarely indicated as the primary treatment modality. Rather, reserve surgical treatment for those who do not improve with conservative measures or in cases where the extremity is so large that it impairs daily activities and prevents successful conservative management.

Relevant Anatomy

Before embarking on the treatment of lymphedema, a thorough knowledge of the relevant anatomy is essential. Blind-ended lymphatic capillaries arise within the interstitial spaces of the dermal papillae. These unvalved superficial dermal lymphatics drain into interconnected subdermal channels, which parallel the superficial venous system. These subsequently drain into the deeper, epifascial system of valved trunks lined with smooth muscle cells and located just above the deep fascia of the extremity. This system is responsible for the drainage of lymph from the skin and subcutaneous tissues. Valves provide for unidirectional flow towards regional lymph nodes and eventually the venous circulation in the neck. Flow is achieved by variations of tissue pressure through skeletal muscle contractions, pulsatile blood flow, and contractions of the spiral smooth muscle fibers surrounding larger lymphatic channels.

A deeper valved subfascial system of lymphatics is responsible for the drainage of lymph from the fascia, muscles, joints, ligaments, periosteum, and bone. This subfascial system parallels the deep venous system of the extremity. The epifascial and subfascial systems normally function independently, although valved connections do exist in the popliteal, inguinal, antecubital, and axillary regions where lymph nodes form interconnected chains. These connections probably do not function under normal conditions; however, in lymphedema, some reversed flow through perforators from the epifascial to the subfascial system may occur as a mechanism of decompression of the epifascial system. In lymphedema, the derangement is almost always exclusive to the epifascial lymphatic system, with the

subfascial system being uninvolved. This is the basis for the surgical approaches to lymphedema, which focus on the epifascial system.

Contraindications

Contraindications to intermittent pneumatic pump compression therapy include congestive heart failure, deep vein thrombosis, and active infection.

Surgical Therapy

Surgical treatment is palliative, not curative, and it does not obviate the need for continued medical therapy. Moreover, it is rarely indicated as the primary treatment modality. Rather, reserve surgical treatment for those who do not improve with conservative measures or in cases where the extremity is so large that it impairs daily activities and prevents successful conservative management. The goals of surgical therapy are volume reduction to improve function, facilitation of conservative therapy, and prevention of complications. A myriad of surgical procedures have been advocated, reflecting a lack of clear superiority of one procedure over the others. In general, surgical procedures are classified as physiologic or excisional.

Physiologic procedures attempt to improve lymphatic drainage. Multiple techniques have been described, including omental transposition, buried dermal flaps, enteromesenteric bridging, lymphangioplasty, and microvascular lympholymphatic or lymphovenous anastomoses.⁸ None of these techniques has clearly documented favorable long-term results. Further evaluation is necessary. Moreover, many of these physiologic techniques also include an excisional component, making it difficult to distinguish between the 2 approaches.

Excisional techniques remove the affected tissues, thus reducing the lymphedema load. Some authors advocate suction-assisted removal of subcutaneous tissues, but this technique is difficult because of the extensive subcutaneous fibrosis that is present. Additionally, this approach does not reduce the skin envelope, and the lymphedema often rapidly recurs. Suction-assisted removal of subcutaneous tissue followed by excision of the excess skin envelope has no clear advantage over direct excisional techniques alone.

The Charles procedure is another quite radical excisional technique. This procedure involves the total excision of all skin and subcutaneous tissue from the affected extremity. The underlying fascia is then grafted, using the skin that has been excised. This technique is extreme and is reserved for only the most severe cases. Complications include ulceration,

hyperkeratosis, keloid formation, hyperpigmentation, weeping dermatitis, and severe cosmetic deformity.

Van der Walt et al developed a modified Charles procedure in which negative-pressure dressing was employed following debulking surgery, with skin grafting delayed for 5-7 days.⁹ In a report on 8 patients suffering from severe primary lymphedema who underwent the procedure, the authors reported that the patients experienced no major complications. Minor complications, including operative blood loss and, in 3 patients, the need for additional grafting, did occur.

Staged excision has become the option of choice for many authors. This procedure involves removing only a portion of skin and subcutaneous tissue, followed by primary closure. After approximately 3 months, the procedure is repeated on a different area of the extremity. This procedure is safe, reliable, and demonstrates the most consistent improvement with the lowest incidence of complications.

Preoperative Details

Prior to surgery, appropriate documentation is necessary to evaluate the outcome of treatment. This includes photographic documentation as well as extremity measurements. Ideally, these measurements are of limb volume by water displacement, although some rely on circumferential measurements alone. Obtain measurements and photographs at the same time of day each time, document affected extremities and contralateral extremities, and preferably conduct documentation in the morning after extremity elevation in bed overnight.

Institute strict elevation and pneumatic compression, if available, 24-72 hours prior to surgery. This allows maximum excision to be performed. The extremity must also be free of infection at the time of surgery, and a single dose of preoperative intravenous antibiotic is administered.

Intraoperative Details

After the establishment of appropriate anesthesia, the operative field is sterilized and draped according to surgeon preference.

A pneumatic tourniquet is placed at the root of the extremity and insufflated after the extremity has been exsanguinated.

A longitudinal incision is made along the entire extremity, and skin flaps, 1.0-1.5 cm

thick, are elevated.

Subcutaneous tissue is then excised, taking care not to injure peripheral sensory nerves.

Some authors also excise a strip of deep fascia, but this should not be performed around joints because it may cause instability.

Once the subcutaneous excision is complete, redundant skin is resected. Often, a strip that is 5-10 cm wide may be removed.

The wound is closed over suction drains.

Postoperative Details

Postoperatively, the extremity is immobilized in a splint and elevated while the patient is placed on strict bed rest.

Antibiotics may be continued until drain removal, according to surgeon preference.

Drains are typically removed at 5-7 days postoperatively, as dictated by a decrease in drain output.

Sutures are removed at 10-14 days and replaced by Steri-Strips.

Measure the patient for a new compression garment when the new dimensions of the extremity have stabilized.

After approximately 10 days, the patient may gradually begin dependency on the extremity with compression bandages or an elastic garment in place.

Follow-up

Once discharged from the hospital, the patient should be seen regularly in the outpatient clinic.

Patients must wear compression garments for 4-6 weeks continuously, and dependency on the involved extremity may be gradually increased at the discretion of the treating physician.

Once healed to physician satisfaction, the patient may return to a normal routine of elevation at night and compression garment therapy during the day.

Follow-up visits should include documentation of circumferential measurement or water displacement of the affected and contralateral extremities as well as photographic documentation.

When staging procedures, allow approximately 3 months between procedures to allow complete healing of the initial operative site.

Complications

Patients with chronic lymphedema for 10 years have a 10% risk of developing lymphangiosarcoma, the most dreaded complication of this disease. Patients with this tumor commonly present with a reddish purple discoloration or nodule that tends to form satellite lesions. It may be confused with Kaposi sarcoma or traumatic ecchymosis. This tumor is highly aggressive, requires radical amputation of the involved extremity, and has a very poor prognosis. The 5-year survival rate is less than 10%, and the average survival following diagnosis is 19 months. This malignant degeneration is most commonly observed in patients with postmastectomy lymphedema (Stewart-Treves syndrome), where incidence is estimated to be 0.5%.

Other complications of lymphedema include recurrent bouts of cellulitis and/or lymphangitis, deep venous thrombosis, severe functional impairment, cosmetic embarrassment, and necessary amputation. Complications following surgery are common and include partial wound separation, seroma, hematoma, skin necrosis, and exacerbation of foot or hand edema.

Outcome and Prognosis

At present, no cure for lymphedema exists. Surgery is palliative at best, and it may be a part of the lifelong therapy patients must endure to manage this disease.

Future and Controversies

A myriad of surgical procedures have been advocated, reflecting a lack of clear superiority of one procedure over the others. Multiple physiological and excisional techniques have been described. None of the physiological techniques has clearly documented favorable long-term results; further evaluation is necessary. Moreover, many of the physiologic techniques also include an excisional component, making it difficult to distinguish between the 2 approaches.

DEEP VEIN THROMBOSIS

Introduction of acute deep venous thrombosis

Deep venous thrombosis (DVT) most commonly involves the deep veins of the leg or arm, often resulting in potentially life-threatening emboli to the lungs or debilitating venous alular dysfunction and chronic leg swelling. Deep venous thrombosis (DVT) is also one of the most prevalent medical problems today, with an annual incidence of 117 cases per 100,000. Each year in the United States, more than 200,000 people develop venous thrombosis; of those, 50,000 cases are complicated by pulmonary embolism.¹ Early recognition and appropriate treatment of deep venous thrombosis (DVT) and its complications can save many lives.

Pathophysiology

Over a century ago, Rudolf Virchow described 3 factors that are critically important in the development of venous thrombosis: (1) venous stasis, (2) activation of blood coagulation, and (3) vein damage. Over time, refinements have been made in their description and importance to the development of venous thrombosis. The origin of venous thrombosis is frequently multifactorial, with components of the triad of variable importance in individual patients.

Studies have shown that low flow sites, such as the soleal sinuses, behind venous valve pockets, and at venous confluences, are at most risk for the development of venous thrombi. However, stasis alone is not enough to facilitate the development of venous thrombosis. Experimental ligation of rabbit jugular veins for periods of up to 60 minutes have failed to consistently cause venous thrombosis. Although, patients that are immobilized for long periods of time seem to be at high risk for the development of venous thrombosis, an additional stimulus is required to develop deep venous thrombosis (DVTs).

Mechanical injury to the vein wall appears to provide an added stimulus for venous thrombosis. Hip arthroplasty patients with the associated femoral vein manipulation represent a high-risk group that cannot be explained by just immobilization, with 57% of thrombi originating in the affected femoral vein rather than the usual site of stasis in the calf.⁶ Endothelial injury can convert the normally antithrombogenic endothelium to become prothrombotic by stimulating the production of tissue factor, von Willebrand factor, and fibronectin.

Genetic mutations within the blood's coagulation cascade represent those at highest risk for the development of venous thrombosis (See Table 1).

Table 1. Relative Risk for Venous Thrombosis

Thrombophilic Defect	Relative Risk
Antithrombin deficiency	8-10
Protein C deficiency	7-10
Protein S deficiency	8-10
Factor V Leiden	3-7
Hyperhomocysteinemia	2.5
Anticardiolipin antibodies	3.2

Primary deficiencies of coagulation inhibitors antithrombin, protein C, and protein S are associated with 5-10% of all thrombotic events. Resistance of procoagulant factors to an intact anticoagulation system has also recently been described with the recognition of factor V Leiden mutation, representing 10-65% of patients with deep venous thrombosis (DVT).⁸ In the setting of venous stasis, these factors are allowed to accumulate in thrombosis prone sites, where mechanical vessel injury has occurred, stimulating the endothelium to become prothrombotic.

Components of the Virchow triad are of variable importance in individual patients, but the end result is early thrombus interaction with the endothelium. This interaction stimulates local cytokine production and facilitates leukocyte adhesion to the endothelium, both of which promote venous thrombosis. Depending on the relative balance between activated coagulation and thrombolysis, thrombus propagation occurs.

Over time, thrombus organization begins with the infiltration of inflammatory cells into the clot. This results in a fibroelastic intimal thickening at the site of thrombus attachment in most patients and a fibrous synechia in up to 11%. In many patients, this interaction between vessel wall and thrombus leads to alular dysfunction and overall vein wall fibrosis. Histological examination of vein wall remodeling after venous thrombosis has demonstrated an imbalance in connective tissue matrix regulation and a loss of regulatory venous contractility that contributes to the development of chronic venous insufficiency.

Risk factors

Many factors have been identified as known risk factors for the development of venous thrombosis. The single most powerful risk marker remains a prior history of DVT with up to 25% of acute venous thrombosis occurring in such patients. Pathologically, remnants of previous thrombi are often seen within the specimens of new acute thrombi. However, recurrent thrombosis may actually be the result of primary hypercoagulable states. Abnormalities within the coagulation cascade are the direct result of discrete genetic mutations within the coagulation cascade. Deficiencies of protein C, protein S, or antithrombin III account for approximately 5-10% of all cases of deep venous thrombosis (DVT).

Age has been well studied as an independent risk factor for venous thrombosis development. Although a 30-fold increase in incidence is noted from age 30 to age 80, the effect appears to be multifactorial, with more thrombogenic risk factors occurring in the elderly than in those younger than 40 years. Venous stasis, as seen in immobilized patients and paralyzed limbs, also contributes to the development of venous thrombosis. Autopsy studies parallel the duration of bed rest to the incidence of venous thrombosis, with 15% of patients in those studies dying within 7 days of bedrest to greater than 80% in those dying after 12 weeks.² Within stroke patients, deep venous thrombosis (DVT) is found in 53% of paralyzed limbs, compared with only 7% on the nonaffected side.

Malignancy is noted in up to 30% of patients with venous thrombosis. The thrombogenic mechanisms involve abnormal coagulation, as evidenced by 90% of cancer patients having some abnormal coagulation factors.¹⁸ Chemotherapy may increase the risk of venous thrombosis by affecting the vascular endothelium, coagulation cascades, and tumor cell lysis. The incidence has been shown to increase in those patients undergoing longer courses of therapy for breast cancer, from 4.9% for 12 weeks of treatment to 8.8% for 36 weeks. Additionally, deep venous thrombosis (DVT) complicates 29% of surgical procedures done for malignancy.

Postoperative venous thrombosis varies depending on a multitude of patient factors, including the type of surgery undertaken. Without prophylaxis, general surgery operations typically have an incidence of deep venous thrombosis (DVT) around 20%, while orthopedic hip surgery can occur in up to 50% of patients. Based on radioactive labeled fibrinogen, about half of lower extremity thrombi develop intraoperatively. Perioperative immobilization,

coagulation abnormalities, and venous injury all contribute to the development of surgical venous thrombosis.

Other clinical settings commonly reported as risk factors have also been identified and are shown in Table 2, 3

Table 2. Risk Factors for Venous Thromboembolic Disease

Risk Factor	Odds Ratio
Hospitalization with recent surgery	21.72
Hospitalization without surgery	7.98
Trauma	12.69
Malignancy	6.53
Central venous catheter	5.55
Neurologic disease with paralysis	3.04

Table 3. Risk Factors for Venous Thromboembolism

Acquired	Inherited
Advanced age	Factor V Leiden
Hospitalization/immobilization	Prothrombin 20210A
Hormone replacement therapy and oral contraceptive use	Antithrombin deficiency
	Protein C deficiency
Pregnancy and puerperium	Protein S deficiency
Prior venous thromboembolism	Factor XI elevation
Malignancy	Dysfibrinogenemia
Major surgery	Mixed Etiology
Obesity	Homocysteinemia
Nephrotic syndrome	Factor VII, VIII, IX, XI elevation
Trauma or spinal cord injury	Hyperfibrinogenemia
Long-haul travel (>6 h)	Activated protein C resistance without factor V Leiden
Varicose veins	
Antiphospholipid antibody syndrome	
Myeloproliferative disease	
Polycythemia	

Clinical and diagnostic evaluation

The clinical diagnosis of deep venous thrombosis (DVT) is difficult and fraught with uncertainty. The classic signs and symptoms of deep venous thrombosis (DVT) are those associated with obstruction to venous drainage and include pain, tenderness, and unilateral leg swelling. Other associated nonspecific findings are warmth, erythema, a palpable cord, and pain upon passive dorsiflexion of the foot (Homan sign). However, even with patients with classic symptoms, up to 46% have negative venograms. Furthermore, up to 50% of those with image-documented venous thrombosis lack any specific symptom. Deep venous thrombosis (DVT) simply cannot be diagnosed or excluded based on clinical findings; thus, diagnostic tests must be performed whenever the diagnosis of deep venous thrombosis (DVT) is being considered.

When a patient has deep venous thrombosis (DVT), symptoms may be present or absent, unilateral or bilateral, or mild or severe. Thrombus that does not cause a net venous outflow obstruction is often asymptomatic. Thrombus that involves the iliac bifurcation, the pelvic veins, or the vena cava produces leg edema that is usually bilateral rather than unilateral. High partial obstruction often produces mild bilateral edema that is mistaken for the dependent edema of right-sided heart failure, fluid overload, or hepatic or renal insufficiency.

Severe venous congestion produces a clinical appearance that can be indistinguishable from the appearance of cellulitis. Patients with a warm, swollen, tender leg should be evaluated for both cellulitis and deep venous thrombosis (DVT) because patients with primary deep venous thrombosis (DVT) often develop a secondary cellulitis, while patients with primary cellulitis often develop a secondary deep venous thrombosis (DVT). Superficial thrombophlebitis, likewise, is often associated with a clinically inapparent underlying DVT.

If a patient is thought to have pulmonary embolism (PE) or has documented PE, the absence of tenderness, erythema, edema, or a palpable cord upon examination of the lower extremities does not rule out thrombophlebitis, nor does it imply a source other than a leg vein. More than two thirds of patients with proven PE lack any clinically evident phlebitis. Nearly one third of patients with proven PE have no identifiable source of deep venous thrombosis (DVT), despite a thorough investigation. Autopsy studies suggest that even when the source is

clinically inapparent, it lies undetected within the deep venous system of the lower extremity and pelvis in 90% of cases.

Vascular Lab and Radiologic Evaluation

Duplex Ultrasound

DUS is now the most commonly performed test for the detection of infrainguinal DVT, both above and below the knee, and has a sensitivity and specificity of >95% in symptomatic patients. DUS combines real-time B-mode ultrasound with pulsed Doppler capability. Color flow imaging is useful in more technically difficult examinations, such as in the evaluation of possible calf vein DVT. This combination offers the ability to noninvasively visualize the venous anatomy, detect occluded and partially occluded venous segments, and demonstrate physiologic flow characteristics using a mobile self-contained device.

In the supine patient, normal lower extremity venous flow is phasic (Fig. 1), decreasing with inspiration in response to increased intra-abdominal pressure with the descent of the diaphragm and then increasing with expiration. When the patient is upright, the decrease in intra-abdominal pressure with expiration cannot overcome the hydrostatic column of pressure existing between the right atrium and the calf. Muscular contractions of the calf, along with the one-way venous valves, are then required to promote venous return to the heart. Flow also can be increased by leg elevation or compression and decreased by sudden elevation of intra-abdominal pressure (Valsalva's maneuver). In a venous DUS examination performed with the patient supine, spontaneous flow, variation of flow with respiration, and response of flow to Valsalva's maneuver are all assessed. However, the primary method of detecting DVT with ultrasound is demonstration of the lack of compressibility of the vein with probe pressure on B-mode imaging. Normally, in transverse section, the vein walls should coapt with pressure. Lack of coaptation indicates thrombus.

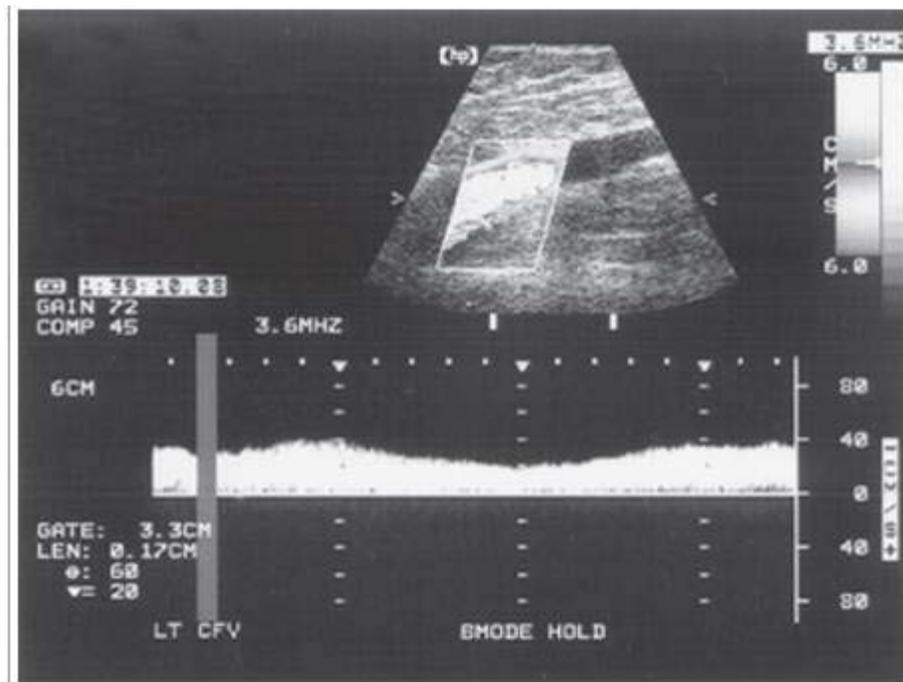

Fig. 1. Duplex ultrasound scan of a normal femoral vein with phasic flow signals.

The examination begins at the ankle and continues proximally to the groin. Each vein is visualized, and the flow signal is assessed with distal and proximal compression. Lower extremity DVT can be diagnosed by any of the following DUS findings: lack of spontaneous flow (Fig. 2), inability to compress the vein (Fig. 3), absence of color filling of the lumen by color flow DUS, loss of respiratory flow variation, and venous distention. Again, lack of venous compression on B-mode imaging is the primary diagnostic variable. Several studies comparing B-mode ultrasound to venography for the detection of femoropopliteal DVT in patients clinically suspected to have DVT report sensitivities of >91% and specificities of >97%. The ability of DUS to assess isolated calf vein DVT varies greatly, with sensitivities ranging from 50 to 93% and specificities approaching 100%.

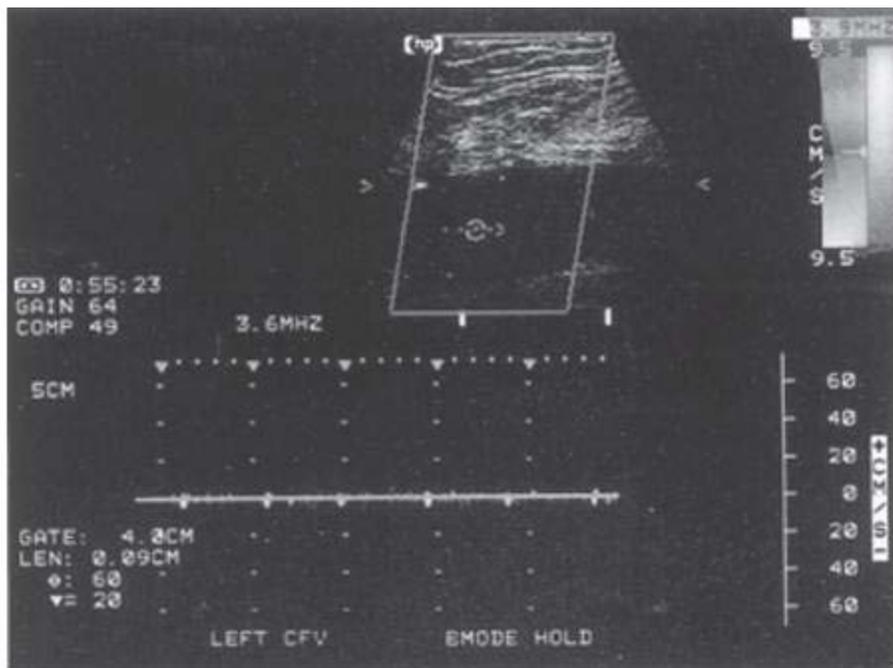

Fig. 2. Duplex ultrasound of a femoral vein containing thrombus demonstrating no flow within the femoral vein

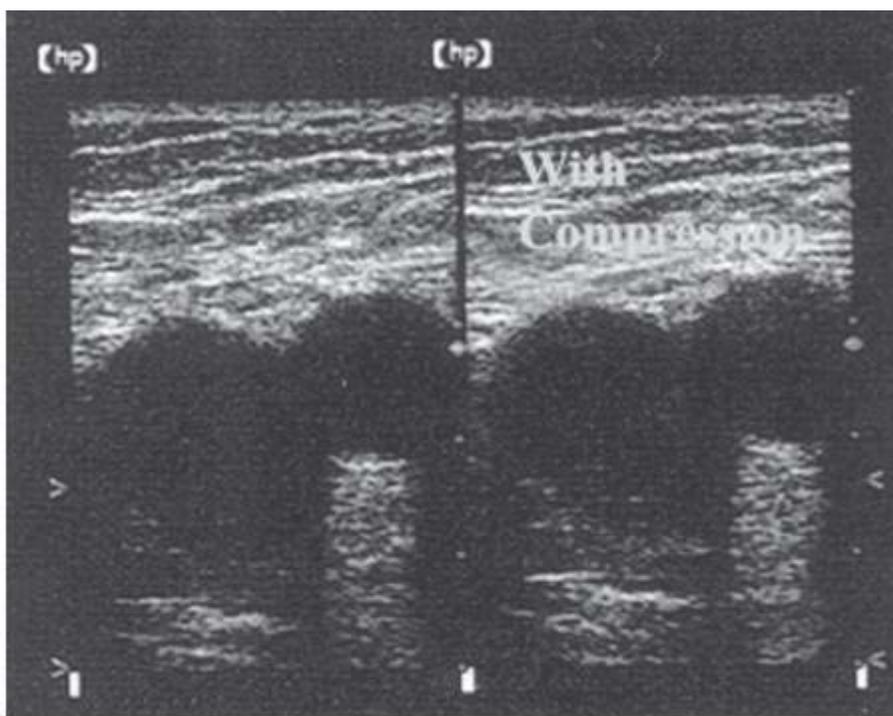

Fig. 3. B-mode ultrasound of the femoral vein in cross-section. The femoral vein does not collapse with external compression

Impedance Plethysmography

Impedance plethysmography (IPG) was the primary noninvasive method of diagnosing DVT before the widespread use of DUS but is infrequently used today. IPG is based on the principle that resistance to the flow of electricity between two electrodes, or electrical impedance, occurs as the volume of the extremity changes in response to blood flow. Two pairs of electrodes containing aluminum strips are placed circumferentially around the leg approximately 10 cm apart and a low-level current is delivered to the two outer electrodes. A pneumatic cuff is inflated over the thigh for venous outflow obstruction and then rapidly deflated. Changes in electrical resistance resulting from lower extremity blood volume changes are quantified. IPG is less accurate than DUS for the detection of proximal DVT, with an 83% sensitivity in symptomatic patients. It is a poor detector of calf vein DVT.

Iodine 125 Fibrinogen Uptake

Iodine 125 fibrinogen uptake (FUT) is a seldom used technique that involves IV administration of radioactive fibrinogen and monitoring for increased uptake in fibrin clots. An increase of 20% or more in one area of a limb indicates an area of thrombus.²³ FUT can detect DVT in the calf, but high background radiation from the pelvis and the urinary tract limits its ability to detect proximal DVT. It also cannot be used in an extremity that has recently undergone surgery or has active inflammation. In a prospective study, FUT had a sensitivity of 73% and specificity of 71% for identification of DVT in a group of symptomatic and asymptomatic patients. Currently, FUT is primarily a research tool of historic interest.

Venography

Venography is the most definitive test for the diagnosis of DVT in both symptomatic and asymptomatic patients. It is the gold standard to which other modalities are compared. This procedure involves placement of a small catheter in the dorsum of the foot and injection of a radiopaque contrast agent. Radiographs are obtained in at least two projections. A positive study result is failure to fill the deep system with passage of the contrast medium into the superficial system or demonstration of discrete filling defects (Fig. 4). A normal study result virtually excludes the presence of DVT. In a study of 160 patients with a normal venogram followed for 3 months, only two patients (1.3%) subsequently developed DVT and no patients

experienced symptoms of PE.

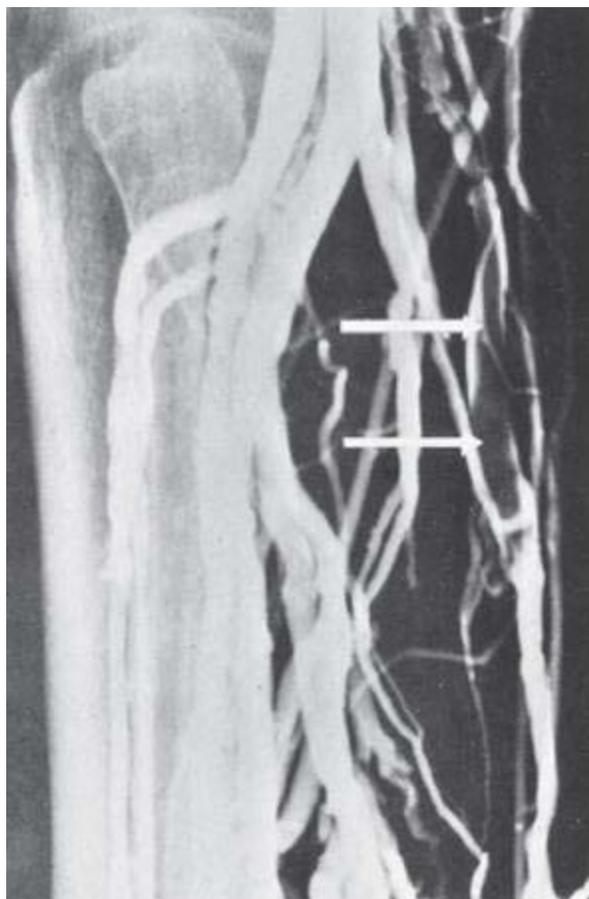

Fig. 4. Venogram showing a filling defect in the popliteal vein (*arrows*).

Venography is not routinely used for the evaluation of lower extremity DVT because of the associated complications discussed previously. Currently, venography is reserved for imaging before operative venous reconstruction and catheter-based therapy. It does, however, remain the procedure of choice in research studies evaluating methods of prophylaxis for DVT.

Laboratory analysis has also been used in aiding the diagnosis of venous thrombosis. D-dimers are degradation products of cross-linked fibrin by plasmin that are detected by diagnostic assays. Although highly sensitive, up to 97%, elevated levels are not specific with rates as low as 35%.²⁷ Many other clinical situations can result in elevated D-dimer levels, including infection, trauma, postoperative states, and malignancy.²⁸ Additional blood work should include coagulation studies to evaluate for a hypercoagulable state, if clinically indicated. A prolonged prothrombin time or activated partial thromboplastin time does not imply a lower risk of new thrombosis. Progression of deep vein thrombosis (DVT) and PE can occur despite full therapeutic anticoagulation in 13% of patients.

Treatment

Once the diagnosis of VTE has been made, antithrombotic therapy should be initiated promptly. If clinical suspicion for VTE is high, it may be prudent to start treatment while the diagnosis is being objectively confirmed. The theoretic goals of VTE treatment are the prevention of mortality and morbidity associated with PE and the prevention of the postphlebotic syndrome. However, the only proven benefit of anticoagulant treatment for DVT is the prevention of death from PE. Treatment regimens may include antithrombotic therapy, vena caval interruption, catheter-directed or systemic thrombolytic therapy, and operative thrombectomy.

Antithrombotic Therapy

Antithrombotic therapy may be initiated with IV or SC unfractionated heparin, SC low molecular weight heparin, or SC fondaparinux (a synthetic pentasaccharide). This initial therapy usually is continued for at least 5 days, while oral vitamin K antagonists are being simultaneously administered. The initial therapy typically is discontinued when the international normalized ratio (INR) is ≥ 2.0 for 24 hours.

Unfractionated heparin (UFH) binds to antithrombin via a specific 18-saccharide sequence, which increases its activity over 1000-fold. This antithrombin-heparin complex primarily inhibits factor IIa (thrombin) and factor Xa and, to a lesser degree, factors IXa, XIa, and XIIa. In addition, UFH also binds to tissue factor pathway inhibitor, which inhibits the conversion of factor X to Xa, and factor IX to IXa. Finally, UFH catalyzes the inhibition of thrombin by heparin cofactor II via a mechanism that is independent of antithrombin.

UFH therapy is most commonly administered with an initial IV bolus of 80 units/kg or 5000 units. Weight-based UFH dosages have been shown to be more effective than standard fixed boluses in rapidly achieving therapeutic levels. The initial bolus is followed by a continuous IV drip, initially at 18 units/kg per hour or 1300 units per hour. The half-life of IV UFH ranges from 45 to 90 minutes and is dose dependent. The level of antithrombotic therapy should be monitored every 6 hours using the activated partial thromboplastin time (aPTT), with the goal range of 1.5 to 2.5 times control values. This should correspond with plasma heparin anti-Xa activity levels of 0.3 to 0.7 IU/mL.

Initial anticoagulation with UFH may be administered SC, although this route is less commonly used. Adjusted-dose therapeutic SC UFH is initiated with 17,500 units, followed by

250 units/kg twice daily, and dosing is adjusted to an aPTT goal range similar to that for IV UFH. Fixed-dose unmonitored SC UFH is started with a bolus of 333 units/kg, followed by 250 units/kg twice daily.

Hemorrhage is the primary complication of UFH therapy. The rate of major hemorrhage (fatal, intracranial, retroperitoneal, or requiring transfusion of >2 units of packed red blood cells) is approximately 5% in hospitalized patients undergoing UFH therapy (1% in medical patients and 8% in surgical patients).²⁷ For patients with UFH-related bleeding complications, cessation of UFH is required, and anticoagulation may be reversed with protamine sulfate. Protamine sulfate binds to UFH and forms an inactive salt compound. Each milligram of protamine neutralizes 90 to 115 units of heparin, and the dosage should not exceed 50 mg IV over any 10-minute period. Side effects of protamine sulfate include hypotension, pulmonary edema, and anaphylaxis. Patients with prior exposure to protamine-containing insulin (NPH) and patients with allergy to fish may have an increased risk of hypersensitivity, although no direct relationship has been established. The protamine infusion should be terminated if any side effects occur.

In addition to hemorrhage, heparin also has unique complications. Heparin-induced thrombocytopenia (HIT) results from heparin-associated antiplatelet antibodies (HAAs) directed against platelet factor 4 complexed with heparin. HIT occurs in 1 to 5% of patients being treated with heparin. In patients with repeat heparin exposure (such as vascular surgery patients), the incidence of HAAs may be as high as 21%. HIT occurs most frequently in the second week of therapy and may lead to disastrous venous or arterial thrombotic complications. Therefore, platelet counts should be monitored periodically in patients receiving continuous heparin therapy. All forms of heparin should be stopped if there is a high clinical suspicion or confirmation of HIT [usually accompanied by an unexplained thrombocytopenia (<100,000/

L) or platelet count decrease of 30 to 50%]. Fortunately, direct thrombin inhibitors (recombinant hirudin, argatroban, bivalirudin) now are available as alternative antithrombotic agents (see later). Another complication of prolonged high-dose heparin therapy is osteopenia, which results from impairment of bone formation and enhancement of bone resorption by heparin.

Low molecular weight heparins (LMWHs) are derived from the depolymerization of porcine UFH. Like UFH, LMWHs bind to antithrombin via a specific pentasaccharide sequence to expose an active site for the neutralization of factor Xa. However, LMWHs lack the sufficient number of additional saccharide units (18 or more), which results in less

inactivation of thrombin (factor IIa). In comparison to UFH, LMWHs have increased bioavailability (>90% after SC injection), longer half-lives (approximately 4 to 6 hours), and more predictable elimination rates. Weight-based once- or twice-daily SC LMWH injections, for which no monitoring is needed, provide a distinct advantage over continuous IV infusions of UFH for treatment of VTE.

Most patients who receive therapeutic LMWH do not require monitoring. Patients who do require monitoring include those with significant renal insufficiency or failure, pediatric patients, obese patients of >120 kg, and patients who are pregnant. Monitoring may be performed using anti-Xa activity assays. However, the therapeutic anti-Xa goal range will depend on the type of LMWH and the frequency of dosing. Numerous LMWHs are commercially available. The various preparations differ in their anti-Xa and anti-IIa activities, and the treatment dosing for one LMWH cannot be extrapolated for use with another. The action of LMWHs may be partially reversed (approximately 60%) with protamine sulfate.

Numerous well-designed trials comparing SC LMWH with IV and SC UFH for the treatment of DVT have been critically evaluated in several meta-analyses. The more recent studies demonstrate a decrease in thrombotic complications, bleeding, and mortality with LMWHs. LMWHs also are associated with a decreased rate of HAAb formation and HIT (<2%) compared with UFH (at least in prophylactic doses). However, patients with established HIT should not subsequently receive LMWHs due to significant rates of cross reactivity. A major benefit of LMWHs is the ability to treat patients with VTE as outpatients. In a randomized study comparing IV UFH and the LMWH nadroparin calcium, there was no significant difference in recurrent thromboembolism (8.6% for UFH vs. 6.9% for LMWH) or major bleeding complications (2.0% for UFH vs. 0.5% for LMWH). There was a 67% reduction in mean days in the hospital for the LMWH group.

A patient with VTE should meet several criteria before receiving outpatient LMWH therapy. First, the patient should not require hospitalization for any associated conditions. The patient should not require monitoring of the LMWH therapy (which is necessary in patients with severe renal insufficiency, pediatric patients, obese patients, and pregnant patients). The patient should be hemodynamically stable with a low suspicion of PE and have a low bleeding risk. An established outpatient system to administer LMWH and warfarin, as well as to monitor for recurrent VTE and bleeding complications, should be present. In addition, the patient's symptoms of pain and edema should be controllable at home.

Fondaparinux currently is the only synthetic pentasaccharide that has been approved by the U.S. Food and Drug Administration (FDA) for the initial treatment of DVT and PE. Its

five-polysaccharide sequence binds and activates antithrombin, causing specific inhibition of factor Xa. In two large noninferiority trials, fondaparinux was compared with the LMWH enoxaparin for the initial treatment of DVT and with IV UFH for the initial treatment of PE. The rates of recurrent VTE ranged from 3.8 to 5%, with rates of major bleeding of 2 to 2.6%, for all treatment arms. The drug is administered SC once daily with a weight-based dosing protocol: 5 mg, 7.5 mg, or 10 mg for patients weighing <50 kg, 50 to 100 kg, or >100 kg, respectively. The half-life of fondaparinux is approximately 17 hours in patients with normal renal function. There are rare case reports of fondaparinux-induced thrombocytopenia.

Direct-thrombin inhibitors (DTIs) include recombinant hirudin, argatroban, and bivalirudin. These antithrombotic agents bind to thrombin, inhibiting the conversion of fibrinogen to fibrin as well as thrombin-induced platelet activation. These actions are independent of antithrombin. The direct thrombin inhibitors should be reserved for (a) patients in whom there is a high clinical suspicion or confirmation of HIT, and (b) patients who have a history of HIT or test positive for heparin-associated antibodies. In patients with established HIT, DTIs should be administered for at least 7 days, or until the platelet count normalizes. Warfarin may then be introduced slowly, overlapping therapy with a DTI for at least 5 days.⁴¹ Because bivalirudin is approved primarily for patients with or without HIT who undergo percutaneous coronary intervention, it is not discussed here in further detail.

Commercially available hirudin is manufactured using recombinant DNA technology. It is indicated for the prophylaxis and treatment of patients with HIT. In patients with normal renal function, recombinant hirudin is administered in an IV bolus dose of 0.4 mg/kg, followed by a continuous IV infusion of 0.15 mg/kg per hour. The half-life ranges from 30 to 60 minutes. The aPTT is monitored, starting approximately 4 hours after initiation of therapy, and dosage is adjusted to maintain an aPTT of 1.5 to 2.5 times the laboratory normal value. The less commonly used ecarin clotting time is an alternative method of monitoring. Because recombinant hirudin is eliminated via renal excretion, significant dosage adjustments are required in patients with renal insufficiency.

Argatroban is indicated for the prophylaxis and treatment of thrombosis in HIT. It also is approved for patients with, or at risk for, HIT who undergo percutaneous coronary intervention. Antithrombotic prophylaxis and therapy are initiated with a continuous IV infusion of 2 g/kg per minute, without the need for a bolus. The half-life ranges from 39 to 51 minutes, and the dosage is adjusted to maintain an aPTT of 1.5 to 3 times normal. Large initial boluses and higher rates of continuous infusion are reserved for patients with coronary artery thrombosis and myocardial infarction. In these patients, therapy is monitored using the activated clotting

time. Argatroban is metabolized by the liver, and the majority is excreted via the biliary tract. Significant dosage adjustments are needed in patients with hepatic impairment. There is no reversal agent for argatroban.

Vitamin K antagonists, which include warfarin and other coumarin derivatives, are the mainstay of long-term antithrombotic therapy in patients with VTE. Warfarin inhibits the γ -carboxylation of vitamin K–dependent procoagulants (factors II, VII, IX, X) and anticoagulants (proteins C and S), which results in the formation of less functional proteins. Warfarin usually requires several days to achieve its full effect, because normal circulating coagulation proteins must first undergo their normal degradation. Factors X and II have the longest half-lives, in the range of 36 and 72 hours, respectively. In addition, the steady-state concentration of warfarin is usually not reached for 4 to 5 days.

Warfarin therapy usually is monitored by measuring the INR, calculated using the following equation:

$$\text{INR} = \left(\frac{\text{patient prothrombin time}}{\text{laboratory normal prothrombin time}} \right)^{\text{ISI}}$$

where *ISI* is the international sensitivity index. The ISI describes the strength of the thromboplastin that is added to activate the extrinsic coagulation pathway. The therapeutic target INR range is usually 2.0 to 3.0, but the response to warfarin is variable and depends on liver function, diet, age, and concomitant medications. In patients receiving anticoagulation therapy without concomitant thrombolysis or venous thrombectomy, the vitamin K antagonist may be started on the same day as the initial parenteral anticoagulant, usually at doses ranging from 5 to 10 mg. Smaller initial doses may be needed in older and malnourished patients, in those with liver disease or congestive heart failure, and in those who have recently undergone major surgery.

The recommended duration of warfarin antithrombotic therapy is increasingly being stratified based on whether the DVT was provoked or unprovoked, whether it was the first or a recurrent episode, where the DVT is located, and whether malignancy is present. Current American College of Chest Physicians (ACCP) recommendations for duration of warfarin therapy are summarized in Table 24-3. In patients with proximal DVT, several randomized clinical trials have demonstrated that shorter-term antithrombotic therapy (4 to 6 weeks) is associated with a higher rate of recurrence than 3 to 6 months of anticoagulation. In these trials, most of the patients with transient risk factors had a low rate of recurrent VTE; most of

the recurrences were in patients with continuing risk factors. These studies support the ACCP recommendation that 3 months of anticoagulation is sufficient to prevent recurrent VTE in patients whose DVT occurred around the time of a transient risk factor (e.g., hospitalization, orthopedic or major general surgery).

Table 4. Summary of American College of Chest Physicians Recommendations Regarding Duration of Long-Term Antithrombotic Therapy for Deep Vein Thrombosis (DVT)

Clinical Subgroup	Antithrombotic Treatment Duration
First episode DVT/transient risk	VKA for 3 mo
First episode DVT/unprovoked	VKA for at least 3 mo
	Consider for long-term therapy if:
	• Proximal DVT
	• Minimal bleeding risk
	• Stable coagulation monitoring
Distal DVT/unprovoked	VKA for 3 mo
Second episode DVT/unprovoked	VKA long-term therapy
DVT and cancer	LMWH 3–6 mo
	Then VKA or LMWH indefinitely until cancer resolves

LMWH = low molecular weight heparin; VKA = vitamin K antagonist.

Source: Adapted with permission from Kearon C, Kahn SR, Agnelli G, et al:

Antithrombotic therapy for venous thromboembolic disease: American College of Chest Physicians Evidence-Based Clinical Practice Guidelines (8th edition). *Chest* 133:454S, 2008.

In contrast to patients with thrombosis related to transient risk factors, patients with idiopathic VTE are much more likely to develop recurrence (rates as high as 40% at 10 years). In this latter group of patients, numerous clinical trials have compared 3 to 6 months of anticoagulation therapy with extended-duration warfarin therapy, both at low intensity (INR of 1.5 to 2.0) and at conventional intensity (INR of 2.0 to 3.0). In patients with idiopathic DVT, extended-duration antithrombotic therapy is associated with a relative reduction in the rate of recurrent VTE by 75% to >90%. In addition, conventional-intensity warfarin reduces the risk even further compared with low-intensity warfarin (0.7 events per 100 person-years vs. 1.9 events per 100 person-years), but the rate of bleeding complications is no different.

In patients with VTE in association with a hypercoagulable condition, the optimal duration of anticoagulation therapy is influenced more by the clinical circumstances at the time of the VTE (idiopathic vs. secondary) than by the actual presence or absence of the more common thrombophilic conditions. In patients with VTE related to malignancy, increasing evidence suggests that longer-term therapy with LMWH (up to 6 months) is associated with a

lower VTE recurrence rate than treatment using conventional vitamin K antagonists.

The primary complication of warfarin therapy is hemorrhage, and the risk is related to the magnitude of INR prolongation. Depending on the INR and the presence of bleeding, warfarin anticoagulation may be reversed by (a) omitting or decreasing subsequent dosages, (b) administering oral or parenteral vitamin K, or (c) administering fresh-frozen plasma, prothrombin complex concentrate, or recombinant factor VIIa. Warfarin therapy rarely may be associated with the development of skin necrosis and limb gangrene. These conditions occur more commonly in women (4:1), and the most commonly affected areas are the breast, buttocks, and thighs. This complication, which usually occurs in the first days of therapy, is occasionally, but not exclusively, associated with protein C or S deficiency and malignancy. Patients who require continued anticoagulation may restart low-dose warfarin (2 mg) while receiving concomitant therapeutic heparin. The warfarin dosage is then gradually increased over a 1- to 2-week period.

Systemic and Catheter-Directed Thrombolysis

Patients with extensive proximal DVT may benefit from systemic thrombolysis or catheter-directed thrombolysis, which can potentially reduce acute symptoms more rapidly than anticoagulation alone. These techniques also may decrease the development of postthrombotic syndrome. Several thrombolysis preparations are available, including streptokinase, urokinase, alteplase (recombinant tissue plasminogen activator), reteplase, and tenecteplase. All these agents share the ability to convert plasminogen to plasmin, which leads to the degradation of fibrin. They differ with regard to their half-lives, their potential for inducing fibrinogenolysis (generalized lytic state), their potential for antigenicity, and their FDA-approved indications for use.

Streptokinase is purified from beta-hemolytic *Streptococcus* and is approved for the treatment of acute myocardial infarction, PE, DVT, arterial thromboembolism, and occluded central lines and arteriovenous shunts. It is not specific for fibrin-bound plasminogen, however, and its use is limited by its significant rates of antigenicity. Fevers and shivering occur in 1 to 4% of patients. Urokinase is derived from human neonatal kidney cells, grown in tissue culture. Currently, it is only approved for lysis of massive PE or PE associated with unstable hemodynamics. Alteplase, reteplase, and tenecteplase all are recombinant variants of tissue plasminogen activator. Alteplase is indicated for the treatment of acute myocardial infarction, acute ischemic stroke, and acute massive PE. However, it often is used for catheter-directed

thrombolysis of DVT. Reteplase and tenecteplase are indicated only for the treatment of acute myocardial infarction.

Systemic thrombolysis was evaluated in numerous older prospective and randomized clinical trials, and its efficacy was summarized in a recent Cochrane Review. In 12 studies involving over 700 patients, systemic thrombolysis was associated with significantly more clot lysis [relative risk (RR) 0.24 to 0.37] and significantly less postthrombotic syndrome (RR 0.66). However, venous function was not significantly improved. In addition, more bleeding complications did occur (RR 1.73), but the incidence appears to have decreased in later studies, probably due to improved patient selection.

In an effort to minimize bleeding complications and increase efficacy, catheter-directed thrombolytic techniques have been developed for the treatment of symptomatic DVT. With catheter-directed therapy, venous access may be achieved through percutaneous catheterization of the ipsilateral popliteal vein, retrograde catheterization through the contralateral femoral vein, or retrograde cannulation from the internal jugular vein. Multi-side-hole infusion catheters, with or without infusion wires, are used to deliver the lytic agent directly into the thrombus.

The efficacy of catheter-directed urokinase for the treatment of symptomatic lower extremity DVT has been reported in a large multicenter registry. Two hundred twenty-one patients with iliofemoral DVT and 79 patients with femoropopliteal DVT were treated with catheter-directed urokinase for a mean of 53 hours. Complete lysis was seen in 31% of the limbs, 50 to 99% lysis in 52% of the limbs, and <50% lysis in 17%. Overall, 1-year primary patency was 60%. Patency was higher in patients with iliofemoral DVT than in patients with femoropopliteal DVT (64% vs. 47%, $P < .01$). In addition, patients with acute symptoms (≤ 10 days) had a greater likelihood of complete lysis (34%) than patients with chronic symptoms (> 10 days; 19%). Major bleeding occurred in 11%, but neurologic involvement and mortality were rare (both 0.4%). Adjunctive stent placement to treat residual stenosis and/or short segment occlusion was required in 103 limbs.

One small randomized trial and numerous other retrospective studies have demonstrated similar rates of thrombolysis, with some also showing improved valve preservation and quality of life. Combining thrombolysis with percutaneous thrombus fragmentation and extraction has the added benefit of decreasing the infusion time, the hospital stay, and the overall cost of treatment. These studies, as well as the current ACCP guidelines, suggest that catheter-directed thrombolysis (with adjunctive angioplasty, venous stenting, and pharmacomechanical fragmentation and extraction) may be useful in selected patients with extensive iliofemoral

DVT. Patients should have a recent onset of symptoms (<14 days), good functional status, decent life expectancy, and low bleeding risk.

Inferior Vena Caval Filters

Since the introduction of the Kimray-Greenfield filter in the United States in 1973, numerous vena caval filters have been developed. Although the designs are variable, they all prevent pulmonary emboli, while allowing continuation of venous blood flow through the IVC. Early filters were placed surgically through the femoral vein. Currently, less invasive techniques allow percutaneous filter placement through a femoral vein, internal jugular vein, or small peripheral vein under fluoroscopic or ultrasound guidance. Complications associated with IVC filter placement include insertion site thrombosis, filter migration, erosion of the filter into the IVC wall, and IVC thrombosis. The rate of fatal complications is <0.12%.

Placement of an IVC filter is indicated for patients who develop recurrent DVT (significant propagation of the original thrombus or proximal DVT at a new site) or PE despite adequate anticoagulation therapy and for patients with pulmonary hypertension who experience recurrent PE. In patients who receive IVC filters for these indications, therapeutic anticoagulation should be continued. The duration of anticoagulation is determined by the underlying VTE and not by the presence of the IVC filter itself. Practically speaking, however, many patients who require an IVC filter for recurrent VTE are the same ones who would benefit most from indefinite anticoagulation. The other major indication for placement of an IVC filter is a contraindication to, or complication of, anticoagulation therapy in the presence of an acute proximal DVT. In patients who are not able to receive anticoagulants due to recent surgery or trauma, the clinician should continually reassess if antithrombotic agents may be started safely at a later date. Even some patients who develop anticoagulation-associated bleeding complications may be able to restart therapy at a lower intensity of anticoagulation later in the hospital course. As before, the clinical circumstances surrounding the VTE should determine the duration of anticoagulation.

Placement of permanent IVC filters has been evaluated as an adjunct to routine anticoagulation in patients with proximal DVT. In this study, routine IVC filter placement did not prolong early or late survival in patients with proximal DVT but did decrease the rate of PE (hazard ratio, 0.22; 95% confidence interval, 0.05 to 0.90). An increased rate of recurrent DVT was seen in patients with IVC filters (hazard ratio, 1.87; 95% confidence interval, 1.10 to 3.20). More controversial indications for IVC filter placement include prophylaxis against PE

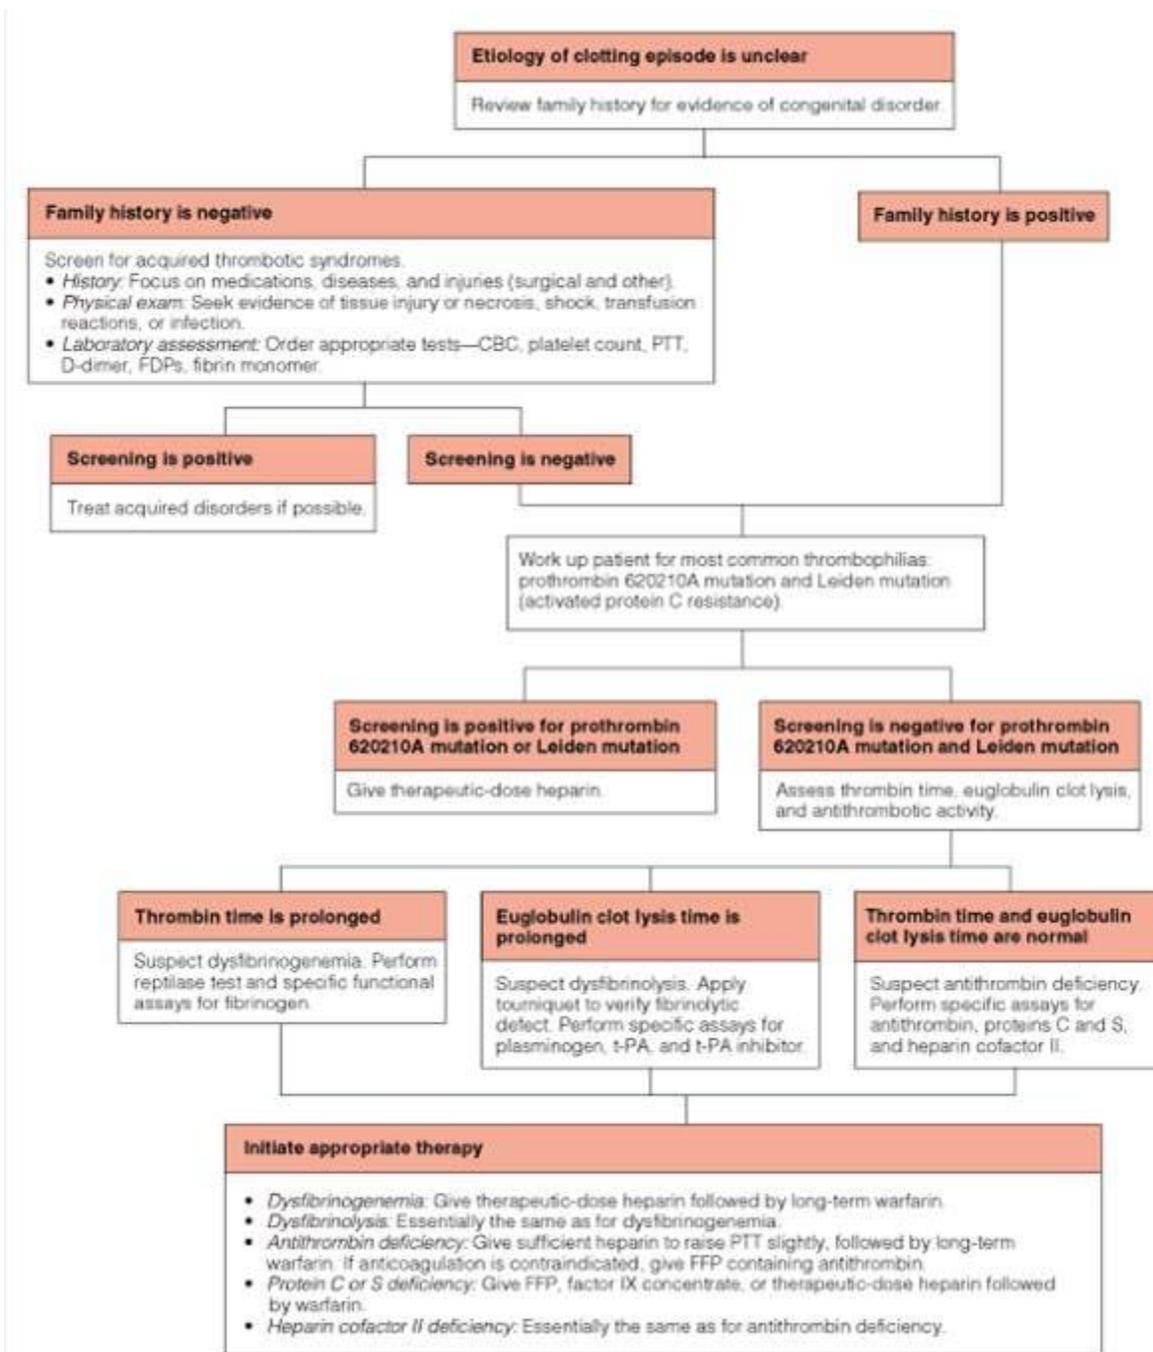

in patients receiving catheter-directed thrombolysis and in high-risk patients without established DVT or PE.

Hypercoagulability States

Certain patients seem to have a tendency to clot spontaneously. So-called hypercoagulability states were long thought to exist, but they were difficult to document except on clinical grounds. Currently, however, these clotting tendencies are better understood, thanks in large part to recognition of the role of antithrombins. If an antithrombin deficiency exists and clotting goes unchecked, activation of a clotting cascade could theoretically progress to clotting throughout the entire vasculature. Another important development was the recognition that deficiencies of certain natural clot-removing substances in the blood may lead to a clinical thrombotic tendency. Both types of deficiency can be either acquired or congenital.

Screening

When the etiology of a clotting episode is unclear, the family history should be reviewed for evidence of a congenital disorder. Even if the history is negative, the patient should be screened for both acquired and congenital disorders (table 6).

Acquired Clotting Conditions

Screening for acquired clotting conditions [see Table 7] is based on the history, physical examination, and laboratory assessment. The history should include medications, diseases, and surgical procedures or other injuries. Examination may disclose causes of hypercoagulability. Soft tissue injury, for example, is a potent activator of the coagulation system. If the injury is severe enough, it may be capable of causing a severe acquired coagulopathy. The problem is usually obvious, but on occasion, detailed study may be necessary to identify tissue damage or ischemic injury to bowel or extremities. Hypovolemia—especially hypovolemic

shock markedly reduces clotting time: blood from a patient in profound shock may clot instantaneously in the syringe as it is being drawn. The breakdown of red cells in a hemolytic transfusion reaction can cause clotting. Severe infection, especially from gram-negative organisms, is a potent activator of coagulation.

Table 7. Etiology of Acquired Hypercoagulability

Tissue and cellular damage
Shock
Trauma
Surgery
Tissue necrosis
Transfusion necrosis
Drugs
Estrogens
Drug reactions and interactions
Heparin platelet antibody
Warfarin
Disease
Blood dyscrasias
Cancer
Diabetes
Homocystinuria
Hyperlipidemia
Presence of lupuslike anticoagulant
Severe infection
Pregnancy

Of the acquired hypercoagulability syndromes, Trousseau syndrome is a particularly important condition for surgeons to recognize because it occurs in the surgical population (cancer patients) and must be treated with heparin (it is unresponsive to warfarin). It occurs when an adenocarcinoma secretes a protein recognized by the body as tissue factor, resulting in multiple episodes of venous thromboembolism over time (migratory thrombophlebitis). Simple depletion of vitamin K-dependent factors is ineffective. Patients should receive therapeutic-dose heparin indefinitely or until the cancer is brought into remission.

Laboratory screening may facilitate diagnosis. A complete blood count may document the presence of polycythemia or leukemia. Thrombocytopenia may be a manifestation of a hypercoagulable disorder, and thrombocytopenia after the administration of heparin raises the possibility of intravascular platelet aggregation. A prolonged aPTT is suggestive of lupuslike anticoagulant. Increased levels of D-dimers, fibrin degradation products (FDPs), or fibrin

monomers in the plasma may reflect low-grade intravascular coagulation.

Congenital Clotting Conditions

Congenital clotting tendencies can result from deficiencies in inhibitors of thrombosis (antithrombin, proteins C and S, and possibly heparin cofactor II), dysfibrinogenemias, or dysfibrinolysis [see Table 8]. Most congenital clotting defects are transmitted as an autosomal dominant trait. A negative family history does not preclude inherited thrombophilia, because the defects have a low penetrance, and fresh mutations may have occurred.

Table 8. Congenital Clotting Disorders

INITIAL LABORATORY ASSESSMENT

Initial evaluation of a patient with an unexplained thrombotic episode should be directed at the most common causes of hypercoagulability. Acquired causes of clotting are more commonly seen by surgeons than congenital causes and therefore must be excluded first. If a clotting disorder is determined to be congenital, a laboratory workup should be undertaken. Several of the relevant assays "specifically, the functional assays" should be performed after the acute phase of the disorder has passed. If they are performed during the acute phase, levels of several antithrombotics (e.g., antithrombin and proteins C and S) will be misleadingly low not because deficiencies of these substances caused the underlying thrombotic process but because they were consumed in that process.

Specific Causes Of Thrombotic Tendency

The most common congenital causes of accelerated clotting are mutations of prothrombin (prothrombin G20210A mutation) and factor V (Leiden mutation, or activated protein C resistance). The prevalence of each of these ranges from 1% to 5% in the general population and may be much higher in specific ethnic subpopulations.¹ Each mutation may be identified conclusively by means of polymerase chain reaction (PCR) techniques. Detection of these mutations, unlike assays for antithrombin and proteins C and S, is not dependent on the patient's current inflammatory state. It must be remembered that the presence of one of these mutations, especially in the heterozygous form, does not imply that it is the sole cause of thrombosis. In many patients, a second precipitating factor must be present for the pathologic genetic thrombotic potential to be manifested.

Prothrombin G20210A Mutation

The prothrombin G20210A mutation is known to involve a single amino acid substitution in the prothrombin gene, but precisely how this increases the risk of venous thromboembolism is unclear. The one apparent manifestation of the mutation is a 15% to 40% increase in circulating prothrombin. Regardless of the mechanism at work, patients who are at least heterozygous for the trait are at two- to sixfold greater risk for venous thromboembolism than those without the mutation.

Resistance to Activated Protein C (Factor V Leiden)

Resistance of human clotting factors to inactivation by activated protein C is believed to be the most common inherited procoagulant disorder.¹¹⁴ Normally, activated factor V is degraded by activated protein C in the presence of membrane surface as part of normal regulation of thrombosis. Activated protein C resistance is caused by a single substitution mutation in the factor V gene, which is passed in an autosomal dominant fashion. The mutant factor V that results, termed factor V Leiden, is resistant to inactivation by activated protein C and thus has a greater ability to activate thrombin and accelerate clotting.

Two techniques are commonly used to diagnose this disorder. The first is a functional assay that compares a standard aPTT to one performed in the presence of exogenous activated protein C. If the latter aPTT does not exhibit significant prolongation, the patient is probably

resistant to activated protein C. The results of this assay must be interpreted with caution if the patient is still in the acute phase of the illness. The second technique, which is more reliable, involves direct detection of the mutation via PCR analysis of DNA.

Antithrombin Deficiency

Antithrombin (once termed antithrombin III) is a 65 kd protein that decelerates the coagulation system by inactivating activated factors, primarily factor Xa and thrombin but also factors XII, XI, and IX. Antithrombin therefore acts as a scavenger of activated clotting factors. Its activity is enhanced 100-fold by the presence of heparans on the endothelial surface and 1,000-fold by administration of exogenous heparin.

Congenital antithrombin deficiency occurs in approximately 0.01% to 0.05% of the general population and 2% to 4% of patients with venous thrombosis. The trait is passed on as an autosomal dominant trait, with the heterozygous genotype being incompatible with life. Antithrombin-deficient patients are at increased risk for thromboembolism when their antithrombin activity falls below 70% of normal.

Patients with congenital antithrombin deficiency frequently present after a stressful event. They usually have DVT but sometimes have PE. If anticoagulation is not contraindicated, the treatment of choice is heparin at a dosage sufficient to raise the aPTT to the desired level, followed by warfarin. If anticoagulation is contraindicated (as it is during the peripartum period), antithrombin concentrate should be given to raise the antithrombin activity to 80% to 120% of normal during the period when anticoagulants cannot be given.

Acquired antithrombin deficiency is a well-recognized entity. In most patients undergoing severe systemic stress, antithrombin levels fall below normal. Patients with classic risk factors for venous thromboembolism tend to have the lowest levels.

Protein C and Protein S Deficiency

Protein C is a 62 kd glycoprotein with a half-life of 6 hours. Because it is vitamin K dependent, a deficiency will develop in the absence of vitamin K. Acquired protein C deficiency is seen in liver disease, malignancy, infection, the postoperative state, and disseminated intravascular coagulation. Protein C deficiency occurs in approximately 4% to 5% of patients younger than 40 to 45 years who present with unexplained venous thrombosis. It is transmitted as an autosomal dominant trait, and the family history is usually positive for a

clotting tendency. Protein C levels range from 70% to 164% of normal in patients without a clotting tendency; levels below 70% of normal are associated with a thrombotic tendency. The most appropriate tests for screening are functional assays; there are cases of dysfunctional protein C deficiency in which protein C antigen levels are normal but protein C activity is low, and these would not be detected by the usual immunoassays.

Protein S is a vitamin K-dependent protein that acts as a cofactor for activated protein C by enhancing protein C-induced inactivation of activated factor V. The incidence of protein S deficiency is similar to that of protein C deficiency. It is transmitted as a dominant trait, and the family history is often positive for a thrombotic tendency.

Hyperhomocysteinemia

Although hyperhomocysteinemia is more commonly associated with cardiac disease and arterial thrombosis, it may also be associated with an increased incidence of venous thromboembolism. This association is not as strong as those already discussed. Accordingly, anticoagulation of asymptomatic patients with elevated homocysteine levels is not currently recommended.

Dysfibrinogenemia

More than 100 qualitative abnormalities of fibrinogen (dysfibrinogenemias) have been reported. Dysfibrinogenemias are inherited in an autosomal dominant manner, with most patients being heterozygous. Most patients with dysfibrinogenemia have either no clinical symptoms or symptoms of a bleeding disorder; a minority (about 11%) have clinical features of a recurrent thromboembolic disorder. Congenital dysfibrinogenemias associated with thrombosis account for about 1% of cases of unexplained venous thrombosis occurring in young people. The most commonly observed functional defect in such dysfibrinogenemias is abnormal fibrin monomer polymerization combined with resistance to fibrinolysis. Decreased binding of plasminogen and increased resistance to lysis by plasmin have been noted.

In addition to a prolonged TT, patients who have dysfibrinogenemia associated with thromboembolism may have a prolonged INR. The diagnosis is confirmed if the reptilase time is also prolonged. Measured with clotting techniques, fibrinogen levels may be slightly or moderately low; measured immunologically, levels may be normal or even increased.

Dysfibrinolysis

Fibrinolysis can be impaired by inherited deficiencies of plasminogen, defective release of t-PA from the vascular endothelium, and high plasma levels of regulatory proteins (e.g., t-PA inhibitors). In addition, factor XII (contact factor) deficiency may induce failure of fibrinolysis activation.

Inherited plasminogen deficiency is probably only rarely responsible for unexplained DVT in young patients. It is transmitted as an autosomal dominant trait. In heterozygous persons with a thrombotic tendency, plasminogen activity is about one half normal (3.9 to 8.4 $\mu\text{mol/ml}$). The euglobulin clot lysis time is prolonged. Functional assays should be carried out, and there should be full transformation of plasminogen into plasmin activators.

The important role of t-PA inhibitors I and II in the regulation of fibrinolysis is well defined. In normal plasma, t-PA inhibitor I is the primary inhibitor for both t-PA and urokinase. Release of t-PA inhibitor I by platelets results in locally increased concentrations where platelets accumulate. The ensuing local inhibition of fibrinolysis may help stabilize the hemostatic plug. t-PA inhibitor II is present in and secreted by monocytes and macrophages.

Factor XII deficiency is a rare cause of impaired fibrinolysis. Initial contact activation of factor XII not only results in activation of the clotting cascade and of the inflammatory response but also leads to plasmin generation. This intrinsic activation of fibrinolysis requires factor XII, prekallikrein, and high-molecular-weight kininogen. Patients with factor XII deficiencies can be identified by a prolonged aPTT in the absence of clinical bleeding.

Operative Venous Thrombectomy

In patients with acute iliofemoral DVT, surgical therapy is generally reserved for patients who worsen with anticoagulation therapy and those with phlegmasia cerulea dolens and impending venous gangrene. If the patient has phlegmasia cerulea dolens, a fasciotomy of the calf compartments is first performed. In iliofemoral DVT, a longitudinal venotomy is made in the common femoral vein and a venous balloon embolectomy catheter is passed through the thrombus into the IVC and pulled back several times until no further thrombus can be extracted. The distal thrombus in the leg is removed by manual pressure beginning in the foot. This is accomplished by application of a tight rubber elastic wrap beginning at the foot and extending to the thigh. If the thrombus in the femoral vein is old and cannot be extracted, the vein is ligated. For a thrombus that extends into the IVC, the IVC is exposed transperitoneally

and the IVC is controlled below the renal veins. The IVC is opened and the thrombus is removed by gentle massage. An intraoperative completion venogram is obtained to determine if any residual thrombus or stenosis is present. If a residual iliac vein stenosis is present, intraoperative angioplasty and stenting can be performed. In most cases, an arteriovenous fistula is then created by anastomosing the great saphenous vein (GSV) end to side with the superficial femoral artery in an effort to maintain patency of the thrombectomized iliofemoral venous segment. Heparin is administered postoperatively for several days. Warfarin anticoagulation is maintained for at least 6 months after thrombectomy. Complications of iliofemoral thrombectomy include PE in up to 20% of patients and death in <1% of patients.

One study followed 77 limbs for a mean of 8.5 years after thrombectomy for acute iliofemoral DVT. In limbs with successful thrombectomies, valvular competence in the thrombectomized venous segment was 80% at 5 years and 56% at 10 years. More than 90% of patients had minimal or no symptoms of postthrombotic syndrome. There were 12 (16%) early thrombectomy failures. Patients were required to wear compression stockings for at least 1 year after thrombectomy.

Survival rates for surgical pulmonary embolectomy have improved over the past 20 years with the addition of cardiopulmonary bypass. Emergency pulmonary embolectomy for acute PE is rarely indicated. Patients with preterminal massive PE (Fig. 5) for whom thrombolysis has failed or who have contraindications to thrombolytics may be candidates for this procedure. Open pulmonary artery embolectomy is performed through a posterolateral thoracotomy with direct visualization of the pulmonary arteries. Mortality rates range between 20 and 40%.

Fig. 5. Autopsy specimen showing a massive pulmonary embolism.

Percutaneous catheter-based techniques for removal of a PE involve mechanical thrombus fragmentation or embolectomy using suction devices. Mechanical clot fragmentation is followed by catheter-directed thrombolysis. Results of catheter-based fragmentation are based on small case series. In a study in which a fragmentation device was used in 10 patients with acute massive PE, fragmentation was successful in 7 patients with a mortality rate of 20%.⁶⁵ Transvenous catheter pulmonary suction embolectomy has also been performed for acute massive PE with a reported 76% successful extraction rate and a 30-day survival of 70%.⁶⁶

Prophylaxis

Patients who undergo major general surgical, gynecologic, urologic, and neurosurgical procedures without thromboprophylaxis have a significant incidence of perioperative DVT (15 to 40%). The incidence is even higher with major trauma (40 to 80%), hip and knee replacement surgery (40 to 60%), and spinal cord injury (60 to 80%). The goal of prophylaxis is to reduce the mortality and morbidity associated with VTE. The first manifestation of VTE may be a life-threatening PE (Fig. 6), and as indicated earlier, clinical evaluation to detect DVT before PE is unreliable.

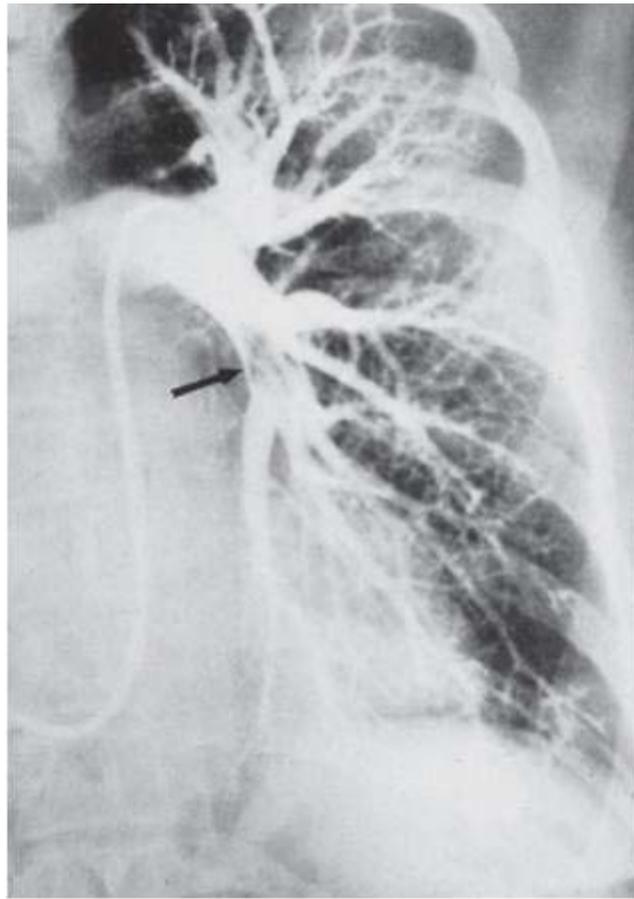

Fig. 6. Pulmonary angiogram showing a pulmonary embolism (*arrow*).

Effective methods of VTE prophylaxis involve the use of one or more pharmacologic or mechanical modalities. Currently available pharmacologic agents include low-dose UFH, LMWH, synthetic pentasaccharides, and vitamin K antagonists. Mechanical methods include intermittent pneumatic compression (IPC) and graduated compression stockings. Aspirin therapy alone is not adequate for DVT prophylaxis. These prophylaxis methods vary with regard to their efficacy, and the 2008 ACCP Clinical Practice Guidelines stratify their uses according to the patient's level of risk (Table 6).

Table 6. Thromboembolism Risk and Recommended Thromboprophylaxis in Surgical Patients

Level of Risk	Approximate DVT Risk without Thromboprophylaxis (%)	Suggested Thromboprophylaxis Options
Low risk	<10	No specific thromboprophylaxis
Minor surgery in mobile patients		Early and "aggressive" ambulation
Moderate risk	10-40	LMWH (at recommended doses), LDUH bid or tid, fondaparinux
Most general, open gynecologic, or urologic surgery		Mechanical thromboprophylaxis
Moderate VTE risk plus high bleeding risk		
High risk	40-80	LMWH (at recommended doses), fondaparinux, oral vitamin K antagonist (INR 2-3)
Hip or knee arthroplasty, hip fracture surgery		
Major trauma, spinal cord injury		Mechanical thromboprophylaxis
High VTE risk plus high bleeding risk		

Complications

Complications after venous thrombosis can vary from life threatening to chronically debilitating. Pulmonary embolism develops as venous thrombi break off from their location of origin and travel through the right heart and into the pulmonary artery, causing a ventilation perfusion defect and cardiac strain. PE occurs in approximately 10% of patients with acute deep venous thrombosis and can cause up to 10% of in hospital deaths.^{60,61} However, most patients (up to 75%) are asymptomatic. Traditionally, proximal venous thrombosis are thought to be at highest risk for causing pulmonary emboli; however, the single largest autopsy series ever performed to specifically to look for the source of fatal PE was performed by Havig in 1977, who found that one third of the fatal emboli arose directly from the calf veins.⁶

PHLEGMASIA ALBA AND CERULEA DOLENS

More than 600,000 cases of venous thromboembolism are estimated to occur each year in the United States. Pulmonary embolism (PE) complicates approximately 50% of cases of untreated proximal deep venous thrombosis (DVT) and contributes to 10-15% of all hospital deaths. Less frequent manifestations of venous thrombosis include phlegmasia alba dolens, phlegmasia cerulea dolens (PCD), and venous gangrene. These form a clinical spectrum of the same disorder. All 3 manifestations result from acute massive venous thrombosis and obstruction of the venous drainage of an extremity

History of the Procedure

In the 16th century, Fabricius Hildanus first described the clinical syndrome of what is currently called PCD. In 1938, Gregoire made an outstanding description of the condition and used the term PCD to differentiate ischemia-associated massive venous thrombosis from phlegmasia alba dolens, which describes fulminant venous thrombosis without ischemia.¹ The exact incidence of these disorders is not well reported.

In 1939, Leriche and Geissendorfer performed the first thrombectomy for cases of PCD.² Historically, surgical thrombectomy has been the procedure of choice for PCD refractory to medical therapy and in patients with established or impending gangrene.

Frequency

More than 600,000 cases of venous thromboembolism are estimated to occur annually in the United States. Phlegmasia alba dolens, PCD, and venous gangrene occur at any age but are more common during the fifth and sixth decades of life. Incidence is higher in females than in males.

Etiology

The main causative factor in phlegmasia is massive thrombosis and occlusion of major venous channels with significantly compromised venous outflow. Multiple triggering factors exist. Malignancy is the most common triggering factor and is present in approximately 20-40% of patients with PCD. Other associated risk factors include hypercoagulable syndrome, surgery, trauma, ulcerative colitis, gastroenteritis, heart failure, mitral valve stenosis, vena caval filter insertion, and May-Thurner syndrome (compression of the left iliac vein by the right iliac artery). Pregnancy has often been associated with phlegmasia alba dolens, especially during the third trimester when the uterus is large enough to compress the left common iliac vein against the pelvic rim (ie, milk leg syndrome). Finally, 10% of patients with phlegmasia have no apparent risk factors.

Pathophysiology

In phlegmasia alba dolens, the thrombosis involves only major deep venous channels of the extremity, therefore sparing collateral veins. The venous drainage is decreased but still

present; the lack of venous congestion differentiates this entity from PCD.

In PCD, the thrombosis extends to collateral veins, resulting in venous congestions with massive fluid sequestration and more significant edema. Without established gangrene, these phases are reversible if proper measures are taken.

Of PCD cases, 40-60% also have capillary involvement, which results in irreversible venous gangrene that involves the skin, subcutaneous tissue, or muscle. Under these conditions, the hydrostatic pressure in arterial and venous capillaries exceeds the oncotic pressure, causing fluid sequestration in the interstitium. Venous pressure may increase rapidly, as much as 16- to 17-fold within 6 hours. Fluid sequestration may reach 6-10 L in the affected extremity within days. Circulatory shock, which is present in about one third of patients, and arterial insufficiency may ensue.

The exact mechanism for the compromised arterial circulation is debatable but may involve shock, increased venous outflow resistance, and collapse of arterioles due to increased interstitial pressure. Vasospasm of the resistance vessels has also been hypothesized but has never been observed experimentally or radiographically.

Presentation

In the lower extremities, left-sided involvement is more common by a 3:1 or 4:1 ratio. Involvement of upper extremities occurs in less than 5% of patients with PCD. Manifestations may be gradual or fulminant. Of PCD cases, 50-60% are preceded by phlegmasia alba dolens, with symptoms of edema, pain, and blanching (alba) without cyanosis. The blanching, which previously was thought to be caused by arterial vasospasm, is caused by subcutaneous edema, without venous congestion.

Patients with PCD present with the clinical triad of edema, agonizing pain, and cyanosis. Massive fluid sequestration may lead to bleb and bullae formation. The pain is constant, usually starting at the femoral triangle and then progressing to the entire extremity. Cyanosis is the pathognomonic finding of PCD, progressing from distal to proximal areas.

When venous gangrene occurs, it has a similar distribution with the cyanosis. Arterial pulses may be present when the venous gangrene is superficial; however, gangrene that involves

the muscular compartment may result in increased compartment pressures and a pulse deficit. In addition, the pulses may be difficult to appreciate because of the significant edema. Various degrees of shock may be present because of significant fluid loss.

Indications

Historically, surgical thrombectomy has been the procedure of choice for phlegmasia cerulea dolens (PCD) refractory to medical therapy and for patients with established or impending gangrene. The standard treatment of phlegmasia and venous gangrene is evolving, but most clinicians attempt endovascular approaches to thrombolysis, if possible.

Relevant Anatomy

The main causative factor in phlegmasia is massive deep venous thrombosis (DVT) and occlusion of major venous channels with significantly compromised venous outflow. In phlegmasia alba dolens, the thrombosis involves only major deep venous channels of the extremity, therefore sparing collateral veins and preserving some venous outflow from the limb. In phlegmasia cerulea dolens (PCD), the thrombosis extends to collateral veins, with complete obstruction of venous outflow, resulting in massive venous congestion and fluid sequestration and more significant edema.

Contraindications

For phlegmasia alba dolens and mild nongangrenous forms of phlegmasia cerulea dolens (PCD), conservative medical treatment, rather than surgical thrombectomy, should be the initial course of therapy. Thrombolysis may be initiated if conservative management does not elicit a response and if the patient has no contraindication to lytic therapy.

Surgical thrombectomy cannot open the small venules that are affected in venous gangrene, and it does not prevent valvular incompetence or postphlebotic syndrome. For these reasons, thrombolysis seems to be an attractive alternative in the management of PCD and venous gangrene.

Imaging Studies

The diagnoses of phlegmasia alba dolens, phlegmasia cerulea dolens (PCD), and venous gangrene are established mainly via clinical criteria with the assistance of contrast venography and duplex ultrasonography.

Although venography is considered the criterion standard for diagnosis, technical difficulties may be encountered in as many as 20-25% of patients. Attempts to perform ascending venography when extensive deep system thrombosis is present may result in nonvisualization of the deep system and a nondiagnostic study result. In these cases, descending venography via the contralateral femoral vein or via the upper extremity veins may provide more information about the ilio caval system and proximal extent of the thrombus.

Recent improvements in ultrasonography have made this modality a more reliable and accurate way to assess for proximal deep venous thrombosis (DVT) with less morbidity. In addition, duplex imaging may be repeated as needed to monitor for thrombus propagation. Ultrasonography can also be performed at the bedside in patients who are critically ill or unstable. Ultrasonography is often used to guide the initial venipuncture for diagnostic venography and initiation of thrombolytic therapy.

Magnetic resonance venography (MRV) is an evolving modality of diagnostic imaging. Its principal advantage is its ability to easily reveal the proximal and distal extent of thrombus with a single study. Its principal disadvantage is the inability to image acutely ill patients with hemodynamic instability or motion artifacts due to pain.

Medical Therapy

The standard treatment of phlegmasia and venous gangrene is still evolving. The optimal therapeutic modality remains under debate. So far, the results of treatment have been moderately successful. For phlegmasia alba dolens and mild nongangrenous forms of phlegmasia cerulea dolens (PCD), conservative medical treatment, such as steep limb elevation, anticoagulation with intravenous administration of heparin, and fluid resuscitation, should be the initial course of therapy.

Initiate heparin administration with an intravenous bolus of 80-100 U/kg, followed by a continuous infusion of 15-18 U/kg/h. Frequently monitor the activated partial thromboplastin time (aPTT), with a goal range of 2-2.5 times the laboratory reference range. Frequently monitor platelet counts to allow the early detection of heparin-induced thrombocytopenia.

The purpose of rapid heparin anticoagulation is to decrease the risk of proximal clot propagation or thromboembolism. Heparin does not directly affect limb swelling. The best nonsurgical method to decrease edema is steep leg elevation.

Recent studies have demonstrated that low molecular weight heparins are safe and effective in the treatment of proximal deep venous thrombosis (DVT) and pulmonary embolism (PE); however, no good evidence supports the use of these newer agents in phlegmasia and venous gangrene.

If heparin-induced thrombocytopenia occurs, immediately discontinue the use of heparin and replace it with an alternative anticoagulant. Danaparoid and lepirudin are effective alternative agents; however, heparin-associated antibodies exhibit a 10-19% cross-reactivity with danaparoid. Thus, perform cross-reactivity testing before the initiation of danaparoid in patients with these antibodies. Lepirudin is a direct thrombin inhibitor that does not demonstrate any cross-reactivity. The recommended dosage of lepirudin in patients without renal failure is 0.4 mg/kg as an intravenous bolus followed by a continuous infusion of 0.15 mg/kg/h. Use aPTT to monitor therapy, with a goal range of 2-2.5 times the laboratory reference range.

Continue long-term anticoagulation with warfarin (or other coumarin derivatives) for at least 6 months. Life-long anticoagulation is recommended in patients with hypercoagulable states.

Patients should wear long-term prescription compression stockings with at least 30-40 mm Hg of graded pressure. Many physicians erroneously have the patient fitted for a prescription stocking while the limb is still severely edematous. Instead, the patient may use nonprescription stockings or an elastic bandage, in combination with elevation, to minimize edema prior to being fit for a prescription stocking.

Surgical Therapy

Surgical thrombectomy performed through a femoral venotomy allows instant decompression of the venous hypertension. An intraoperative Trendelenburg position may be

used to decrease the risk of PE. Transabdominal cavotomy and thrombectomy is an alternative approach that permits better control of the cava above the thrombus and, thus, provides protection against PE. Procedures that have been performed in an effort to decrease the rethrombosis rate include cross-pubic vein-to-vein reconstruction with polytetrafluoroethylene (PTFE) or the greater saphenous vein (GSV) or the creation of an arteriovenous fistula between the femoral artery and the GSV. These adjuvant procedures may be especially beneficial in cases that involve proximal iliofemoral vein constriction, damage, or external compression.

Concomitant administration of heparin and long-term anticoagulation are mandatory. Regardless, thrombectomy in patients with PCD is associated with a high rate of rethrombosis. Surgical thrombectomy cannot open the small venules that are affected in venous gangrene, and it does not prevent valvular incompetence or postphlebotic syndrome. The incidence of postphlebotic syndrome may be as high as 94% among survivors.

For the above reasons, thrombolysis seems to be an attractive alternative in the management of PCD and venous gangrene. In 1970, Paquet was the first to use thrombolysis for the treatment of PCD.⁴ Some authors propose catheter-directed thrombolysis directly into the vein with high doses of urokinase or tissue plasminogen activator (t-PA). Other authors support the method of intra-arterial low-dose thrombolysis via the common femoral artery, reasoning that the arterial route delivers the thrombolytic agent to the arterial capillaries and, subsequently, to the venules. The intra-arterial approach seems to be more effective in cases with venous gangrene. Systemic thrombolysis has also been used. Many authors have strongly recommended the insertion of a vena caval filter prior to initiation of thrombolytic therapy. Combine thrombolysis with heparin administration and long-term oral anticoagulation.

Fasciotomy alone or in conjunction with thrombectomy or thrombolysis reduces compartmental pressures; however, it significantly increases morbidity because of the prolonged wound healing and the risk of infection.

Finally, if all efforts fail and amputation is required, delay the procedure as long as possible. Take all precautions to reduce edema, allow venous channels to recanalize, and allow necrotic tissue to demarcate.

Preoperative Details

Patients who require emergent venous thrombectomy should have heparin continued throughout the perioperative period. Banked red blood cells should be available. The proximal extent of the thrombosis must be defined using a combination of venous ultrasonography for infrainguinal veins and retrograde venography of the iliac veins and inferior vena cava using a jugular or contralateral femoral approach. If the thrombosis extends into the iliac veins and vena cava, preparations should be made to control the cava via a right retroperitoneal incision. A high-quality fluoroscopy unit should be available to aid in catheter manipulation and completion venography.

Intraoperative Details

Operative exposure depends on the proximal and distal extent of the thrombus. The involved veins should be controlled proximally and distally prior to venotomy.

Iliac venous thrombectomy should be performed with large-bore thrombectomy balloon catheters (as large as 10F). Extension of the thrombus into the inferior vena cava may require proximal control of the cava. The anesthesiologist should apply positive airway pressure while the thrombus is being extracted from the ilio caval system. Digital subtraction venography should be performed to ascertain completeness of the thrombectomy.

Infrainguinal extraction of the thrombus is aided by the intraoperative placement of an Esmarch bandage from foot to thigh. Thrombectomy balloon catheters (3F and 4F) are passed through the femoral veins and, possibly, the posterior tibial veins as well.

Thrombolytic agents may be administered intraoperatively through the posterior tibial veins. t-PA is the most commonly used agent and may be administered intraoperatively.

After the thrombectomy is performed, an arteriovenous fistula should be constructed, connecting the proximal greater saphenous vein or one of its larger tributaries to the superficial femoral artery in an end-to-side fashion.

Completion venography should be performed to exclude the presence of residual thrombus or proximal venous stenosis. If one is present, balloon angioplasty with or without stent placement may be necessary.

When percutaneous endovascular therapy is performed as a single treatment modality, and many centers are now reporting this as a first-line therapy, the popliteal veins are usually

accessed with duplex ultrasonography as an aid. Prone positioning is rarely necessary. If extensive thrombus is present, access via the posterior tibial vein is usually successful. A 6-F sheath is usually adequate. An infusion wire is passed through the thrombus just to its proximal extent, often into the vena cava. Infusion is usually performed in the most proximal segment first, usually in the iliac veins.

A common protocol is to infuse tPA (1 mg/hr) through the infusion wire as well as through the sheath for 24 hours, then to change the sheath perfusion to lower dose heparin after 24 hours. The infusion is then performed in the superficial femoral and popliteal vein segments. Clinical improvement is often noted with clearing of the profunda venous segment. Performance of simultaneous percutaneous mechanical thrombectomy is controversial and may not give better results than postprocedure balloon dilation.

Postoperative Details

Intravenous heparin is administered throughout the postoperative period to prolong the aPTT (2-2.5 times the reference range for aPTT). This is continued until the patient is adequately anticoagulated with warfarin or one of the coumarin derivatives (international normalized ratio [INR] range of 2.0-3.0). The optimal duration of oral anticoagulation is not established.

A sequential compression device is also placed, or, at a minimum, an ace bandage is placed for control of edema. Once the edema is at its minimum, the patient may be fitted for a thigh-length compression stocking. Ambulation is encouraged, if the patient is able.

Complications

The incidence of postphlebotic syndrome may be as high as 94% among survivors. Pulmonary embolism is common, and prophylactic placement of an inferior vena cava filter is recommended in most cases. Thrombectomy in patients with phlegmasia cerulea dolens (PCD) is associated with a high rate of rethrombosis. Amputation and death are common.

Outcome and Prognosis

Despite all of the therapeutic modalities described above, phlegmasia cerulea dolens (PCD) and venous gangrene still remain life-threatening and limb-threatening conditions with

overall mortality rates of 20-40%. Pulmonary embolism (PE) is responsible for 30% of the deaths reported from PCD. Overall, amputation rates of 12-50% have been reported among survivors. The postphlebitic sequelae are apparent in 60-94% of survivors. Strict adherence to the use of long-term compression stockings helps to control chronic edema.

Future and Controversies

Phlegmasia alba dolens, phlegmasia cerulea dolens (PCD), and venous gangrene still remain a challenge to the vascular surgeon. Treatment modalities continue to evolve. Endovascular management may offer hope of successful and more effective management, with less morbidity, than traditional surgery. The role of mechanical thrombectomy, compared with thrombolysis, is unclear. Small numbers of patients and lack of randomized trials preclude clear recommendations.

SUPERIOR VENA CAVA SYNDROME

Introduction

Background

Superior vena cava syndrome (SVCS) is obstruction of blood flow through the superior vena cava (SVC). It is a medical emergency and most often manifests in patients with a malignant disease process within the thorax. A patient with superior vena cava syndrome (SVCS) requires immediate diagnostic evaluation and therapy.

William Hunter first described the syndrome in 1757 in a patient with syphilitic aortic aneurysm.¹ In 1954, Schechter reviewed 274 well-documented cases of superior vena cava syndrome (SVCS) reported in the literature; 40% of them were due to syphilitic aneurysms or tuberculous mediastinitis. In more recent times, these infections have gradually decreased as the primary cause of superior vena cava (SVC) obstruction. Lung cancer, particularly adenocarcinoma, is now the underlying process in approximately 70% of the patients with superior vena cava syndrome (SVCS). However, up to 40% of the causes are due to nonmalignant causes.

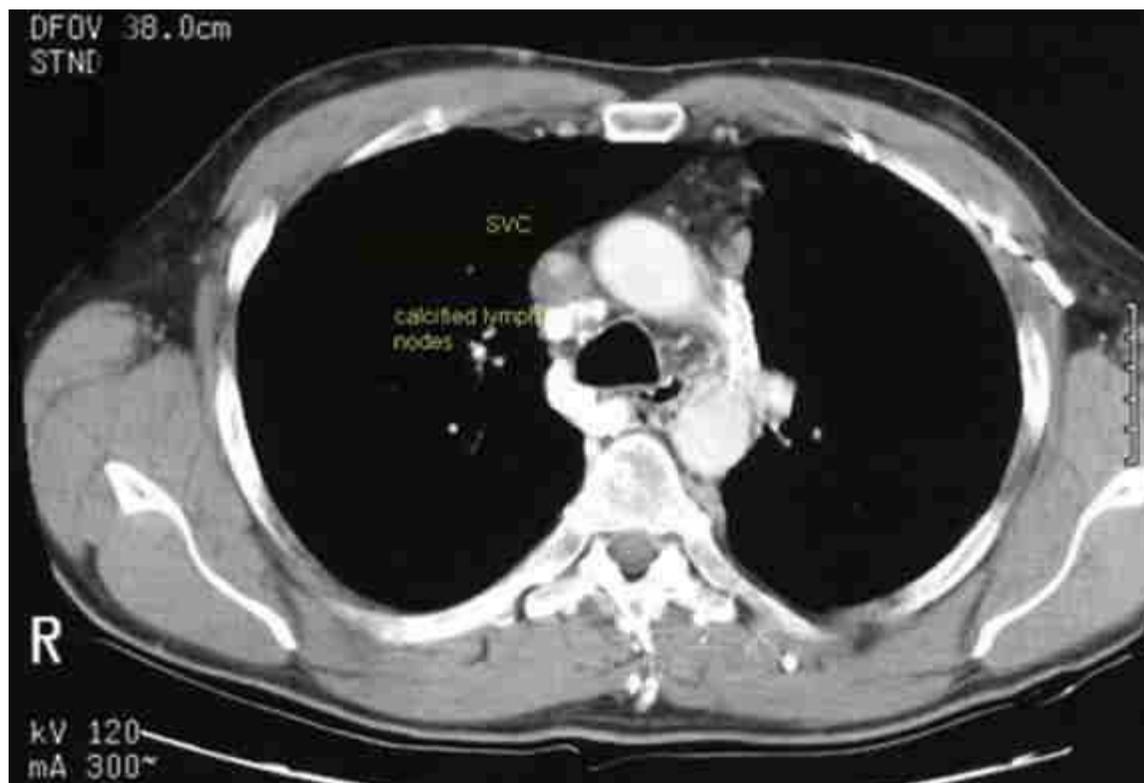

Fig. 1. Superior vena cava syndrome (case 1). The patient was a 35-year-old man with a 3-year history of progressive upper-extremity and fascial swelling. The patient had undergone treatment for histoplasmosis in the past. CT scan shows a narrowed superior vena cava with adjacent calcified lymph nodes and posterior soft tissue thickening

Pathophysiology

The superior vena cava (SVC) is the major drainage vessel for venous blood from the head, neck, upper extremities, and upper thorax. It is located in the middle mediastinum and is surrounded by relatively rigid structures such as the sternum, trachea, right bronchus, aorta, pulmonary artery, and the perihilar and paratracheal lymph nodes. It extends from the junction of the right and left innominate veins to the right atrium, a distance of 6-8 cm. It is a thin-walled, low-pressure, vascular structure. This wall is easily compressed as it traverses the right side of the mediastinum.⁷

Obstruction of the superior vena cava (SVC) may be caused by neoplastic invasion of the venous wall associated with intravascular thrombosis or, more simply, by extrinsic pressure of a tumor mass against the relatively fixed thin-walled superior vena cava (SVC). Postmortem examinations reveal that complete superior vena cava (SVC) obstruction is the result of

intravascular thrombosis in combination with extrinsic pressure. Incomplete superior vena cava (SVC) obstruction is more often secondary to extrinsic compression without thrombosis. Other causes include compression by intravascular arterial devices. The incidence is on the rise in line with the increased usage of endovascular devices.⁴

An obstructed superior vena cava (SVC) initiates collateral venous return to the heart from the upper half of the body through 4 principal pathways. The first and most important pathway is the azygous venous system, which includes the azygous vein, the hemiazygous vein, and the connecting intercostal veins. The second pathway is the internal mammary venous system plus tributaries and secondary communications to the superior and inferior epigastric veins. The long thoracic venous system, with its connections to the femoral veins and vertebral veins, provides the third and fourth collateral routes, respectively.

Despite these collateral pathways, venous pressure is almost always elevated in the upper compartment if obstruction of the superior vena cava (SVC) is present. Venous pressure as high as 200-500 cm H₂O has been recorded in patients with severe superior vena cava syndrome (SVCS).

Frequency

United States

Superior vena cava syndrome (SVCS) develops in 5-10% of patients with a right-sided malignant intrathoracic mass lesion. In 1969, Salsali and Clifton observed superior vena cava syndrome (SVCS) in 4.2% of 4960 patients with lung cancer; 80% of the tumors inducing superior vena cava syndrome (SVCS) were of the right lung. In 5 large series of small cell lung cancer, 9-19% of patients demonstrated superior vena cava syndrome (SVCS). In 1987, Armstrong and Perez found superior vena cava syndrome (SVCS) in 1.9% of 952 patients with lymphoma.

Mortality/Morbidity

Survival in patients with superior vena cava syndrome (SVCS) depends mainly on the course of the underlying disease. No mortality, per se, results directly from mild venous congestion.

In patients with benign superior vena cava syndrome (SVCS), life expectancy is unchanged.

If superior vena cava syndrome (SVCS) is secondary to a malignant process, patient survival correlates with the histology of the tumor. Patients with signs and symptoms of laryngeal and cerebral edema have the most life-threatening manifestations of this syndrome and are in danger of sudden death. Clinical observations show that approximately 10% of patients with a bronchogenic carcinoma and 45% of patients with lymphoma treated with irradiation live at least 30 months. In contrast, patients with untreated malignant superior vena cava syndrome (SVCS) survive only approximately 30 days.⁵

Race

The frequency of superior vena cava syndrome (SVCS) in different races depends largely on the frequency of lung cancer and lymphomas in these populations.

Sex

Malignant causes of superior vena cava syndrome (SVCS) are most commonly observed in males because of the high incidence of lung cancer in this population.

In contrast, no sex difference is observed in cases related to benign causes.

Age

Malignant causes of superior vena cava syndrome (SVCS) are predominantly observed in individuals aged 40-60 years.

Benign causes account for most of the cases diagnosed in individuals aged 30-40 years.

Obstruction of the superior vena cava (SVC) in the pediatric age group is rare and has a different etiologic spectrum.

Clinical

History

Early in the clinical course, partial superior vena cava (SVC) obstruction may be

asymptomatic, but more often, minor symptoms and signs are overlooked.

As the syndrome advances toward total superior vena cava (SVC) obstruction, the classic symptoms and signs become more obvious.

Dyspnea is the most common symptom and is observed in 63% of patients with superior vena cava syndrome (SVCS).^{7,10}

Other symptoms include facial swelling, head fullness, cough, arm swelling, chest pain, dysphagia, orthopnea, distorted vision, hoarseness, stridor, headache, nasal stuffiness, nausea, pleural effusions, and light-headedness.^{7,10,11}

Physical

The characteristic physical findings of superior vena cava syndrome (SVCS) include venous distension of the neck and chest wall, facial edema, upper extremity edema, mental changes, plethora, cyanosis, papilledema, stupor, and even coma.

Bending forward or lying down may aggravate the symptoms and signs.

Causes

More than 80% of cases of superior vena cava syndrome (SVCS) are caused by malignant mediastinal tumors.^{12,13,14}

Bronchogenic carcinomas account for 75-80% of all these cases, with most of these being small-cell carcinomas.³

Non-Hodgkin lymphoma (especially the large cell type) represents 10-15% of cases.

Causes of superior vena cava syndrome (SVCS) appear similar to the relative incidence of primary lung and mediastinal tumors.

Rare malignant diagnoses include Hodgkin disease, metastatic cancers,¹⁵ primary leiomyosarcomas of the mediastinal vessels, and plasmocytomas.^{16,17,18}

Nonmalignant conditions causing superior vena cava syndrome (SVCS) include mediastinal fibrosis; vascular diseases such as aortic aneurysm, vasculitis, and arteriovenous fistulas; infections such as histoplasmosis, tuberculosis, syphilis, and actinomycosis; benign mediastinal tumors such as teratoma, cystic hygroma, thymoma, and dermoid cyst; cardiac causes, such as pericarditis and atrial myxoma; and thrombosis related to the presence of central vein catheters. These account for approximately 22% of the causes of superior vena cava syndrome (SVCS).

Imaging Studies

Patients presenting with overt superior vena cava syndrome (SVCS) may be diagnosed by means of physical examination alone. However, subtle presentations require diagnostic imaging. Chest radiography may reveal a widened mediastinum or a mass in the right side of the chest. Only 16% of the patients studied by Parish and colleagues in 1981 had normal findings on chest radiography.

CT has the advantage of providing more accurate information on the location of the obstruction and may guide attempts at biopsy by mediastinoscopy, bronchoscopy, or percutaneous fine-needle aspiration.

It also provides information on other critical structures such as the bronchi and the vocal cords.

The additional information is necessary because the involvement of these structures requires prompt action for relief of pressure.

MRI has not been sufficiently investigated, but it appears promising.

It has several potential advantages over CT scanning, including the fact that it provides images in several planes of view and allows direct visualization of blood flow. Furthermore, MRI does not require iodinated contrast material. This is especially important when stenting is anticipated.

Disadvantages may include increased scanning time with attendant problems in patient compliance and increased cost.

Invasive contrast venography is the most conclusive diagnostic tool.

It precisely defines the etiology of obstruction.

It is especially important if surgical management is being considered for the obstructed vena cava.

Radionuclide technetium-99m venography is an alternative minimally invasive method of imaging the venous system. Although images obtained by this method are not as well defined as those achieved with contrast venography, they demonstrate potency and flow patterns.

Gallium single-proton emission CT scanning may be of value in select cases.

Procedures

Most patients with superior vena cava syndrome (SVCS) present before the primary diagnosis is established.

Controversy often arises in the treatment of a patient with superior vena cava syndrome (SVCS) in regard to the need for pathologic confirmation of malignancy before the start of therapy.

Treatment without an established diagnosis should be initiated only in patients with rapidly progressive symptoms or those in whom multiple attempts to obtain a tissue diagnosis have been unsuccessful.

Fortunately, relatively noninvasive measures establish the diagnosis in a high percentage of patients with superior vena cava syndrome (SVCS).

Sputum cytologic results are diagnostic in 68% of the cases, whereas biopsy of a palpable supraclavicular node is positive in 87%.

Bronchoscopy has a 60% success rate, while thoracotomy is 100% successful.

Open biopsy is rarely needed for diagnosis. Dosios et al showed that cervical mediastinoscopy and anterior mediastinoscopy are effective in establishing a histologic diagnosis.

Medical Care

The goals of superior vena cava syndrome (SVCS) management are to relieve symptoms and to attempt cure of the primary malignant process. Only a small percentage of patients with a rapid-onset superior vena cava (SVC) obstruction are at risk for life-threatening complications.

Patients with clinical superior vena cava syndrome (SVCS) often gain significant symptomatic improvement from conservative treatment measures, including elevation of the head of the bed and supplemental oxygen.

Emergency treatment is indicated when brain edema, decreased cardiac output, or upper airway edema is present. Corticosteroids and diuretics are often used to relieve laryngeal or cerebral edema, although documentation of their efficacy is questionable.

Radiotherapy has been advocated as a standard treatment for most patients with superior vena cava syndrome (SVCS). It is used as the initial treatment if a histologic diagnosis cannot

be established and the clinical status of the patient is deteriorating; however, recent reviews suggest that superior vena cava syndrome (SVCS) obstruction alone rarely represents an absolute emergency that requires treatment without a specific diagnosis.

The fractionation schedule of radiation usually includes 2-4 large initial fractions of 300-400 cGy, followed by conventional fractionation of 150-200 cGy daily, to a total dose of 3000-5000 cGy. The radiation dose depends on tumor size and radioresponsiveness. The radiation portal should include a 2-cm margin around the tumor.

During irradiation, patients improve clinically before objective signs of tumor shrinkage are evident on chest radiography. Radiation therapy palliates superior vena cava (SVC) obstruction in 70% of patients with lung carcinoma and in more than 95% with lymphoma.

In patients with superior vena cava syndrome (SVCS) secondary to non-small-cell carcinoma of the lung, radiotherapy is the primary treatment. The likelihood of patients benefiting from such therapy is high, but the overall prognosis of these patients is poor.

Chemotherapy may be preferable to radiation for patients with chemosensitive tumors.

In 1983, Maddox and associates reported on 56 patients with small-cell lung cancer who presented with superior vena cava syndrome (SVCS). Correction of superior vena cava syndrome (SVCS) was obtained in 9 (56%) of 16 patients treated with radiation therapy alone, in 23 (100%) of 23 given chemotherapy, and in 5 (83%) of 6 who received combined therapy.²⁷

The most extensive experience in superior vena cava syndrome (SVCS) management secondary to non-Hodgkin lymphoma is reported from the M.D. Anderson cancer center. Patients were treated with chemotherapy alone, chemotherapy combined with radiation therapy, or radiation therapy alone. All patients achieved complete relief of superior vena cava syndrome (SVCS) symptoms within 2 weeks of the institution of any type of treatment. No treatment modality appeared to be superior in achieving clinical improvement.²⁸

When superior vena cava syndrome (SVCS) is due to thrombus around a central venous catheter, patients may be treated with antifibrinolytics (eg, streptokinase, urokinase, recombinant tissue-type plasminogen activator) or anticoagulants (eg, heparin, oral anticoagulants). Removal of the catheter, if possible, is another option, and it should be combined with anticoagulation to avoid embolization.

In a 1988 report, Adelstein et al discuss prophylaxis against embolic events in the presence of a superior vena cava (SVC) obstruction in the management of 25 patients with malignant superior vena cava syndrome (SVCS).

Ten patients were retrospectively reviewed after having been diagnosed clinically without

venography and treated without anticoagulation. Five thromboembolic complications occurred, 2 of which proved fatal.

Fifteen patients were prospectively evaluated by means of angiography and then treated with anticoagulants. Angiographic evidence of intraluminal subclavian vein or superior vena cava (SVC) thrombosis was found in 5 of these patients, and no thromboembolic complications occurred.

Of the 20 patients who were ultimately given anticoagulation therapy, 2 had fatal intracranial hemorrhages.

The authors suggested the need for randomized prospective trials if the role of venography and anticoagulation in this syndrome is to be determined.

Surgical Care

Surgical bypass of the superior vena cava (SVC) may be a useful way to palliate symptoms in carefully selected patients.

Indications to proceed with such procedures are much less clear.

For the most part, these are patients with advanced intrathoracic disease amenable only to palliative therapy (ie, after failure of radiation therapy and chemotherapy).

Patients with benign disease appear to be the best candidates for bypass.

Superior vena cava (SVC) stenting can provide rapid symptomatic relief within few days in most patients with superior vena cava syndrome (SVCS).

Superior vena cava (SVC) stenting may provide relief of severe symptoms for patients while the histological diagnosis of the malignancy causing the obstruction is being actively pursued.

Stenting may also be indicated in patients in whom chemotherapy or radiation has failed.

Some literature recommends stenting as a first-line treatment to be performed early in the management of superior vena cava syndrome (SVCS).

Cases of excimer laser removal of pacemaker leads followed by venoplasty and stenting have been reported.

Medication

The goals of pharmacotherapy are to reduce morbidity and to prevent complications.

Corticosteroids

These agents reduce swelling in patients with cerebral or laryngeal edema.

Dexamethasone (Decadron, Dexasone)

Important therapeutic agent in a number of malignant diseases. Exerts biologic action predominately by binding to glucocorticoid receptor. For symptomatic management in tumor-associated edema.

Thrombolytics

The potential benefits of thrombolytics for the treatment of pulmonary embolism include fast dissolution of physiologically compromising pulmonary emboli, quickened recovery, prevention of recurrent thrombus formation, and rapid restoration of hemodynamic disturbances. For deep vein thrombosis, lysis of the thrombus can prevent pulmonary embolism and permanent pathologic changes, such as venous valvular dysfunction and postphlebitic syndrome.

Urokinase (Abbokinase)

Converts plasminogen to plasmin, which degrades fibrin clots, fibrinogen, and other plasma proteins.

Anticoagulants

In superior vena cava syndrome (SVCS), these agents are used mainly to prevent pulmonary embolism from superior vena cava (SVC) thrombus.

Heparin

Inhibits thrombosis by inactivating activated factor X and inhibiting conversion of prothrombin to thrombin.

Warfarin (Coumadin)

Inhibits synthesis of vitamin K–dependent coagulation factors (factors II, VII, IX, X).

Further Inpatient Care

Admit the patient to the hospital if symptoms of superior vena cava syndrome (SVCS) are moderate to severe and/or when a patient requires the administration of thrombolytic therapy or anticoagulation.

Further Outpatient Care

Instruct patients to use supportive measures, such as elevation of the head of the bed.

Carefully monitor the patient's symptoms and the adverse effects of the administered treatment. Patients should notify the physician immediately if any change in symptoms occurs.

Inpatient & Outpatient Medications

Oxygen supplementation may be provided if needed.

Antiemetics may be provided as needed to prevent nausea and vomiting.

For those patients started on steroids, taper steroids slowly, depending on the patient's condition.

Transfer

Transfer may be required for further diagnostic evaluation and surgical intervention.

Complications

Complications include laryngeal edema, cerebral edema, decreased cardiac output with hypotension, and pulmonary embolism (when an associated thrombus is present).

Prognosis

The survival of patients with superior vena cava syndrome (SVCS) depends mainly on

the course of the underlying disease.

Untreated patients and those not responding to treatment survive approximately 30 days.

TOPIC 12. THROMBOSIS OF MAJOR VEINS.

DEEP VENOUS THROMBOSIS

Introduction of acute deep venous thrombosis

Deep venous thrombosis (DVT) most commonly involves the deep veins of the leg or arm, often resulting in potentially life-threatening emboli to the lungs or debilitating venous alular dysfunction and chronic leg swelling. Deep venous thrombosis (DVT) is also one of the most prevalent medical problems today, with an annual incidence of 117 cases per 100,000. Each year in the United States, more than 200,000 people develop venous thrombosis; of those, 50,000 cases are complicated by pulmonary embolism.¹ Early recognition and appropriate treatment of deep venous thrombosis (DVT) and its complications can save many lives.

Pathophysiology

Over a century ago, Rudolf Virchow described 3 factors that are critically important in the development of venous thrombosis: (1) venous stasis, (2) activation of blood coagulation, and (3) vein damage. Over time, refinements have been made in their description and importance to the development of venous thrombosis. The origin of venous thrombosis is frequently multifactorial, with components of the triad of variable importance in individual patients.

Studies have shown that low flow sites, such as the soleal sinuses, behind venous valve pockets, and at venous confluences, are at most risk for the development of venous thrombi. However, stasis alone is not enough to facilitate the development of venous thrombosis. Experimental ligation of rabbit jugular veins for periods of up to 60 minutes have failed to consistently cause venous thrombosis. Although, patients that are immobilized for long periods of time seem to be at high risk for the development of venous thrombosis, an additional stimulus is required to develop deep venous thrombosis (DVTs).

Mechanical injury to the vein wall appears to provide an added stimulus for venous thrombosis. Hip arthroplasty patients with the associated femoral vein manipulation represent a high-risk group that cannot be explained by just immobilization, with 57% of thrombi originating in the affected femoral vein rather than the usual site of stasis in the calf.⁶

Endothelial injury can convert the normally antithrombogenic endothelium to become prothrombotic by stimulating the production of tissue factor, von Willebrand factor, and fibronectin.

Genetic mutations within the blood's coagulation cascade represent those at highest risk for the development of venous thrombosis (See Table 1).

Table 1. Relative Risk for Venous Thrombosis

Thrombophilic Defect	Relative Risk
Antithrombin deficiency	8-10
Protein C deficiency	7-10
Protein S deficiency	8-10
Factor V Leiden	3-7
Hyperhomocysteinemia	2.5
Anticardiolipin antibodies	3.2

Primary deficiencies of coagulation inhibitors antithrombin, protein C, and protein S are associated with 5-10% of all thrombotic events. Resistance of procoagulant factors to an intact anticoagulation system has also recently been described with the recognition of factor V Leiden mutation, representing 10-65% of patients with deep venous thrombosis (DVT).⁸ In the setting of venous stasis, these factors are allowed to accumulate in thrombosis prone sites, where mechanical vessel injury has occurred, stimulating the endothelium to become prothrombotic.

Components of the Virchow triad are of variable importance in individual patients, but the end result is early thrombus interaction with the endothelium. This interaction stimulates local cytokine production and facilitates leukocyte adhesion to the endothelium, both of which promote venous thrombosis. Depending on the relative balance between activated coagulation and thrombolysis, thrombus propagation occurs.

Over time, thrombus organization begins with the infiltration of inflammatory cells into the clot. This results in a fibroelastic intimal thickening at the site of thrombus attachment in most patients and a fibrous synechia in up to 11%. In many patients, this interaction between vessel wall and thrombus leads to alular dysfunction and overall vein wall fibrosis. Histological examination of vein wall remodeling after venous thrombosis has demonstrated an imbalance in connective tissue matrix regulation and a loss of regulatory venous contractility that contributes to the development of chronic venous insufficiency.

Risk factors

Many factors have been identified as known risk factors for the development of venous thrombosis. The single most powerful risk marker remains a prior history of DVT with up to 25% of acute venous thrombosis occurring in such patients. Pathologically, remnants of previous thrombi are often seen within the specimens of new acute thrombi. However, recurrent thrombosis may actually be the result of primary hypercoagulable states. Abnormalities within the coagulation cascade are the direct result of discrete genetic mutations within the coagulation cascade. Deficiencies of protein C, protein S, or antithrombin III account for approximately 5-10% of all cases of deep venous thrombosis (DVT).

Age has been well studied as an independent risk factor for venous thrombosis development. Although a 30-fold increase in incidence is noted from age 30 to age 80, the effect appears to be multifactorial, with more thrombogenic risk factors occurring in the elderly than in those younger than 40 years. Venous stasis, as seen in immobilized patients and paralyzed limbs, also contributes to the development of venous thrombosis. Autopsy studies parallel the duration of bed rest to the incidence of venous thrombosis, with 15% of patients in those studies dying within 7 days of bedrest to greater than 80% in those dying after 12 weeks.² Within stroke patients, deep venous thrombosis (DVT) is found in 53% of paralyzed limbs, compared with only 7% on the nonaffected side.

Malignancy is noted in up to 30% of patients with venous thrombosis. The thrombogenic mechanisms involve abnormal coagulation, as evidenced by 90% of cancer patients having some abnormal coagulation factors.¹⁸ Chemotherapy may increase the risk of venous thrombosis by affecting the vascular endothelium, coagulation cascades, and tumor cell lysis. The incidence has been shown to increase in those patients undergoing longer courses of

therapy for breast cancer, from 4.9% for 12 weeks of treatment to 8.8% for 36 weeks. Additionally, deep venous thrombosis (DVT) complicates 29% of surgical procedures done for malignancy.

Postoperative venous thrombosis varies depending on a multitude of patient factors, including the type of surgery undertaken. Without prophylaxis, general surgery operations typically have an incidence of deep venous thrombosis (DVT) around 20%, while orthopedic hip surgery can occur in up to 50% of patients. Based on radioactive labeled fibrinogen, about half of lower extremity thrombi develop intraoperatively. Perioperative immobilization, coagulation abnormalities, and venous injury all contribute to the development of surgical venous thrombosis.

Other clinical settings commonly reported as risk factors have also been identified and are shown in Table 2, 3

Table 2. Risk Factors for Venous Thromboembolic Disease

Risk Factor	Odds Ratio
Hospitalization with recent surgery	21.72
Hospitalization without surgery	7.98
Trauma	12.69
Malignancy	6.53
Central venous catheter	5.55
Neurologic disease with paralysis	3.04

Table 3. Risk Factors for Venous Thromboembolism

Acquired	Inherited
Advanced age	Factor V Leiden
Hospitalization/immobilization	Prothrombin 20210A
Hormone replacement therapy and oral contraceptive use	Antithrombin deficiency
	Protein C deficiency
Pregnancy and puerperium	Protein S deficiency
Prior venous thromboembolism	Factor XI elevation
Malignancy	Dysfibrinogenemia
Major surgery	Mixed Etiology
Obesity	Homocysteinemia
Nephrotic syndrome	Factor VII, VIII, IX, XI elevation
Trauma or spinal cord injury	Hyperfibrinogenemia
Long-haul travel (>6 h)	Activated protein C resistance without factor V Leiden
Varicose veins	
Antiphospholipid antibody syndrome	
Myeloproliferative disease	
Polycythemia	

Clinical and diagnostic evaluation

The clinical diagnosis of deep venous thrombosis (DVT) is difficult and fraught with uncertainty. The classic signs and symptoms of deep venous thrombosis (DVT) are those associated with obstruction to venous drainage and include pain, tenderness, and unilateral leg swelling. Other associated nonspecific findings are warmth, erythema, a palpable cord, and pain upon passive dorsiflexion of the foot (Homan sign). However, even with patients with classic symptoms, up to 46% have negative venograms. Furthermore, up to 50% of those with image-documented venous thrombosis lack any specific symptom. Deep venous thrombosis (DVT) simply cannot be diagnosed or excluded based on clinical findings; thus, diagnostic tests must be performed whenever the diagnosis of deep venous thrombosis (DVT) is being considered.

When a patient has deep venous thrombosis (DVT), symptoms may be present or absent, unilateral or bilateral, or mild or severe. Thrombus that does not cause a net venous outflow obstruction is often asymptomatic. Thrombus that involves the iliac bifurcation, the pelvic veins, or the vena cava produces leg edema that is usually bilateral rather than unilateral. High partial obstruction often produces mild bilateral edema that is mistaken for the dependent edema of right-sided heart failure, fluid overload, or hepatic or renal insufficiency.

Severe venous congestion produces a clinical appearance that can be indistinguishable from the appearance of cellulitis. Patients with a warm, swollen, tender leg should be evaluated

for both cellulitis and deep venous thrombosis (DVT) because patients with primary deep venous thrombosis (DVT) often develop a secondary cellulitis, while patients with primary cellulitis often develop a secondary deep venous thrombosis (DVT). Superficial thrombophlebitis, likewise, is often associated with a clinically inapparent underlying DVT.

If a patient is thought to have pulmonary embolism (PE) or has documented PE, the absence of tenderness, erythema, edema, or a palpable cord upon examination of the lower extremities does not rule out thrombophlebitis, nor does it imply a source other than a leg vein. More than two thirds of patients with proven PE lack any clinically evident phlebitis. Nearly one third of patients with proven PE have no identifiable source of deep venous thrombosis (DVT), despite a thorough investigation. Autopsy studies suggest that even when the source is clinically inapparent, it lies undetected within the deep venous system of the lower extremity and pelvis in 90% of cases.

Vascular Lab and Radiologic Evaluation

Duplex Ultrasound

DUS is now the most commonly performed test for the detection of infrainguinal DVT, both above and below the knee, and has a sensitivity and specificity of >95% in symptomatic patients. DUS combines real-time B-mode ultrasound with pulsed Doppler capability. Color flow imaging is useful in more technically difficult examinations, such as in the evaluation of possible calf vein DVT. This combination offers the ability to noninvasively visualize the venous anatomy, detect occluded and partially occluded venous segments, and demonstrate physiologic flow characteristics using a mobile self-contained device.

In the supine patient, normal lower extremity venous flow is phasic (Fig. 1), decreasing with inspiration in response to increased intra-abdominal pressure with the descent of the diaphragm and then increasing with expiration. When the patient is upright, the decrease in intra-abdominal pressure with expiration cannot overcome the hydrostatic column of pressure existing between the right atrium and the calf. Muscular contractions of the calf, along with the one-way venous valves, are then required to promote venous return to the heart. Flow also can be increased by leg elevation or compression and decreased by sudden elevation of intra-abdominal pressure (Valsalva's maneuver). In a venous DUS examination performed with the patient supine, spontaneous flow, variation of flow with respiration, and response of flow to

Valsalva's maneuver are all assessed. However, the primary method of detecting DVT with ultrasound is demonstration of the lack of compressibility of the vein with probe pressure on B-mode imaging. Normally, in transverse section, the vein walls should coapt with pressure. Lack of coaptation indicates thrombus.

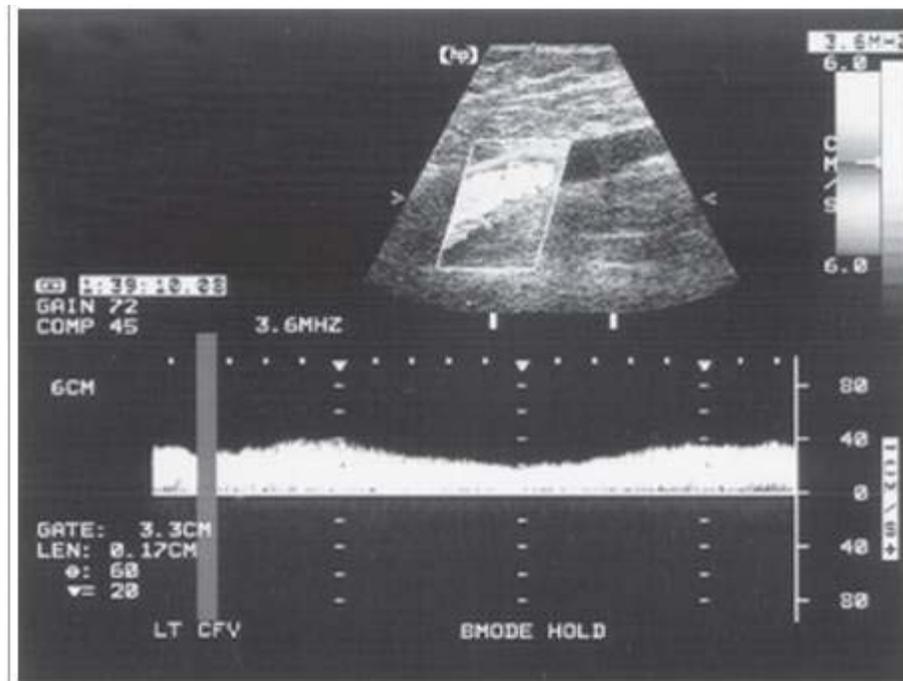

Fig. 1. Duplex ultrasound scan of a normal femoral vein with phasic flow signals.

The examination begins at the ankle and continues proximally to the groin. Each vein is visualized, and the flow signal is assessed with distal and proximal compression. Lower extremity DVT can be diagnosed by any of the following DUS findings: lack of spontaneous flow (Fig. 2), inability to compress the vein (Fig. 3), absence of color filling of the lumen by color flow DUS, loss of respiratory flow variation, and venous distention. Again, lack of venous compression on B-mode imaging is the primary diagnostic variable. Several studies comparing B-mode ultrasound to venography for the detection of femoropopliteal DVT in patients clinically suspected to have DVT report sensitivities of >91% and specificities of >97%. The ability of DUS to assess isolated calf vein DVT varies greatly, with sensitivities ranging from 50 to 93% and specificities approaching 100%.

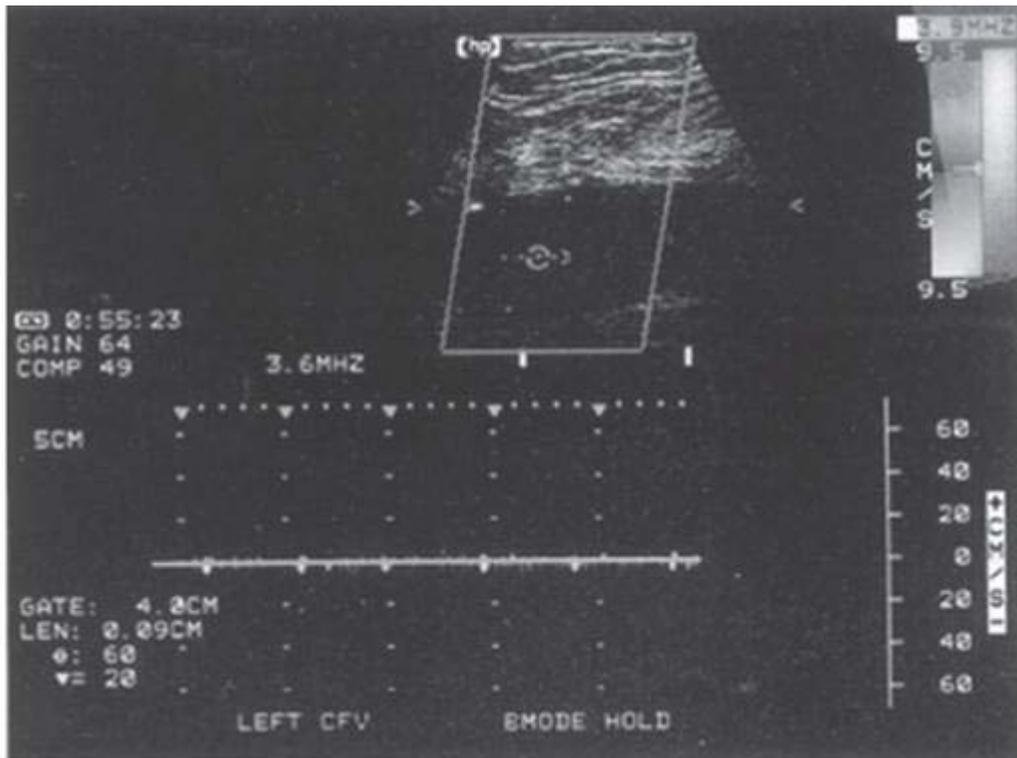

Fig. 2. Duplex ultrasound of a femoral vein containing thrombus demonstrating no flow within the femoral vein

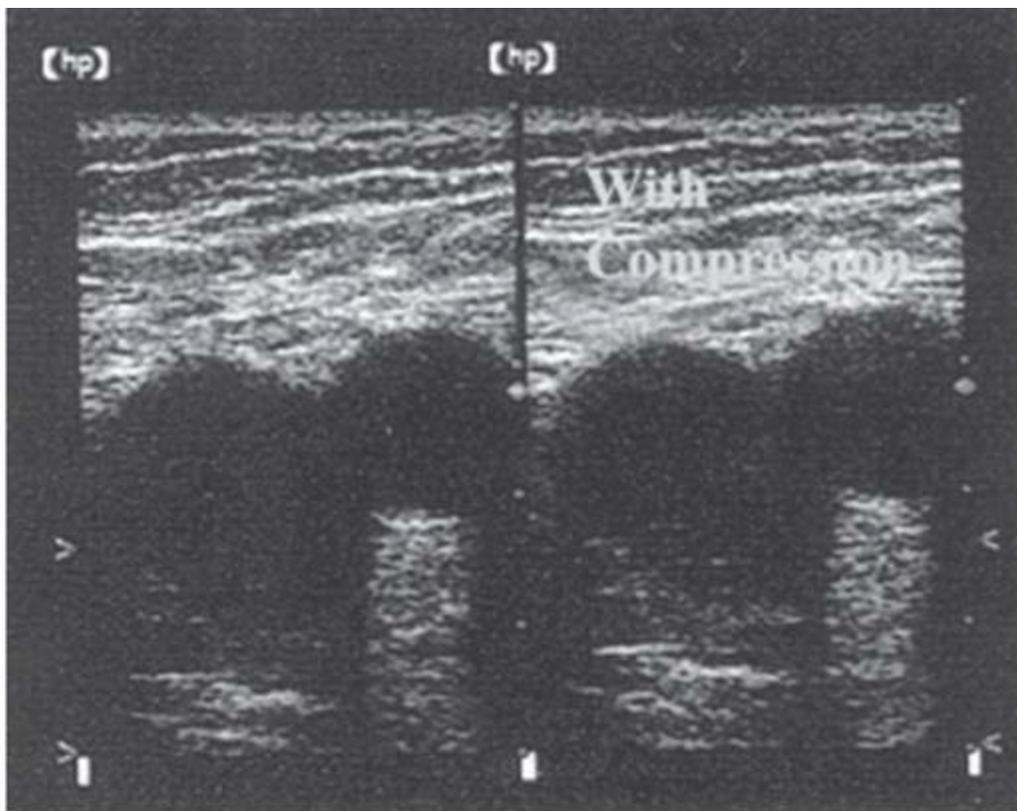

Fig. 3. B-mode ultrasound of the femoral vein in cross-section. The femoral vein does not compress.

not collapse with external compression

Impedance Plethysmography

Impedance plethysmography (IPG) was the primary noninvasive method of diagnosing DVT before the widespread use of DUS but is infrequently used today. IPG is based on the principle that resistance to the flow of electricity between two electrodes, or electrical impedance, occurs as the volume of the extremity changes in response to blood flow. Two pairs of electrodes containing aluminum strips are placed circumferentially around the leg approximately 10 cm apart and a low-level current is delivered to the two outer electrodes. A pneumatic cuff is inflated over the thigh for venous outflow obstruction and then rapidly deflated. Changes in electrical resistance resulting from lower extremity blood volume changes are quantified. IPG is less accurate than DUS for the detection of proximal DVT, with an 83% sensitivity in symptomatic patients. It is a poor detector of calf vein DVT.

Iodine 125 Fibrinogen Uptake

Iodine 125 fibrinogen uptake (FUT) is a seldom used technique that involves IV administration of radioactive fibrinogen and monitoring for increased uptake in fibrin clots. An increase of 20% or more in one area of a limb indicates an area of thrombus.²³ FUT can detect DVT in the calf, but high background radiation from the pelvis and the urinary tract limits its ability to detect proximal DVT. It also cannot be used in an extremity that has recently undergone surgery or has active inflammation. In a prospective study, FUT had a sensitivity of 73% and specificity of 71% for identification of DVT in a group of symptomatic and asymptomatic patients. Currently, FUT is primarily a research tool of historic interest.

Venography

Venography is the most definitive test for the diagnosis of DVT in both symptomatic and asymptomatic patients. It is the gold standard to which other modalities are compared. This procedure involves placement of a small catheter in the dorsum of the foot and injection of a radiopaque contrast agent. Radiographs are obtained in at least two projections. A positive study result is failure to fill the deep system with passage of the contrast medium into the

superficial system or demonstration of discrete filling defects (Fig. 4). A normal study result virtually excludes the presence of DVT. In a study of 160 patients with a normal venogram followed for 3 months, only two patients (1.3%) subsequently developed DVT and no patients experienced symptoms of PE.

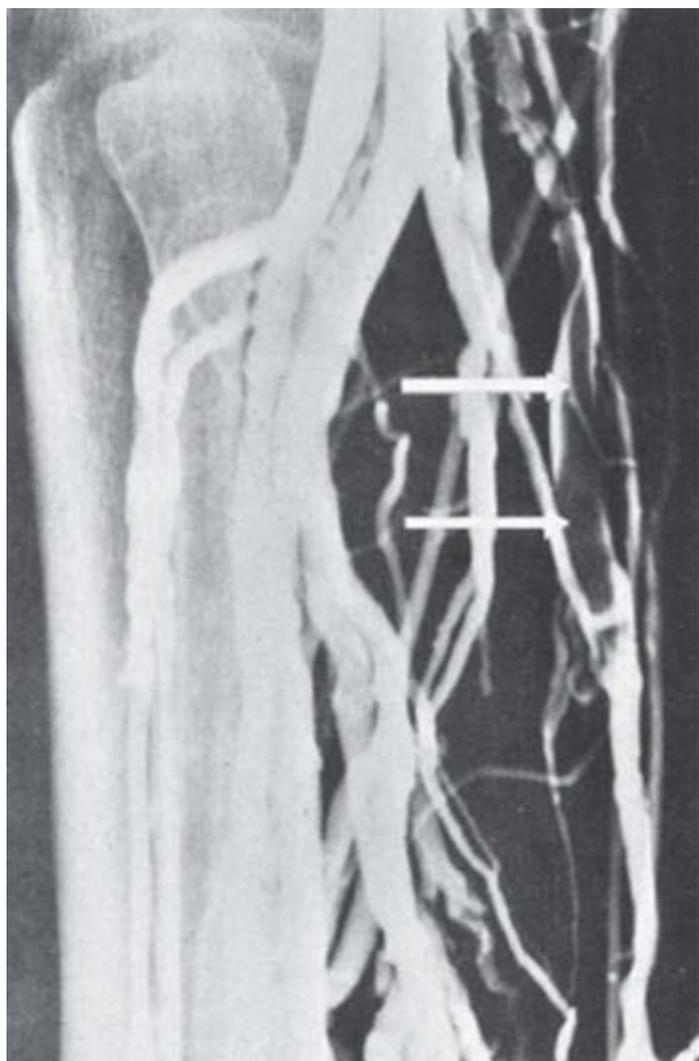

Fig. 4. Venogram showing a filling defect in the popliteal vein (*arrows*).

Venography is not routinely used for the evaluation of lower extremity DVT because of the associated complications discussed previously. Currently, venography is reserved for imaging before operative venous reconstruction and catheter-based therapy. It does, however, remain the procedure of choice in research studies evaluating methods of prophylaxis for DVT.

Laboratory analysis has also been used in aiding the diagnosis of venous thrombosis. D-dimers are degradation products of cross-linked fibrin by plasmin that are detected by diagnostic assays. Although highly sensitive, up to 97%, elevated levels are not specific with

rates as low as 35%.²⁷ Many other clinical situations can result in elevated D-dimer levels, including infection, trauma, postoperative states, and malignancy.²⁸ Additional blood work should include coagulation studies to evaluate for a hypercoagulable state, if clinically indicated. A prolonged prothrombin time or activated partial thromboplastin time does not imply a lower risk of new thrombosis. Progression of deep venous thrombosis (DVT) and PE can occur despite full therapeutic anticoagulation in 13% of patients.

Treatment

Once the diagnosis of VTE has been made, antithrombotic therapy should be initiated promptly. If clinical suspicion for VTE is high, it may be prudent to start treatment while the diagnosis is being objectively confirmed. The theoretic goals of VTE treatment are the prevention of mortality and morbidity associated with PE and the prevention of the postphlebotic syndrome. However, the only proven benefit of anticoagulant treatment for DVT is the prevention of death from PE. Treatment regimens may include antithrombotic therapy, vena caval interruption, catheter-directed or systemic thrombolytic therapy, and operative thrombectomy.

Antithrombotic Therapy

Antithrombotic therapy may be initiated with IV or SC unfractionated heparin, SC low molecular weight heparin, or SC fondaparinux (a synthetic pentasaccharide). This initial therapy usually is continued for at least 5 days, while oral vitamin K antagonists are being simultaneously administered. The initial therapy typically is discontinued when the international normalized ratio (INR) is ≥ 2.0 for 24 hours.

Unfractionated heparin (UFH) binds to antithrombin via a specific 18-saccharide sequence, which increases its activity over 1000-fold. This antithrombin-heparin complex primarily inhibits factor IIa (thrombin) and factor Xa and, to a lesser degree, factors IXa, XIa, and XIIa. In addition, UFH also binds to tissue factor pathway inhibitor, which inhibits the conversion of factor X to Xa, and factor IX to IXa. Finally, UFH catalyzes the inhibition of thrombin by heparin cofactor II via a mechanism that is independent of antithrombin.

UFH therapy is most commonly administered with an initial IV bolus of 80 units/kg or 5000 units. Weight-based UFH dosages have been shown to be more effective than standard fixed boluses in rapidly achieving therapeutic levels. The initial bolus is followed by a

continuous IV drip, initially at 18 units/kg per hour or 1300 units per hour. The half-life of IV UFH ranges from 45 to 90 minutes and is dose dependent. The level of antithrombotic therapy should be monitored every 6 hours using the activated partial thromboplastin time (aPTT), with the goal range of 1.5 to 2.5 times control values. This should correspond with plasma heparin anti-Xa activity levels of 0.3 to 0.7 IU/mL.

Initial anticoagulation with UFH may be administered SC, although this route is less commonly used. Adjusted-dose therapeutic SC UFH is initiated with 17,500 units, followed by 250 units/kg twice daily, and dosing is adjusted to an aPTT goal range similar to that for IV UFH. Fixed-dose unmonitored SC UFH is started with a bolus of 333 units/kg, followed by 250 units/kg twice daily.

Hemorrhage is the primary complication of UFH therapy. The rate of major hemorrhage (fatal, intracranial, retroperitoneal, or requiring transfusion of >2 units of packed red blood cells) is approximately 5% in hospitalized patients undergoing UFH therapy (1% in medical patients and 8% in surgical patients).²⁷ For patients with UFH-related bleeding complications, cessation of UFH is required, and anticoagulation may be reversed with protamine sulfate. Protamine sulfate binds to UFH and forms an inactive salt compound. Each milligram of protamine neutralizes 90 to 115 units of heparin, and the dosage should not exceed 50 mg IV over any 10-minute period. Side effects of protamine sulfate include hypotension, pulmonary edema, and anaphylaxis. Patients with prior exposure to protamine-containing insulin (NPH) and patients with allergy to fish may have an increased risk of hypersensitivity, although no direct relationship has been established. The protamine infusion should be terminated if any side effects occur.

In addition to hemorrhage, heparin also has unique complications. Heparin-induced thrombocytopenia (HIT) results from heparin-associated antiplatelet antibodies (HAAs) directed against platelet factor 4 complexed with heparin. HIT occurs in 1 to 5% of patients being treated with heparin. In patients with repeat heparin exposure (such as vascular surgery patients), the incidence of HAAb may be as high as 21%. HIT occurs most frequently in the second week of therapy and may lead to disastrous venous or arterial thrombotic complications. Therefore, platelet counts should be monitored periodically in patients receiving continuous heparin therapy. All forms of heparin should be stopped if there is a high clinical suspicion or confirmation of HIT [usually accompanied by an unexplained thrombocytopenia (<100,000/

L) or platelet count decrease of 30 to 50%]. Fortunately, direct thrombin inhibitors (recombinant hirudin, argatroban, bivalirudin) now are available as alternative antithrombotic

agents (see later). Another complication of prolonged high-dose heparin therapy is osteopenia, which results from impairment of bone formation and enhancement of bone resorption by heparin.

Low molecular weight heparins (LMWHs) are derived from the depolymerization of porcine UFH. Like UFH, LMWHs bind to antithrombin via a specific pentasaccharide sequence to expose an active site for the neutralization of factor Xa. However, LMWHs lack the sufficient number of additional saccharide units (18 or more), which results in less inactivation of thrombin (factor IIa). In comparison to UFH, LMWHs have increased bioavailability (>90% after SC injection), longer half-lives (approximately 4 to 6 hours), and more predictable elimination rates. Weight-based once- or twice-daily SC LMWH injections, for which no monitoring is needed, provide a distinct advantage over continuous IV infusions of UFH for treatment of VTE.

Most patients who receive therapeutic LMWH do not require monitoring. Patients who do require monitoring include those with significant renal insufficiency or failure, pediatric patients, obese patients of >120 kg, and patients who are pregnant. Monitoring may be performed using anti-Xa activity assays. However, the therapeutic anti-Xa goal range will depend on the type of LMWH and the frequency of dosing. Numerous LMWHs are commercially available. The various preparations differ in their anti-Xa and anti-IIa activities, and the treatment dosing for one LMWH cannot be extrapolated for use with another. The action of LMWHs may be partially reversed (approximately 60%) with protamine sulfate.

Numerous well-designed trials comparing SC LMWH with IV and SC UFH for the treatment of DVT have been critically evaluated in several meta-analyses. The more recent studies demonstrate a decrease in thrombotic complications, bleeding, and mortality with LMWHs. LMWHs also are associated with a decreased rate of HAAb formation and HIT (<2%) compared with UFH (at least in prophylactic doses). However, patients with established HIT should not subsequently receive LMWHs due to significant rates of cross reactivity. A major benefit of LMWHs is the ability to treat patients with VTE as outpatients. In a randomized study comparing IV UFH and the LMWH nadroparin calcium, there was no significant difference in recurrent thromboembolism (8.6% for UFH vs. 6.9% for LMWH) or major bleeding complications (2.0% for UFH vs. 0.5% for LMWH). There was a 67% reduction in mean days in the hospital for the LMWH group.

A patient with VTE should meet several criteria before receiving outpatient LMWH therapy. First, the patient should not require hospitalization for any associated conditions. The patient should not require monitoring of the LMWH therapy (which is necessary in patients

with severe renal insufficiency, pediatric patients, obese patients, and pregnant patients). The patient should be hemodynamically stable with a low suspicion of PE and have a low bleeding risk. An established outpatient system to administer LMWH and warfarin, as well as to monitor for recurrent VTE and bleeding complications, should be present. In addition, the patient's symptoms of pain and edema should be controllable at home.

Fondaparinux currently is the only synthetic pentasaccharide that has been approved by the U.S. Food and Drug Administration (FDA) for the initial treatment of DVT and PE. Its five-polysaccharide sequence binds and activates antithrombin, causing specific inhibition of factor Xa. In two large noninferiority trials, fondaparinux was compared with the LMWH enoxaparin for the initial treatment of DVT and with IV UFH for the initial treatment of PE. The rates of recurrent VTE ranged from 3.8 to 5%, with rates of major bleeding of 2 to 2.6%, for all treatment arms. The drug is administered SC once daily with a weight-based dosing protocol: 5 mg, 7.5 mg, or 10 mg for patients weighing <50 kg, 50 to 100 kg, or >100 kg, respectively. The half-life of fondaparinux is approximately 17 hours in patients with normal renal function. There are rare case reports of fondaparinux-induced thrombocytopenia.

Direct-thrombin inhibitors (DTIs) include recombinant hirudin, argatroban, and bivalirudin. These antithrombotic agents bind to thrombin, inhibiting the conversion of fibrinogen to fibrin as well as thrombin-induced platelet activation. These actions are independent of antithrombin. The direct thrombin inhibitors should be reserved for (a) patients in whom there is a high clinical suspicion or confirmation of HIT, and (b) patients who have a history of HIT or test positive for heparin-associated antibodies. In patients with established HIT, DTIs should be administered for at least 7 days, or until the platelet count normalizes. Warfarin may then be introduced slowly, overlapping therapy with a DTI for at least 5 days.⁴¹ Because bivalirudin is approved primarily for patients with or without HIT who undergo percutaneous coronary intervention, it is not discussed here in further detail.

Commercially available hirudin is manufactured using recombinant DNA technology. It is indicated for the prophylaxis and treatment of patients with HIT. In patients with normal renal function, recombinant hirudin is administered in an IV bolus dose of 0.4 mg/kg, followed by a continuous IV infusion of 0.15 mg/kg per hour. The half-life ranges from 30 to 60 minutes. The aPTT is monitored, starting approximately 4 hours after initiation of therapy, and dosage is adjusted to maintain an aPTT of 1.5 to 2.5 times the laboratory normal value. The less commonly used ecarin clotting time is an alternative method of monitoring. Because recombinant hirudin is eliminated via renal excretion, significant dosage adjustments are required in patients with renal insufficiency.

Argatroban is indicated for the prophylaxis and treatment of thrombosis in HIT. It also is approved for patients with, or at risk for, HIT who undergo percutaneous coronary intervention. Antithrombotic prophylaxis and therapy are initiated with a continuous IV infusion of 2 g/kg per minute, without the need for a bolus. The half-life ranges from 39 to 51 minutes, and the dosage is adjusted to maintain an aPTT of 1.5 to 3 times normal. Large initial boluses and higher rates of continuous infusion are reserved for patients with coronary artery thrombosis and myocardial infarction. In these patients, therapy is monitored using the activated clotting time. Argatroban is metabolized by the liver, and the majority is excreted via the biliary tract. Significant dosage adjustments are needed in patients with hepatic impairment. There is no reversal agent for argatroban.

Vitamin K antagonists, which include warfarin and other coumarin derivatives, are the mainstay of long-term antithrombotic therapy in patients with VTE. Warfarin inhibits the γ -carboxylation of vitamin K–dependent procoagulants (factors II, VII, IX, X) and anticoagulants (proteins C and S), which results in the formation of less functional proteins. Warfarin usually requires several days to achieve its full effect, because normal circulating coagulation proteins must first undergo their normal degradation. Factors X and II have the longest half-lives, in the range of 36 and 72 hours, respectively. In addition, the steady-state concentration of warfarin is usually not reached for 4 to 5 days.

Warfarin therapy usually is monitored by measuring the INR, calculated using the following equation:

$$\text{INR} = \left(\frac{\text{patient prothrombin time/laboratory normal prothrombin time}}{\text{ISI}} \right)^{\text{ISI}}$$

where *ISI* is the international sensitivity index. The ISI describes the strength of the thromboplastin that is added to activate the extrinsic coagulation pathway. The therapeutic target INR range is usually 2.0 to 3.0, but the response to warfarin is variable and depends on liver function, diet, age, and concomitant medications. In patients receiving anticoagulation therapy without concomitant thrombolysis or venous thrombectomy, the vitamin K antagonist may be started on the same day as the initial parenteral anticoagulant, usually at doses ranging from 5 to 10 mg. Smaller initial doses may be needed in older and malnourished patients, in those with liver disease or congestive heart failure, and in those who have recently undergone major surgery.

The recommended duration of warfarin antithrombotic therapy is increasingly being

stratified based on whether the DVT was provoked or unprovoked, whether it was the first or a recurrent episode, where the DVT is located, and whether malignancy is present. Current American College of Chest Physicians (ACCP) recommendations for duration of warfarin therapy are summarized in Table 24-3. In patients with proximal DVT, several randomized clinical trials have demonstrated that shorter-term antithrombotic therapy (4 to 6 weeks) is associated with a higher rate of recurrence than 3 to 6 months of anticoagulation. In these trials, most of the patients with transient risk factors had a low rate of recurrent VTE; most of the recurrences were in patients with continuing risk factors. These studies support the ACCP recommendation that 3 months of anticoagulation is sufficient to prevent recurrent VTE in patients whose DVT occurred around the time of a transient risk factor (e.g., hospitalization, orthopedic or major general surgery).

Table 4. Summary of American College of Chest Physicians Recommendations Regarding Duration of Long-Term Antithrombotic Therapy for Deep Vein Thrombosis (DVT)

Clinical Subgroup	Antithrombotic Treatment Duration
First episode DVT/transient risk	VKA for 3 mo
First episode DVT/unprovoked	VKA for at least 3 mo
	Consider for long-term therapy if:
	• Proximal DVT
	• Minimal bleeding risk
	• Stable coagulation monitoring
Distal DVT/unprovoked	VKA for 3 mo
Second episode DVT/unprovoked	VKA long-term therapy
DVT and cancer	LMWH 3–6 mo
	Then VKA or LMWH indefinitely until cancer resolves

LMWH = low molecular weight heparin; VKA = vitamin K antagonist.

Antithrombotic therapy for venous thromboembolic disease: American College of Chest Physicians Evidence-Based Clinical Practice Guidelines (8th edition). *Chest* 133:454S, 2008.

In contrast to patients with thrombosis related to transient risk factors, patients with idiopathic VTE are much more likely to develop recurrence (rates as high as 40% at 10 years). In this latter group of patients, numerous clinical trials have compared 3 to 6 months of anticoagulation therapy with extended-duration warfarin therapy, both at low intensity (INR of 1.5 to 2.0) and at conventional intensity (INR of 2.0 to 3.0). In patients with idiopathic DVT, extended-duration antithrombotic therapy is associated with a relative reduction in the rate of recurrent VTE by 75% to >90%. In addition, conventional-intensity warfarin reduces the risk

even further compared with low-intensity warfarin (0.7 events per 100 person-years vs. 1.9 events per 100 person-years), but the rate of bleeding complications is no different.

In patients with VTE in association with a hypercoagulable condition, the optimal duration of anticoagulation therapy is influenced more by the clinical circumstances at the time of the VTE (idiopathic vs. secondary) than by the actual presence or absence of the more common thrombophilic conditions. In patients with VTE related to malignancy, increasing evidence suggests that longer-term therapy with LMWH (up to 6 months) is associated with a lower VTE recurrence rate than treatment using conventional vitamin K antagonists.

The primary complication of warfarin therapy is hemorrhage, and the risk is related to the magnitude of INR prolongation. Depending on the INR and the presence of bleeding, warfarin anticoagulation may be reversed by (a) omitting or decreasing subsequent dosages, (b) administering oral or parenteral vitamin K, or (c) administering fresh-frozen plasma, prothrombin complex concentrate, or recombinant factor VIIa. Warfarin therapy rarely may be associated with the development of skin necrosis and limb gangrene. These conditions occur more commonly in women (4:1), and the most commonly affected areas are the breast, buttocks, and thighs. This complication, which usually occurs in the first days of therapy, is occasionally, but not exclusively, associated with protein C or S deficiency and malignancy. Patients who require continued anticoagulation may restart low-dose warfarin (2 mg) while receiving concomitant therapeutic heparin. The warfarin dosage is then gradually increased over a 1- to 2-week period.

Systemic and Catheter-Directed Thrombolysis

Patients with extensive proximal DVT may benefit from systemic thrombolysis or catheter-directed thrombolysis, which can potentially reduce acute symptoms more rapidly than anticoagulation alone. These techniques also may decrease the development of postthrombotic syndrome. Several thrombolysis preparations are available, including streptokinase, urokinase, alteplase (recombinant tissue plasminogen activator), reteplase, and tenecteplase. All these agents share the ability to convert plasminogen to plasmin, which leads to the degradation of fibrin. They differ with regard to their half-lives, their potential for inducing fibrinogenolysis (generalized lytic state), their potential for antigenicity, and their FDA-approved indications for use.

Streptokinase is purified from beta-hemolytic *Streptococcus* and is approved for the treatment of acute myocardial infarction, PE, DVT, arterial thromboembolism, and occluded

central lines and arteriovenous shunts. It is not specific for fibrin-bound plasminogen, however, and its use is limited by its significant rates of antigenicity. Fevers and shivering occur in 1 to 4% of patients. Urokinase is derived from human neonatal kidney cells, grown in tissue culture. Currently, it is only approved for lysis of massive PE or PE associated with unstable hemodynamics. Alteplase, reteplase, and tenecteplase all are recombinant variants of tissue plasminogen activator. Alteplase is indicated for the treatment of acute myocardial infarction, acute ischemic stroke, and acute massive PE. However, it often is used for catheter-directed thrombolysis of DVT. Reteplase and tenecteplase are indicated only for the treatment of acute myocardial infarction.

Systemic thrombolysis was evaluated in numerous older prospective and randomized clinical trials, and its efficacy was summarized in a recent Cochrane Review. In 12 studies involving over 700 patients, systemic thrombolysis was associated with significantly more clot lysis [relative risk (RR) 0.24 to 0.37] and significantly less postthrombotic syndrome (RR 0.66). However, venous function was not significantly improved. In addition, more bleeding complications did occur (RR 1.73), but the incidence appears to have decreased in later studies, probably due to improved patient selection.

In an effort to minimize bleeding complications and increase efficacy, catheter-directed thrombolytic techniques have been developed for the treatment of symptomatic DVT. With catheter-directed therapy, venous access may be achieved through percutaneous catheterization of the ipsilateral popliteal vein, retrograde catheterization through the contralateral femoral vein, or retrograde cannulation from the internal jugular vein. Multi-side-hole infusion catheters, with or without infusion wires, are used to deliver the lytic agent directly into the thrombus.

The efficacy of catheter-directed urokinase for the treatment of symptomatic lower extremity DVT has been reported in a large multicenter registry. Two hundred twenty-one patients with iliofemoral DVT and 79 patients with femoropopliteal DVT were treated with catheter-directed urokinase for a mean of 53 hours. Complete lysis was seen in 31% of the limbs, 50 to 99% lysis in 52% of the limbs, and <50% lysis in 17%. Overall, 1-year primary patency was 60%. Patency was higher in patients with iliofemoral DVT than in patients with femoropopliteal DVT (64% vs. 47%, $P < .01$). In addition, patients with acute symptoms (≤ 10 days) had a greater likelihood of complete lysis (34%) than patients with chronic symptoms (> 10 days; 19%). Major bleeding occurred in 11%, but neurologic involvement and mortality were rare (both 0.4%). Adjunctive stent placement to treat residual stenosis and/or short

segment occlusion was required in 103 limbs.

One small randomized trial and numerous other retrospective studies have demonstrated similar rates of thrombolysis, with some also showing improved valve preservation and quality of life. Combining thrombolysis with percutaneous thrombus fragmentation and extraction has the added benefit of decreasing the infusion time, the hospital stay, and the overall cost of treatment. These studies, as well as the current ACCP guidelines, suggest that catheter-directed thrombolysis (with adjunctive angioplasty, venous stenting, and pharmacomechanical fragmentation and extraction) may be useful in selected patients with extensive iliofemoral DVT. Patients should have a recent onset of symptoms (<14 days), good functional status, decent life expectancy, and low bleeding risk.

Inferior Vena Caval Filters

Since the introduction of the Kimray-Greenfield filter in the United States in 1973, numerous vena caval filters have been developed. Although the designs are variable, they all prevent pulmonary emboli, while allowing continuation of venous blood flow through the IVC. Early filters were placed surgically through the femoral vein. Currently, less invasive techniques allow percutaneous filter placement through a femoral vein, internal jugular vein, or small peripheral vein under fluoroscopic or ultrasound guidance. Complications associated with IVC filter placement include insertion site thrombosis, filter migration, erosion of the filter into the IVC wall, and IVC thrombosis. The rate of fatal complications is <0.12%.

Placement of an IVC filter is indicated for patients who develop recurrent DVT (significant propagation of the original thrombus or proximal DVT at a new site) or PE despite adequate anticoagulation therapy and for patients with pulmonary hypertension who experience recurrent PE. In patients who receive IVC filters for these indications, therapeutic anticoagulation should be continued. The duration of anticoagulation is determined by the underlying VTE and not by the presence of the IVC filter itself. Practically speaking, however, many patients who require an IVC filter for recurrent VTE are the same ones who would benefit most from indefinite anticoagulation. The other major indication for placement of an IVC filter is a contraindication to, or complication of, anticoagulation therapy in the presence of an acute proximal DVT. In patients who are not able to receive anticoagulants due to recent surgery or trauma, the clinician should continually reassess if antithrombotic agents may be

started safely at a later date. Even some patients who develop anticoagulation-associated bleeding complications may be able to restart therapy at a lower intensity of anticoagulation later in the hospital course. As before, the clinical circumstances surrounding the VTE should determine the duration of anticoagulation.

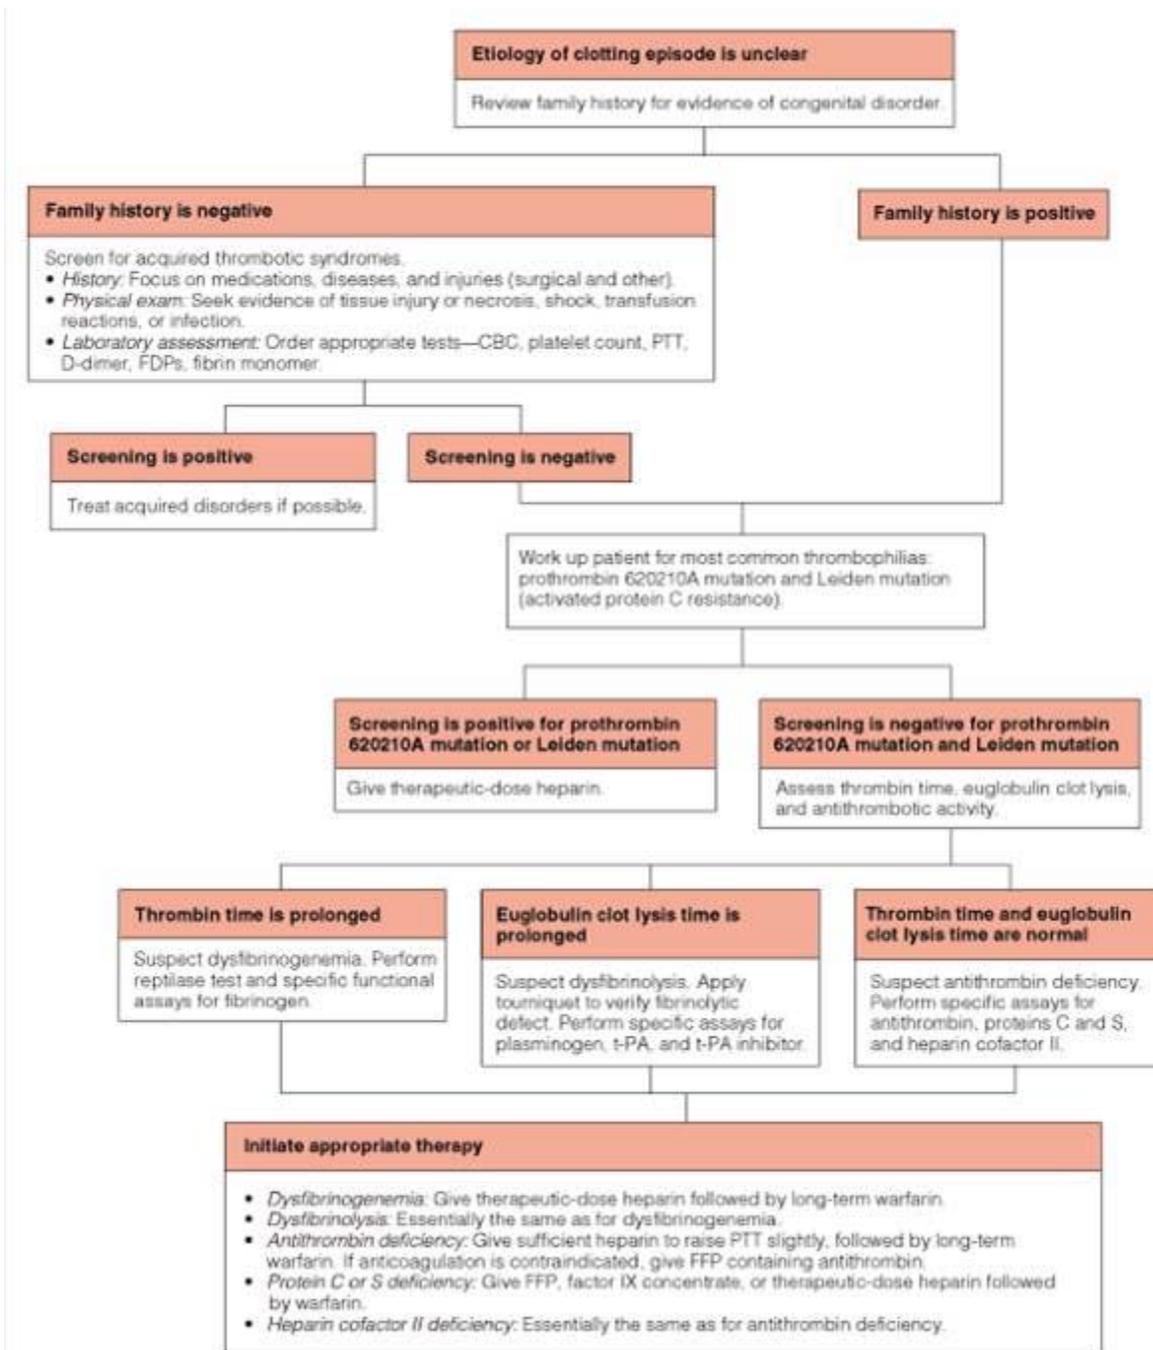

Placement of permanent IVC filters has been evaluated as an adjunct to routine anticoagulation in patients with proximal DVT. In this study, routine IVC filter placement did not prolong early or late survival in patients with proximal DVT but did decrease the rate of PE (hazard ratio, 0.22; 95% confidence interval, 0.05 to 0.90). An increased rate of recurrent DVT was seen in patients with IVC filters (hazard ratio, 1.87; 95% confidence interval, 1.10 to 3.20). More controversial indications for IVC filter placement include prophylaxis against PE in patients receiving catheter-directed thrombolysis and in high-risk patients without established DVT or PE.

Hypercoagulability States

Certain patients seem to have a tendency to clot spontaneously. So-called hypercoagulability states were long thought to exist, but they were difficult to document except on clinical grounds. Currently, however, these clotting tendencies are better understood, thanks in large part to recognition of the role of antithrombins. If an antithrombin deficiency exists and clotting goes unchecked, activation of a clotting cascade could theoretically progress to clotting throughout the entire vasculature. Another important development was the recognition that deficiencies of certain natural clot-removing substances in the blood may lead to a clinical thrombotic tendency. Both types of deficiency can be either acquired or congenital.

Screening

When the etiology of a clotting episode is unclear, the family history should be reviewed for evidence of a congenital disorder. Even if the history is negative, the patient should be screened for both acquired and congenital disorders (table 6).

Acquired Clotting Conditions

Screening for acquired clotting conditions [see Table 7] is based on the history, physical examination, and laboratory assessment. The history should include medications, diseases, and surgical procedures or other injuries. Examination may disclose causes of hypercoagulability. Soft tissue injury, for example, is a potent activator of the coagulation system. If the injury is severe enough, it may be capable of causing a severe acquired coagulopathy. The problem is usually obvious, but on occasion, detailed study may be necessary to identify tissue damage or ischemic injury to bowel or extremities. Hypovolemia—especially hypovolemic

shock markedly reduces clotting time: blood from a patient in profound shock may clot instantaneously in the syringe as it is being drawn. The breakdown of red cells in a hemolytic transfusion reaction can cause clotting. Severe infection, especially from gram-negative organisms, is a potent activator of coagulation.

Table 7. Etiology of Acquired Hypercoagulability

Tissue and cellular damage
Shock
Trauma
Surgery
Tissue necrosis
Transfusion necrosis
Drugs
Estrogens
Drug reactions and interactions
Heparin platelet antibody
Warfarin
Disease
Blood dyscrasias
Cancer
Diabetes
Homocystinuria
Hyperlipidemia
Presence of lupuslike anticoagulant
Severe infection
Pregnancy

Of the acquired hypercoagulability syndromes, Trousseau syndrome is a particularly important condition for surgeons to recognize because it occurs in the surgical population (cancer patients) and must be treated with heparin (it is unresponsive to warfarin). It occurs when an adenocarcinoma secretes a protein recognized by the body as tissue factor, resulting in multiple episodes of venous thromboembolism over time (migratory thrombophlebitis). Simple depletion of vitamin K-dependent factors is ineffective. Patients should receive therapeutic-dose heparin indefinitely or until the cancer is brought into remission.

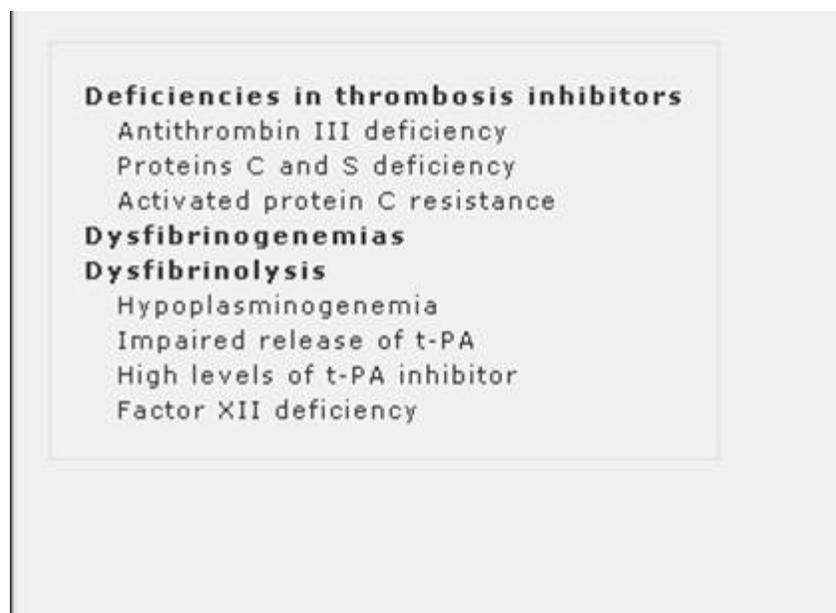

Laboratory screening may facilitate diagnosis. A complete blood count may document the presence of polycythemia or leukemia. Thrombocytopenia may be a manifestation of a hypercoagulable disorder, and thrombocytopenia after the administration of heparin raises the possibility of intravascular platelet aggregation. A prolonged aPTT is suggestive of lupuslike anticoagulant. Increased levels of D-dimers, fibrin degradation products (FDPs), or fibrin

monomers in the plasma may reflect low-grade intravascular coagulation.

Congenital Clotting Conditions

Congenital clotting tendencies can result from deficiencies in inhibitors of thrombosis (antithrombin, proteins C and S, and possibly heparin cofactor II), dysfibrinogenemias, or dysfibrinolysis [see Table 8]. Most congenital clotting defects are transmitted as an autosomal dominant trait. A negative family history does not preclude inherited thrombophilia, because the defects have a low penetrance, and fresh mutations may have occurred.

Table 8. Congenital Clotting Disorders

Deficiencies in thrombosis inhibitors
Antithrombin III deficiency
Proteins C and S deficiency
Activated protein C resistance
Dysfibrinogenemias
Dysfibrinolysis
Hypoplasminogenemia
Impaired release of t-PA
High levels of t-PA inhibitor
Factor XII deficiency

INITIAL LABORATORY ASSESSMENT

Initial evaluation of a patient with an unexplained thrombotic episode should be directed at the most common causes of hypercoagulability. Acquired causes of clotting are more commonly seen by surgeons than congenital causes and therefore must be excluded first. If a clotting disorder is determined to be congenital, a laboratory workup should be undertaken. Several of the relevant assays "specifically, the functional assays" should be performed after the acute phase of the disorder has passed. If they are performed during the acute phase, levels of several antithrombotics (e.g., antithrombin and proteins C and S) will be misleadingly low not because deficiencies of these substances caused the underlying thrombotic process but because they were consumed in that process.

Specific Causes Of Thrombotic Tendency

The most common congenital causes of accelerated clotting are mutations of prothrombin (prothrombin G20210A mutation) and factor V (Leiden mutation, or activated protein C resistance). The prevalence of each of these ranges from 1% to 5% in the general population and may be much higher in specific ethnic subpopulations.¹ Each mutation may be identified conclusively by means of polymerase chain reaction (PCR) techniques. Detection of these mutations, unlike assays for antithrombin and proteins C and S, is not dependent on the patient's current inflammatory state. It must be remembered that the presence of one of these mutations, especially in the heterozygous form, does not imply that it is the sole cause of thrombosis. In many patients, a second precipitating factor must be present for the pathologic genetic thrombotic potential to be manifested.

Prothrombin G20210A Mutation

The prothrombin G20210A mutation is known to involve a single amino acid substitution in the prothrombin gene, but precisely how this increases the risk of venous thromboembolism is unclear. The one apparent manifestation of the mutation is a 15% to 40% increase in circulating prothrombin. Regardless of the mechanism at work, patients who are at least heterozygous for the trait are at two- to sixfold greater risk for venous thromboembolism than those without the mutation.

Resistance to Activated Protein C (Factor V Leiden)

Resistance of human clotting factors to inactivation by activated protein C is believed to be the most common inherited procoagulant disorder.¹¹⁴ Normally, activated factor V is degraded by activated protein C in the presence of membrane surface as part of normal regulation of thrombosis. Activated protein C resistance is caused by a single substitution mutation in the factor V gene, which is passed in an autosomal dominant fashion. The mutant factor V that results, termed factor V Leiden, is resistant to inactivation by activated protein C and thus has a greater ability to activate thrombin and accelerate clotting.

Two techniques are commonly used to diagnose this disorder. The first is a functional assay that compares a standard aPTT to one performed in the presence of exogenous activated

protein C. If the latter aPTT does not exhibit significant prolongation, the patient is probably resistant to activated protein C. The results of this assay must be interpreted with caution if the patient is still in the acute phase of the illness. The second technique, which is more reliable, involves direct detection of the mutation via PCR analysis of DNA.

Antithrombin Deficiency

Antithrombin (once termed antithrombin III) is a 65 kd protein that decelerates the coagulation system by inactivating activated factors, primarily factor Xa and thrombin but also factors XII, XI, and IX. Antithrombin therefore acts as a scavenger of activated clotting factors. Its activity is enhanced 100-fold by the presence of heparans on the endothelial surface and 1,000-fold by administration of exogenous heparin.

Congenital antithrombin deficiency occurs in approximately 0.01% to 0.05% of the general population and 2% to 4% of patients with venous thrombosis. The trait is passed on as an autosomal dominant trait, with the heterozygous genotype being incompatible with life. Antithrombin-deficient patients are at increased risk for thromboembolism when their antithrombin activity falls below 70% of normal.

Patients with congenital antithrombin deficiency frequently present after a stressful event. They usually have DVT but sometimes have PE. If anticoagulation is not contraindicated, the treatment of choice is heparin at a dosage sufficient to raise the aPTT to the desired level, followed by warfarin. If anticoagulation is contraindicated (as it is during the peripartum period), antithrombin concentrate should be given to raise the antithrombin activity to 80% to 120% of normal during the period when anticoagulants cannot be given.

Acquired antithrombin deficiency is a well-recognized entity. In most patients undergoing severe systemic stress, antithrombin levels fall below normal. Patients with classic risk factors for venous thromboembolism tend to have the lowest levels.

Protein C and Protein S Deficiency

Protein C is a 62 kd glycoprotein with a half-life of 6 hours. Because it is vitamin K dependent, a deficiency will develop in the absence of vitamin K. Acquired protein C deficiency is seen in liver disease, malignancy, infection, the postoperative state, and disseminated intravascular coagulation. Protein C deficiency occurs in approximately 4% to 5% of patients younger than 40 to 45 years who present with unexplained venous thrombosis.

It is transmitted as an autosomal dominant trait, and the family history is usually positive for a clotting tendency. Protein C levels range from 70% to 164% of normal in patients without a clotting tendency; levels below 70% of normal are associated with a thrombotic tendency. The most appropriate tests for screening are functional assays; there are cases of dysfunctional protein C deficiency in which protein C antigen levels are normal but protein C activity is low, and these would not be detected by the usual immunoassays.

Protein S is a vitamin K-dependent protein that acts as a cofactor for activated protein C by enhancing protein C-induced inactivation of activated factor V. The incidence of protein S deficiency is similar to that of protein C deficiency. It is transmitted as a dominant trait, and the family history is often positive for a thrombotic tendency.

Hyperhomocysteinemia

Although hyperhomocysteinemia is more commonly associated with cardiac disease and arterial thrombosis, it may also be associated with an increased incidence of venous thromboembolism. This association is not as strong as those already discussed. Accordingly, anticoagulation of asymptomatic patients with elevated homocysteine levels is not currently recommended.

Dysfibrinogenemia

More than 100 qualitative abnormalities of fibrinogen (dysfibrinogenemias) have been reported. Dysfibrinogenemias are inherited in an autosomal dominant manner, with most patients being heterozygous. Most patients with dysfibrinogenemia have either no clinical symptoms or symptoms of a bleeding disorder; a minority (about 11%) have clinical features of a recurrent thromboembolic disorder. Congenital dysfibrinogenemias associated with thrombosis account for about 1% of cases of unexplained venous thrombosis occurring in young people. The most commonly observed functional defect in such dysfibrinogenemias is abnormal fibrin monomer polymerization combined with resistance to fibrinolysis. Decreased binding of plasminogen and increased resistance to lysis by plasmin have been noted.

In addition to a prolonged TT, patients who have dysfibrinogenemia associated with thromboembolism may have a prolonged INR. The diagnosis is confirmed if the reptilase time is also prolonged. Measured with clotting techniques, fibrinogen levels may be slightly or moderately low; measured immunologically, levels may be normal or even increased.

Dysfibrinolysis

Fibrinolysis can be impaired by inherited deficiencies of plasminogen, defective release of t-PA from the vascular endothelium, and high plasma levels of regulatory proteins (e.g., t-PA inhibitors). In addition, factor XII (contact factor) deficiency may induce failure of fibrinolysis activation.

Inherited plasminogen deficiency is probably only rarely responsible for unexplained DVT in young patients. It is transmitted as an autosomal dominant trait. In heterozygous persons with a thrombotic tendency, plasminogen activity is about one half normal (3.9 to 8.4 $\mu\text{mol/ml}$). The euglobulin clot lysis time is prolonged. Functional assays should be carried out, and there should be full transformation of plasminogen into plasmin activators.

The important role of t-PA inhibitors I and II in the regulation of fibrinolysis is well defined. In normal plasma, t-PA inhibitor I is the primary inhibitor for both t-PA and urokinase. Release of t-PA inhibitor I by platelets results in locally increased concentrations where platelets accumulate. The ensuing local inhibition of fibrinolysis may help stabilize the hemostatic plug. t-PA inhibitor II is present in and secreted by monocytes and macrophages.

Factor XII deficiency is a rare cause of impaired fibrinolysis. Initial contact activation of factor XII not only results in activation of the clotting cascade and of the inflammatory response but also leads to plasmin generation. This intrinsic activation of fibrinolysis requires factor XII, prekallikrein, and high-molecular-weight kininogen. Patients with factor XII deficiencies can be identified by a prolonged aPTT in the absence of clinical bleeding.

Operative Venous Thrombectomy

In patients with acute iliofemoral DVT, surgical therapy is generally reserved for patients who worsen with anticoagulation therapy and those with phlegmasia cerulea dolens and impending venous gangrene. If the patient has phlegmasia cerulea dolens, a fasciotomy of the calf compartments is first performed. In iliofemoral DVT, a longitudinal venotomy is made in the common femoral vein and a venous balloon embolectomy catheter is passed through the thrombus into the IVC and pulled back several times until no further thrombus can be extracted. The distal thrombus in the leg is removed by manual pressure beginning in the foot. This is accomplished by application of a tight rubber elastic wrap beginning at the foot and extending to the thigh. If the thrombus in the femoral vein is old and cannot be extracted, the

vein is ligated. For a thrombus that extends into the IVC, the IVC is exposed transperitoneally and the IVC is controlled below the renal veins. The IVC is opened and the thrombus is removed by gentle massage. An intraoperative completion venogram is obtained to determine if any residual thrombus or stenosis is present. If a residual iliac vein stenosis is present, intraoperative angioplasty and stenting can be performed. In most cases, an arteriovenous fistula is then created by anastomosing the great saphenous vein (GSV) end to side with the superficial femoral artery in an effort to maintain patency of the thrombectomized iliofemoral venous segment. Heparin is administered postoperatively for several days. Warfarin anticoagulation is maintained for at least 6 months after thrombectomy. Complications of iliofemoral thrombectomy include PE in up to 20% of patients and death in <1% of patients.

One study followed 77 limbs for a mean of 8.5 years after thrombectomy for acute iliofemoral DVT. In limbs with successful thrombectomies, valvular competence in the thrombectomized venous segment was 80% at 5 years and 56% at 10 years. More than 90% of patients had minimal or no symptoms of postthrombotic syndrome. There were 12 (16%) early thrombectomy failures. Patients were required to wear compression stockings for at least 1 year after thrombectomy.

Survival rates for surgical pulmonary embolectomy have improved over the past 20 years with the addition of cardiopulmonary bypass. Emergency pulmonary embolectomy for acute PE is rarely indicated. Patients with preterminal massive PE (Fig. 5) for whom thrombolysis has failed or who have contraindications to thrombolytics may be candidates for this procedure. Open pulmonary artery embolectomy is performed through a posterolateral thoracotomy with direct visualization of the pulmonary arteries. Mortality rates range between 20 and 40%.

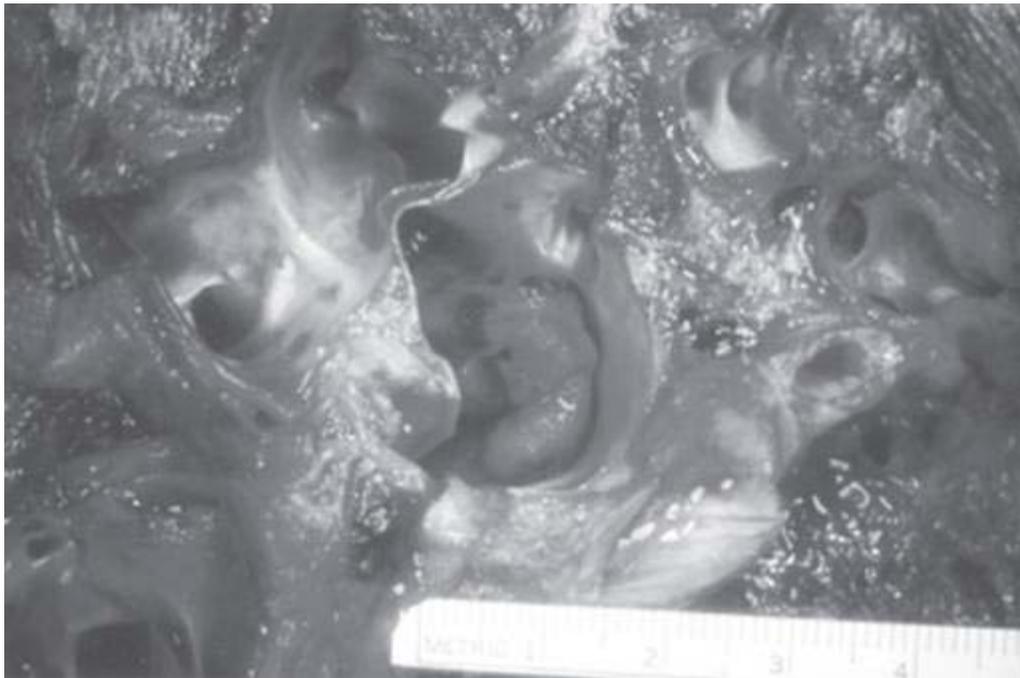

Fig. 5. Autopsy specimen showing a massive pulmonary embolism.

Percutaneous catheter-based techniques for removal of a PE involve mechanical thrombus fragmentation or embolectomy using suction devices. Mechanical clot fragmentation is followed by catheter-directed thrombolysis. Results of catheter-based fragmentation are based on small case series. In a study in which a fragmentation device was used in 10 patients with acute massive PE, fragmentation was successful in 7 patients with a mortality rate of 20%.⁶⁵ Transvenous catheter pulmonary suction embolectomy has also been performed for acute massive PE with a reported 76% successful extraction rate and a 30-day survival of 70%.⁶⁶

Prophylaxis

Patients who undergo major general surgical, gynecologic, urologic, and neurosurgical procedures without thromboprophylaxis have a significant incidence of perioperative DVT (15 to 40%). The incidence is even higher with major trauma (40 to 80%), hip and knee replacement surgery (40 to 60%), and spinal cord injury (60 to 80%). The goal of prophylaxis is to reduce the mortality and morbidity associated with VTE. The first manifestation of VTE may be a life-threatening PE (Fig. 6), and as indicated earlier, clinical evaluation to detect DVT before PE is unreliable.

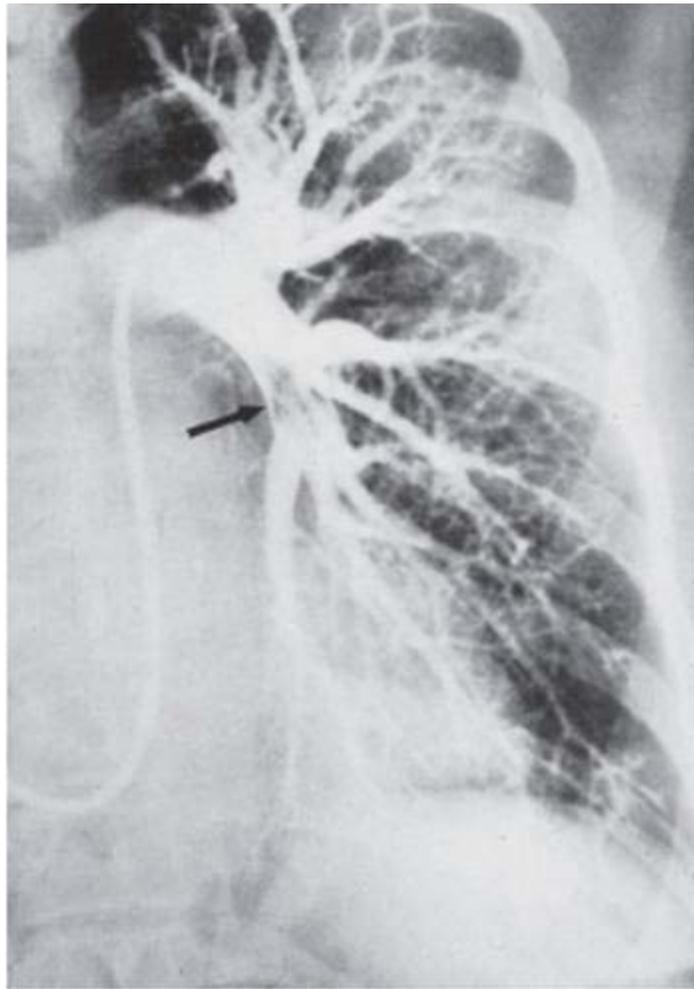

Fig. 6. Pulmonary angiogram showing a pulmonary embolism (*arrow*).

Effective methods of VTE prophylaxis involve the use of one or more pharmacologic or mechanical modalities. Currently available pharmacologic agents include low-dose UFH, LMWH, synthetic pentasaccharides, and vitamin K antagonists. Mechanical methods include intermittent pneumatic compression (IPC) and graduated compression stockings. Aspirin therapy alone is not adequate for DVT prophylaxis. These prophylaxis methods vary with regard to their efficacy, and the 2008 ACCP Clinical Practice Guidelines stratify their uses according to the patient's level of risk (Table 6).

Table 6. Thromboembolism Risk and Recommended Thromboprophylaxis in Surgical Patients

Level of Risk	Approximate DVT Risk without Thromboprophylaxis (%)	Suggested Thromboprophylaxis Options
Low risk	<10	No specific thromboprophylaxis
Minor surgery in mobile patients		Early and "aggressive" ambulation
Moderate risk	10-40	LMWH (at recommended doses), LDUH bid or tid, fondaparinux
Most general, open gynecologic, or urologic surgery		Mechanical thromboprophylaxis
Moderate VTE risk plus high bleeding risk		
High risk	40-80	LMWH (at recommended doses), fondaparinux, oral vitamin K antagonist (INR 2-3)
Hip or knee arthroplasty, hip fracture surgery		
Major trauma, spinal cord injury		Mechanical thromboprophylaxis
High VTE risk plus high bleeding risk		

Complications

Complications after venous thrombosis can vary from life threatening to chronically debilitating. Pulmonary embolism develops as venous thrombi break off from their location of origin and travel through the right heart and into the pulmonary artery, causing a ventilation perfusion defect and cardiac strain. PE occurs in approximately 10% of patients with acute deep venous thrombosis and can cause up to 10% of in hospital deaths.^{60,61} However, most patients (up to 75%) are asymptomatic. Traditionally, proximal venous thrombosis are thought to be at highest risk for causing pulmonary emboli; however, the single largest autopsy series ever performed to specifically to look for the source of fatal PE was performed by Havig in 1977, who found that one third of the fatal emboli arose directly from the calf veins.⁶

PHLEGMASIA ALBA AND CERULEA DOLENS

More than 600,000 cases of venous thromboembolism are estimated to occur each year in the United States. Pulmonary embolism (PE) complicates approximately 50% of cases of untreated proximal deep venous thrombosis (DVT) and contributes to 10-15% of all hospital deaths. Less frequent manifestations of venous thrombosis include phlegmasia alba dolens, phlegmasia cerulea dolens (PCD), and venous gangrene. These form a clinical spectrum of the same disorder. All 3 manifestations result from acute massive venous thrombosis and obstruction of the venous drainage of an extremity

History of the Procedure

In the 16th century, Fabricius Hildanus first described the clinical syndrome of what is currently called PCD. In 1938, Gregoire made an outstanding description of the condition and used the term PCD to differentiate ischemia-associated massive venous thrombosis from phlegmasia alba dolens, which describes fulminant venous thrombosis without ischemia.¹ The exact incidence of these disorders is not well reported.

In 1939, Leriche and Geissendorfer performed the first thrombectomy for cases of PCD.² Historically, surgical thrombectomy has been the procedure of choice for PCD refractory to medical therapy and in patients with established or impending gangrene.

Frequency

More than 600,000 cases of venous thromboembolism are estimated to occur annually in the United States. Phlegmasia alba dolens, PCD, and venous gangrene occur at any age but are more common during the fifth and sixth decades of life. Incidence is higher in females than in males.

Etiology

The main causative factor in phlegmasia is massive thrombosis and occlusion of major venous channels with significantly compromised venous outflow. Multiple triggering factors exist. Malignancy is the most common triggering factor and is present in approximately 20-40% of patients with PCD. Other associated risk factors include hypercoagulable syndrome, surgery, trauma, ulcerative colitis, gastroenteritis, heart failure, mitral valve stenosis, vena caval filter insertion, and May-Thurner syndrome (compression of the left iliac vein by the right iliac artery). Pregnancy has often been associated with phlegmasia alba dolens, especially during the third trimester when the uterus is large enough to compress the left common iliac vein against the pelvic rim (ie, milk leg syndrome). Finally, 10% of patients with phlegmasia have no apparent risk factors.

Pathophysiology

In phlegmasia alba dolens, the thrombosis involves only major deep venous channels of the extremity, therefore sparing collateral veins. The venous drainage is decreased but still

present; the lack of venous congestion differentiates this entity from PCD.

In PCD, the thrombosis extends to collateral veins, resulting in venous congestions with massive fluid sequestration and more significant edema. Without established gangrene, these phases are reversible if proper measures are taken.

Of PCD cases, 40-60% also have capillary involvement, which results in irreversible venous gangrene that involves the skin, subcutaneous tissue, or muscle. Under these conditions, the hydrostatic pressure in arterial and venous capillaries exceeds the oncotic pressure, causing fluid sequestration in the interstitium. Venous pressure may increase rapidly, as much as 16- to 17-fold within 6 hours. Fluid sequestration may reach 6-10 L in the affected extremity within days. Circulatory shock, which is present in about one third of patients, and arterial insufficiency may ensue.

The exact mechanism for the compromised arterial circulation is debatable but may involve shock, increased venous outflow resistance, and collapse of arterioles due to increased interstitial pressure. Vasospasm of the resistance vessels has also been hypothesized but has never been observed experimentally or radiographically.

Presentation

In the lower extremities, left-sided involvement is more common by a 3:1 or 4:1 ratio. Involvement of upper extremities occurs in less than 5% of patients with PCD. Manifestations may be gradual or fulminant. Of PCD cases, 50-60% are preceded by phlegmasia alba dolens, with symptoms of edema, pain, and blanching (alba) without cyanosis. The blanching, which previously was thought to be caused by arterial vasospasm, is caused by subcutaneous edema, without venous congestion.

Patients with PCD present with the clinical triad of edema, agonizing pain, and cyanosis. Massive fluid sequestration may lead to bleb and bullae formation. The pain is constant, usually starting at the femoral triangle and then progressing to the entire extremity. Cyanosis is the pathognomonic finding of PCD, progressing from distal to proximal areas.

When venous gangrene occurs, it has a similar distribution with the cyanosis. Arterial pulses may be present when the venous gangrene is superficial; however, gangrene that involves

the muscular compartment may result in increased compartment pressures and a pulse deficit. In addition, the pulses may be difficult to appreciate because of the significant edema. Various degrees of shock may be present because of significant fluid loss.

Indications

Historically, surgical thrombectomy has been the procedure of choice for phlegmasia cerulea dolens (PCD) refractory to medical therapy and for patients with established or impending gangrene. The standard treatment of phlegmasia and venous gangrene is evolving, but most clinicians attempt endovascular approaches to thrombolysis, if possible.

Relevant Anatomy

The main causative factor in phlegmasia is massive deep venous thrombosis (DVT) and occlusion of major venous channels with significantly compromised venous outflow. In phlegmasia alba dolens, the thrombosis involves only major deep venous channels of the extremity, therefore sparing collateral veins and preserving some venous outflow from the limb. In phlegmasia cerulea dolens (PCD), the thrombosis extends to collateral veins, with complete obstruction of venous outflow, resulting in massive venous congestion and fluid sequestration and more significant edema.

Contraindications

For phlegmasia alba dolens and mild nongangrenous forms of phlegmasia cerulea dolens (PCD), conservative medical treatment, rather than surgical thrombectomy, should be the initial course of therapy. Thrombolysis may be initiated if conservative management does not elicit a response and if the patient has no contraindication to lytic therapy.

Surgical thrombectomy cannot open the small venules that are affected in venous gangrene, and it does not prevent valvular incompetence or postphlebotic syndrome. For these reasons, thrombolysis seems to be an attractive alternative in the management of PCD and venous gangrene.

Imaging Studies

The diagnoses of phlegmasia alba dolens, phlegmasia cerulea dolens (PCD), and venous gangrene are established mainly via clinical criteria with the assistance of contrast venography and duplex ultrasonography.

Although venography is considered the criterion standard for diagnosis, technical difficulties may be encountered in as many as 20-25% of patients. Attempts to perform ascending venography when extensive deep system thrombosis is present may result in nonvisualization of the deep system and a nondiagnostic study result. In these cases, descending venography via the contralateral femoral vein or via the upper extremity veins may provide more information about the ilio caval system and proximal extent of the thrombus.

Recent improvements in ultrasonography have made this modality a more reliable and accurate way to assess for proximal deep venous thrombosis (DVT) with less morbidity. In addition, duplex imaging may be repeated as needed to monitor for thrombus propagation. Ultrasonography can also be performed at the bedside in patients who are critically ill or unstable. Ultrasonography is often used to guide the initial venipuncture for diagnostic venography and initiation of thrombolytic therapy.

Magnetic resonance venography (MRV) is an evolving modality of diagnostic imaging. Its principal advantage is its ability to easily reveal the proximal and distal extent of thrombus with a single study. Its principal disadvantage is the inability to image acutely ill patients with hemodynamic instability or motion artifacts due to pain.

Medical Therapy

The standard treatment of phlegmasia and venous gangrene is still evolving. The optimal therapeutic modality remains under debate. So far, the results of treatment have been moderately successful. For phlegmasia alba dolens and mild nongangrenous forms of phlegmasia cerulea dolens (PCD), conservative medical treatment, such as steep limb elevation, anticoagulation with intravenous administration of heparin, and fluid resuscitation, should be the initial course of therapy.

Initiate heparin administration with an intravenous bolus of 80-100 U/kg, followed by a continuous infusion of 15-18 U/kg/h. Frequently monitor the activated partial thromboplastin time (aPTT), with a goal range of 2-2.5 times the laboratory reference range. Frequently monitor platelet counts to allow the early detection of heparin-induced thrombocytopenia.

The purpose of rapid heparin anticoagulation is to decrease the risk of proximal clot propagation or thromboembolism. Heparin does not directly affect limb swelling. The best nonsurgical method to decrease edema is steep leg elevation.

Recent studies have demonstrated that low molecular weight heparins are safe and effective in the treatment of proximal deep venous thrombosis (DVT) and pulmonary embolism (PE); however, no good evidence supports the use of these newer agents in phlegmasia and venous gangrene.

If heparin-induced thrombocytopenia occurs, immediately discontinue the use of heparin and replace it with an alternative anticoagulant. Danaparoid and lepirudin are effective alternative agents; however, heparin-associated antibodies exhibit a 10-19% cross-reactivity with danaparoid. Thus, perform cross-reactivity testing before the initiation of danaparoid in patients with these antibodies. Lepirudin is a direct thrombin inhibitor that does not demonstrate any cross-reactivity. The recommended dosage of lepirudin in patients without renal failure is 0.4 mg/kg as an intravenous bolus followed by a continuous infusion of 0.15 mg/kg/h. Use aPTT to monitor therapy, with a goal range of 2-2.5 times the laboratory reference range.

Continue long-term anticoagulation with warfarin (or other coumarin derivatives) for at least 6 months. Life-long anticoagulation is recommended in patients with hypercoagulable states.

Patients should wear long-term prescription compression stockings with at least 30-40 mm Hg of graded pressure. Many physicians erroneously have the patient fitted for a prescription stocking while the limb is still severely edematous. Instead, the patient may use nonprescription stockings or an elastic bandage, in combination with elevation, to minimize edema prior to being fit for a prescription stocking.

Surgical Therapy

Surgical thrombectomy performed through a femoral venotomy allows instant decompression of the venous hypertension. An intraoperative Trendelenburg position may be

used to decrease the risk of PE. Transabdominal cavotomy and thrombectomy is an alternative approach that permits better control of the cava above the thrombus and, thus, provides protection against PE. Procedures that have been performed in an effort to decrease the rethrombosis rate include cross-pubic vein-to-vein reconstruction with polytetrafluoroethylene (PTFE) or the greater saphenous vein (GSV) or the creation of an arteriovenous fistula between the femoral artery and the GSV. These adjuvant procedures may be especially beneficial in cases that involve proximal iliofemoral vein constriction, damage, or external compression.

Concomitant administration of heparin and long-term anticoagulation are mandatory. Regardless, thrombectomy in patients with PCD is associated with a high rate of rethrombosis. Surgical thrombectomy cannot open the small venules that are affected in venous gangrene, and it does not prevent valvular incompetence or postphlebotic syndrome. The incidence of postphlebotic syndrome may be as high as 94% among survivors.

For the above reasons, thrombolysis seems to be an attractive alternative in the management of PCD and venous gangrene. In 1970, Paquet was the first to use thrombolysis for the treatment of PCD.⁴ Some authors propose catheter-directed thrombolysis directly into the vein with high doses of urokinase or tissue plasminogen activator (t-PA). Other authors support the method of intra-arterial low-dose thrombolysis via the common femoral artery, reasoning that the arterial route delivers the thrombolytic agent to the arterial capillaries and, subsequently, to the venules. The intra-arterial approach seems to be more effective in cases with venous gangrene. Systemic thrombolysis has also been used. Many authors have strongly recommended the insertion of a vena caval filter prior to initiation of thrombolytic therapy. Combine thrombolysis with heparin administration and long-term oral anticoagulation.

Fasciotomy alone or in conjunction with thrombectomy or thrombolysis reduces compartmental pressures; however, it significantly increases morbidity because of the prolonged wound healing and the risk of infection.

Finally, if all efforts fail and amputation is required, delay the procedure as long as possible. Take all precautions to reduce edema, allow venous channels to recanalize, and allow necrotic tissue to demarcate.

Preoperative Details

Patients who require emergent venous thrombectomy should have heparin continued throughout the perioperative period. Banked red blood cells should be available. The proximal extent of the thrombosis must be defined using a combination of venous ultrasonography for infrainguinal veins and retrograde venography of the iliac veins and inferior vena cava using a jugular or contralateral femoral approach. If the thrombosis extends into the iliac veins and vena cava, preparations should be made to control the cava via a right retroperitoneal incision. A high-quality fluoroscopy unit should be available to aid in catheter manipulation and completion venography.

Intraoperative Details

Operative exposure depends on the proximal and distal extent of the thrombus. The involved veins should be controlled proximally and distally prior to venotomy.

Iliac venous thrombectomy should be performed with large-bore thrombectomy balloon catheters (as large as 10F). Extension of the thrombus into the inferior vena cava may require proximal control of the cava. The anesthesiologist should apply positive airway pressure while the thrombus is being extracted from the ilio caval system. Digital subtraction venography should be performed to ascertain completeness of the thrombectomy.

Infrainguinal extraction of the thrombus is aided by the intraoperative placement of an Esmarch bandage from foot to thigh. Thrombectomy balloon catheters (3F and 4F) are passed through the femoral veins and, possibly, the posterior tibial veins as well.

Thrombolytic agents may be administered intraoperatively through the posterior tibial veins. t-PA is the most commonly used agent and may be administered intraoperatively.

After the thrombectomy is performed, an arteriovenous fistula should be constructed, connecting the proximal greater saphenous vein or one of its larger tributaries to the superficial femoral artery in an end-to-side fashion.

Completion venography should be performed to exclude the presence of residual thrombus or proximal venous stenosis. If one is present, balloon angioplasty with or without stent placement may be necessary.

When percutaneous endovascular therapy is performed as a single treatment modality, and many centers are now reporting this as a first-line therapy, the popliteal veins are usually

accessed with duplex ultrasonography as an aid. Prone positioning is rarely necessary. If extensive thrombus is present, access via the posterior tibial vein is usually successful. A 6-F sheath is usually adequate. An infusion wire is passed through the thrombus just to its proximal extent, often into the vena cava. Infusion is usually performed in the most proximal segment first, usually in the iliac veins.

A common protocol is to infuse tPA (1 mg/hr) through the infusion wire as well as through the sheath for 24 hours, then to change the sheath perfusion to lower dose heparin after 24 hours. The infusion is then performed in the superficial femoral and popliteal vein segments. Clinical improvement is often noted with clearing of the profunda venous segment. Performance of simultaneous percutaneous mechanical thrombectomy is controversial and may not give better results than postprocedure balloon dilation.

Postoperative Details

Intravenous heparin is administered throughout the postoperative period to prolong the aPTT (2-2.5 times the reference range for aPTT). This is continued until the patient is adequately anticoagulated with warfarin or one of the coumarin derivatives (international normalized ratio [INR] range of 2.0-3.0). The optimal duration of oral anticoagulation is not established.

A sequential compression device is also placed, or, at a minimum, an ace bandage is placed for control of edema. Once the edema is at its minimum, the patient may be fitted for a thigh-length compression stocking. Ambulation is encouraged, if the patient is able.

Complications

The incidence of postphlebotic syndrome may be as high as 94% among survivors. Pulmonary embolism is common, and prophylactic placement of an inferior vena cava filter is recommended in most cases. Thrombectomy in patients with phlegmasia cerulea dolens (PCD) is associated with a high rate of rethrombosis. Amputation and death are common.

Outcome and Prognosis

Despite all of the therapeutic modalities described above, phlegmasia cerulea dolens (PCD) and venous gangrene still remain life-threatening and limb-threatening conditions with overall mortality rates of 20-40%. Pulmonary embolism (PE) is responsible for 30% of the deaths reported from PCD. Overall, amputation rates of 12-50% have been reported among survivors. The postphlebitic sequelae are apparent in 60-94% of survivors. Strict adherence to the use of long-term compression stockings helps to control chronic edema.

Future and Controversies

Phlegmasia alba dolens, phlegmasia cerulea dolens (PCD), and venous gangrene still remain a challenge to the vascular surgeon. Treatment modalities continue to evolve. Endovascular management may offer hope of successful and more effective management, with less morbidity, than traditional surgery. The role of mechanical thrombectomy, compared with thrombolysis, is unclear. Small numbers of patients and lack of randomized trials preclude clear recommendations.

TOPIC № 13. PULMONARY EMBOLISM

Introduction

Background

Pulmonary embolism (PE) is as well recognized a thromboembolic disease, as are cerebral infarction and myocardial infarction in Western countries. However, the number of the patients with PE is still much lower in Japan than in the West. The Ministry of Health, Labor and Welfare in Japan reported in a patient survey that there were 1,220,000 patients with cerebral infarction, 82,000 with myocardial infarction, and only 4,000 with PE in 1999 . Vital statistics in the same year found 51,688 deaths from cerebral infarction, 48,806 from myocardial infarction, and only 1,738 from pulmonary embolism. In this chapter, we show the epidemiological results on PE in Japan, and consider the reasons for the difference in the incidence of PE between Japan and Western countries.

From the point of view of vital statistics, crude deaths from PE rapidly increased, and female deaths exceeded male deaths in the 1990s.

Age-specific mortality was higher in the elderly and, in recent years, lower in females than in males. The results of crude deaths reflect the fact that many more elderly people are female than male. The adjusted mortality in 1996 was 0.71 per 100,000 persons in males and 0.83 in females, which is comparable to the mortality of non-Blacks and non-Whites in the United States. The reduced mortality in the United States was achieved by widespread prevention of venous thromboembolism.

Pulmonary embolism (PE) is a relatively common cardiovascular emergency. By occluding the pulmonary arterial bed it may lead to acute life-threatening but potentially reversible right ventricular failure. PE is a difficult diagnosis that may be missed because of non-specific clinical presentation. However, early diagnosis is fundamental, since immediate treatment is highly effective. Depending on the clinical presentation, initial therapy is primarily aimed either at life-saving restoration of flow through occluded pulmonary arteries (PA) or at the prevention of potentially fatal early recurrences.

Both initial treatment and the long-term anticoagulation that is required for secondary prevention must be justified in each patient by the results of an appropriately validated diagnostic strategy.

Pulmonary embolism (PE) is a common and potentially lethal condition. Most patients who succumb to pulmonary embolism do so within the first few hours of the event. In patients who survive, recurrent embolism and death can be prevented with prompt diagnosis and therapy. Unfortunately, the diagnosis is often missed because patients with pulmonary embolism present with nonspecific signs and symptoms. If left untreated, approximately one third of patients who survive an initial pulmonary embolism die from a subsequent embolic episode.

The most important conceptual advance regarding pulmonary embolism over the last several decades has been the realization that pulmonary embolism is not a disease; rather, pulmonary embolism is a complication of venous thromboembolism, most commonly deep venous thrombosis (DVT). Virtually every physician who is involved in patient care (eg, internist, family physician, orthopedic surgeon, gynecologic surgeon, urologic surgeon, pulmonary subspecialist, cardiologist) encounters patients who are at risk for venous thromboembolism, and therefore at risk for pulmonary embolism.

Fig. 1. A large pulmonary artery thrombus in a hospitalized patient who died suddenly.

Fig. 2. Pulmonary embolism was identified as the cause of death in a patient who developed shortness of breath while hospitalized for hip joint surgery

Pathophysiology

The pathophysiology of pulmonary embolism encompasses several aspects, as described below.

Natural history of venous thrombosis

In the 19th century, Virchow identified a triad of factors that lead to venous thrombosis: venous stasis, injury to the intima, and enhanced coagulation properties of the blood. Thrombosis usually originates as a platelet nidus on valves in the veins of the lower extremities. Further growth occurs by accretion of platelets and fibrin and progression to red fibrin thrombus, which may either break off and embolize or result in total occlusion of the vein. The endogenous thrombolytic system leads to partial dissolution; then, the thrombus becomes organized and is incorporated into the venous wall.

Natural history of pulmonary embolism

Pulmonary emboli usually arise from the thrombi originating in the deep venous system of the lower extremities; however, rarely they may originate in the pelvic, renal, or upper extremity veins or the right heart chambers. After traveling to the lung, large thrombi can lodge at the bifurcation of the main pulmonary artery or the lobar branches and cause hemodynamic compromise. Smaller thrombi typically travel more distally, occluding smaller vessels in the lung periphery. These are more likely to produce pleuritic chest pain by initiating an inflammatory response adjacent to the parietal pleura. Most pulmonary emboli are multiple, and the lower lobes are involved more commonly than the upper lobes.

Respiratory consequences

Acute respiratory consequences of pulmonary embolism include increased alveolar dead space, pneumoconstriction, hypoxemia, and hyperventilation. Later, 2 additional consequences may occur: regional loss of surfactant and pulmonary infarction (see the image below). Arterial hypoxemia is a frequent but not universal finding in patients with acute embolism. The mechanisms of hypoxemia include ventilation-perfusion mismatch, intrapulmonary shunts, reduced cardiac output, and intracardiac shunt via a patent foramen ovale. Pulmonary infarction is an uncommon consequence because of the bronchial arterial collateral circulation.

Fig. 3. Lung infarction secondary to pulmonary embolism occurs rarely.

Hemodynamic consequences

Pulmonary embolism reduces the cross-sectional area of the pulmonary vascular bed, resulting in an increment in pulmonary vascular resistance, which, in turn, increases the right ventricular afterload. If the afterload is increased severely, right ventricular failure may ensue. In addition, the humoral and reflex mechanisms contribute to the pulmonary arterial constriction. Prior poor cardiopulmonary status of the patient is an important factor leading to hemodynamic collapse. Following the initiation of anticoagulant therapy, the resolution of emboli occurs rapidly during the first 2 weeks of therapy. Significant long-term nonresolution of emboli causing pulmonary hypertension or cardiopulmonary symptoms is uncommon.

Frequency

United States

The incidence of pulmonary embolism in the United States is estimated at 1 case per 1000 persons per year.¹ Studies from 2008 suggest that the increasing use of computed tomography (CT) for assessing patients with possible pulmonary embolism has led to an increase in the reported incidence of pulmonary embolism.^{2,3}

Pulmonary embolism is present in 60-80% of patients with DVT, even though more than half these patients are asymptomatic. Pulmonary embolism is the third most common cause of death in hospitalized patients, with at least 650,000 cases occurring annually. Autopsy studies have shown that approximately 60% of patients who died in the hospital had pulmonary embolism, and the diagnosis was missed in up to 70% of the cases. Prospective studies have demonstrated DVT in 10-13% of all medical patients placed on bed rest for 1 week, 29-33% of all patients in medical intensive care units, 20-26% of patients with pulmonary diseases who are given bed rest for 3 or more days, 27-33% of those admitted to a critical care unit after a myocardial infarction, and 48% of patients who are asymptomatic after a coronary artery bypass graft.

A population-based study covering the years 1966-1995 collated the cases of DVT or pulmonary embolism in women during pregnancy or postpartum. The relative risk was 4.29, and the overall incidence of venous thromboembolism (absolute risk) was 199.7 incidents per 100,000 woman-years. Among postpartum women, the annual incidence was 5 times higher than in pregnant women (511.2 vs 95.8 incidents per 100,000 women).

The incidence of DVT was 3 times higher than that of pulmonary embolism (151.8 vs 47.9 incidents per 100,000 women). Pulmonary embolism was relatively less common during pregnancy versus the postpartum period (10.6 vs 159.7 incidents per 100,000 women).⁴ A national review of severe obstetric complications from 1998-2005 found a significant increase in the rate of pulmonary embolism associated with the increasing rate of cesarean delivery.

International

The incidence of pulmonary embolism may differ substantially from country to country; observed variation is likely due to differences in the accuracy of diagnosis rather than in the actual incidence.

Mortality/Morbidity

From 1979-1998, the age-adjusted death rate for pulmonary embolism in the United States decreased from 191 deaths per million population to 94 deaths per million population.¹ Regional studies covering more recent years have found either a slight decrease or no change in mortality.^{2,3}

As a cause of sudden death, massive pulmonary embolism is second only to sudden cardiac death. Autopsy studies of patients who died unexpectedly in a hospital setting have shown approximately 80% of these patients died from massive pulmonary embolism.

Approximately 10% of patients who develop pulmonary embolism die within the first hour, and 30% die subsequently from recurrent embolism. Anticoagulant treatment decreases the mortality rate to less than 5%.

The diagnosis of pulmonary embolism is missed in approximately 400,000 patients in the United States per year; approximately 100,000 deaths could be prevented with proper diagnosis and treatment.

Race

The incidence of pulmonary embolism appears to be significantly higher in blacks than in whites.⁶ Mortality rates from pulmonary embolism for blacks have been 50% higher than those for whites, and those for whites have been 50% higher than those for people of other races (eg, Asians, Native Americans).¹

Sex

The risk of pulmonary embolism is increased in pregnancy and during the postpartum period.

Data are conflicting regarding male sex as a risk factor for pulmonary embolism; however, an analysis of national mortality data found that death rates from pulmonary embolism were 20-30% higher among men than among women.¹

Age

In hospitalized elderly patients, pulmonary embolism is commonly missed and often is the cause of death.

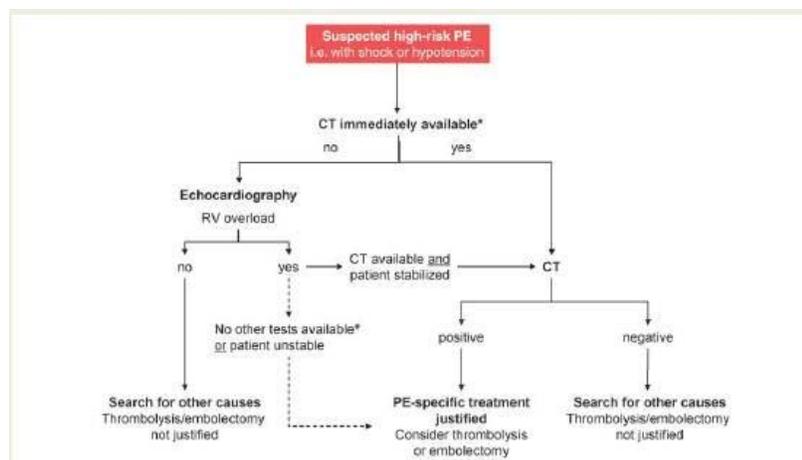

Clinical

Predisposing factors for venous thromboembolism

Predisposing factor	Patient-related	Setting-related
Strong predisposing factors (odds ratio >10)		
Fracture (hip or leg)		✓
Hip or knee replacement		✓
Major general surgery		✓
Major trauma		✓
Spinal cord injury		✓
Moderate predisposing factors (odds ratio 2–9)		
Arthroscopic knee surgery		✓
Central venous lines		✓
Chemotherapy		✓
Chronic heart or respiratory failure	✓	
Hormone replacement therapy	✓	
Malignancy	✓	
Oral contraceptive therapy	✓	
Paralytic stroke	✓	
Pregnancy/postpartum		✓
Previous VTE	✓	
Thrombophilia	✓	
Weak predisposing factors (odds ratio <2)		
Bed rest >3 days		✓
Immobility due to sitting (e.g. prolonged car or air travel)		✓
Increasing age	✓	
Laparoscopic surgery (e.g. cholecystectomy)		✓
Obesity	✓	
Pregnancy/antepartum	✓	
Varicose veins	✓

		PE unlikely	0–4
		PE likely	>4

Diagnostic algorithm for patients with suspected high-risk PE

History

The presentation of pulmonary embolism (PE) may vary from sudden catastrophic hemodynamic collapse to gradually progressive dyspnea. The diagnosis of pulmonary embolism should be sought actively in patients with respiratory symptoms unexplained by an alternate diagnosis. The symptoms of pulmonary embolism are nonspecific; therefore, a high index of suspicion is required, particularly when a patient has risk factors for the condition/

The presentation of patients with pulmonary embolism can be categorized into 4 classes based on the acuity and severity of pulmonary arterial occlusion. These categories are (1) massive pulmonary embolism, (2) acute pulmonary infarction, (3) acute embolism without infarction, and (4) multiple pulmonary emboli.

Massive pulmonary embolism

Large emboli compromise sufficient pulmonary circulation to produce circulatory collapse and shock.

The patient has hypotension; appears weak, pale, sweaty, and oliguric; and develops impaired mentation.

Acute pulmonary infarction

Approximately 10% of patients have peripheral occlusion of a pulmonary artery causing parenchymal infarction.

These patients present with acute onset of pleuritic chest pain, breathlessness, and hemoptysis.

Although the chest pain may be clinically indistinguishable from ischemic myocardial pain, normal electrocardiogram findings and no response to nitroglycerin rules it out.

Acute embolism without infarction: Patients have nonspecific symptoms of unexplained dyspnea and/or substernal discomfort.

Multiple pulmonary emboli

This group comprises 2 subsets of patients.

The first subset has repeated documented episodes of pulmonary emboli over years, eventually presenting with signs and symptoms of pulmonary hypertension and cor pulmonale.

The second subset has no previously documented pulmonary emboli but has widespread obstruction of the pulmonary circulation with clot. They present with gradually progressive dyspnea, intermittent exertional chest pain, and, eventually, features of pulmonary hypertension and cor pulmonale.

Most patients with pulmonary embolism have no obvious symptoms at presentation. In contrast, patients with symptomatic DVT commonly have pulmonary embolism confirmed on diagnostic studies in the absence of pulmonary symptoms.

The most common symptoms of pulmonary embolism in the Prospective Investigation of Pulmonary Embolism Diagnosis (PIOPED) study were dyspnea (73%), pleuritic chest pain (66%), cough (37%), and hemoptysis (13%).⁷ However, patients with pulmonary embolism may present with atypical symptoms. In such cases, strong suspicion of pulmonary embolism based on the presence of risk factors can lead to consideration of pulmonary embolism in the differential diagnosis. These symptoms include the following:

Seizures

Syncope

Abdominal pain

Fever

Productive cough

Wheezing

Decreasing level of consciousness

New onset of atrial fibrillation

Flank pain

Delirium (in elderly patients)

Pleuritic chest pain without other symptoms or risk factors may be a presentation of pulmonary embolism.

Physical

Physical examination findings are quite variable in pulmonary embolism and, for convenience, may be grouped into 4 categories as follows:

Massive pulmonary embolism

These patients are in shock. They have systemic hypotension, poor perfusion of the extremities, tachycardia, and tachypnea.

Additionally, signs of pulmonary hypertension such as palpable impulse over the second left intercostal space, loud P2, right ventricular S3 gallop, and a systolic murmur louder on inspiration at left sternal border (tricuspid regurgitation) may be present.

Acute pulmonary infarction

These patients have decreased excursion of the involved hemithorax, palpable or audible pleural friction rub, and even localized tenderness.

Signs of pleural effusion, such as dullness to percussion and diminished breath sounds, may be present.

Acute embolism without infarction

These patients have nonspecific physical signs that may easily be secondary to another disease process.

Tachypnea and tachycardia frequently are detected, pleuritic pain sometimes may be present, crackles may be heard in the area of embolization, and local wheeze may be heard rarely.

Multiple pulmonary emboli or thrombi

Patients belonging to both the subsets in this category have physical signs of pulmonary hypertension and cor pulmonale.

Patients may have elevated jugular venous pressure, right ventricular heave, palpable impulse in the left second intercostal space, right ventricular S3 gallop, systolic murmur over the left sternal border that is louder during inspiration, hepatomegaly, ascites, and dependent pitting edema.

These findings are not specific for pulmonary embolism and require a high index of suspicion for pursuing appropriate diagnostic studies.

The most common physical signs in the PIOPED study were as follows:

Tachypnea (70%)

Rales (51%)

Tachycardia (30%)

Fourth heart sound (24%)

Accentuated pulmonic component of the second heart sound (23%)

Fever of less than 39°C may be present in 14% of patients; however, temperature higher than 39.5°C is not from pulmonary embolism. Finally, chest wall tenderness upon palpation, without a history of trauma, may be the sole physical finding in rare cases.

Causes

The causes for pulmonary embolism are multifactorial and are not readily apparent in many cases. The following causes have been described in the literature:

Venous stasis

Venous stasis leads to accumulation of platelets and thrombin in veins.

Increased viscosity may occur due to polycythemia and dehydration, immobility, raised venous pressure in cardiac failure, or compression of a vein by a tumor.

Hypercoagulable states

The complex and delicate balance between coagulation and anticoagulation is altered by many diseases, by obesity, after surgery, or by trauma.

Concomitant hypercoagulability may be present in disease states where prolonged venous stasis or injury to veins occurs.

Hypercoagulable states may be acquired or congenital. Factor V Leiden mutation causing resistance to activated protein C is the most common risk factor. Factor V Leiden mutation is present in up to 5% of the normal population and is the most common cause of familial thromboembolism.

Primary or acquired deficiencies in protein C, protein S, and antithrombin III are other risk factors. The deficiency of these natural anticoagulants is responsible for 10% of venous thrombosis in younger people

Immobilization

Immobilization leads to local venous stasis by accumulation of clotting factors and fibrin, resulting in thrombus formation.

The risk of pulmonary embolism increases with prolonged bed rest or immobilization of a limb in a cast.

Paralysis increases the risk.

Surgery and trauma

Both surgical and accidental trauma predispose patients to venous thromboembolism by activating clotting factors and causing immobility.

Fractures of the femur and tibia are associated with the highest risk, followed by pelvic, spinal, and other fractures.

Severe burns carry a high risk of DVT or pulmonary embolism.

A prospective study by Geerts and colleagues in 1994 indicated that major trauma was associated with a 58% incidence of DVT in the lower extremities and an 18% incidence in proximal veins.¹⁰

Pulmonary embolism may account for 15% of all postoperative deaths. Leg amputations and hip, pelvic, and spinal surgery are associated with the highest risk.

Pregnancy

The incidence of thromboembolic disease in pregnancy has been reported to range from 1 case in 200 deliveries to 1 case in 1400 deliveries.

Fatal events may occur rarely, 1-2 cases per 100,000 pregnancies.

The mechanism of DVT is venous stasis, decreasing fibrinolytic activity, and increased procoagulant factors.

Oral contraceptives and estrogen replacement

Estrogen-containing birth control pills have increased the occurrence of venous thromboembolism in healthy women.

The risk is proportional to the estrogen content and is increased in postmenopausal women on hormonal replacement therapy.

The relative risk is 3-fold, but the absolute risk is 20-30 cases per 100,000 persons per year.

Malignancy

Malignancy has been identified in 17% of patients with venous thromboembolism.

The neoplasms most commonly associated with pulmonary embolism, in descending order of frequency, are pancreatic carcinoma; bronchogenic carcinoma; and carcinomas of the genitourinary tract, colon, stomach, and breast.

In the PIOPED II study, immobilization (usually because of surgery) was the risk factor most commonly assessed in patients with pulmonary embolism; 94% of all patients with pulmonary embolism had 1 or more of the following risk factors¹¹ :

Immobilization

Travel of 4 hr or more in the past month

Surgery within the last 3 months

Malignancy, especially lung cancer

Current or past history of thrombophlebitis

Trauma to the lower extremities and pelvis during the past 3 months

Smoking

Central venous instrumentation within the past 3 months

Stroke, paresis, or paralysis

Prior pulmonary embolism

Heart failure

Chronic obstructive pulmonary disease

Other recognized risk factors include the following:

Obesity

Varicose veins

Inflammatory bowel disease

Laboratory Studies

Clinical signs and symptoms for pulmonary embolism (PE) are nonspecific; therefore, patients suspected of having pulmonary embolism—because of unexplained dyspnea, tachypnea, or chest pain or the presence of risk factors for pulmonary embolism—must undergo diagnostic tests until the diagnosis is ascertained or eliminated or an alternative diagnosis is confirmed. Further, routine laboratory findings are nonspecific and are not helpful in pulmonary embolism, although they may suggest another diagnosis.

Evidence-based literature supports the practice of determining the clinical probability of pulmonary embolism before

proceeding with testing. A clinical practice guideline from the American Academy of Family Physicians (AAFP) and the American College of Physicians (ACP) recommends that validated clinical prediction rules be used to estimate pretest probability of pulmonary embolism and to interpret test results. The guideline, Current diagnosis of venous thromboembolism in primary care, advocates use of the Wells prediction rule for this purpose, but notes that the Wells rule performs better in younger patients without comorbidities or a history of venous thromboembolism.

Table 1. Wells Prediction Rule for Diagnosing Pulmonary Embolism: Clinical Evaluation Table for Predicting Pretest Probability of Pulmonary Embolism

Clinical Characteristic	Score
Previous pulmonary embolism or deep vein thrombosis	+1.5
Heart rate greater than 100 beats per minute	+1.5
Recent surgery or immobilization (within the last 30 d)	+1.5
Clinical signs of deep vein thrombosis	+3
Alternative diagnosis less likely than pulmonary embolism	+3
Hemoptysis	+1
Cancer (treated within the last 6 mo)	+1

Note: Clinical probability of pulmonary embolism: low 0–1; intermediate 2–6; high 7 or more
 Reprinted from *Am J Med*, Vol 113, Chagnon I, Bounameaux H, Aujesky D, et al, Comparison of two clinical prediction rules and implicit assessment among patients with suspected pulmonary embolism, pp 269-75, Copyright 2002.

Another validated clinical prediction rule for use in the diagnosis of pulmonary embolism is the revised Geneva score. The performance of the revised Geneva score appears equivalent to that of the Wells score.

Table 2 The Revised Geneva Score

Risk Factors	Points
Age older than 65 y	1
Previous DVT or PE	3
Surgery (under general anesthesia) or fracture (of the lower limbs) within 1 mo	2
Active malignant condition (solid or hematologic, currently active or considered cured less than 1 y)	2
Symptoms	
Unilateral lower limb pain	3
Hemoptysis	2
Clinical Signs	
Heart rate 75–94 beats/min	3
Heart rate ≥ 95 beats/min	5
Pain on lower limb deep venous palpation and unilateral edema	4
Clinical Probability	
Low	0–3 total
Intermediate	4–10 total
High	≥ 11 total

*Adapted from Prediction of pulmonary embolism in the emergency department: the revised Geneva score. Le Gal G, Righini M, Roy PM, Sanchez O, Aujesky D, Bounameaux H, Perrier A. *Ann Intern Med.* 2006 Feb 7;144(3):165-71.

Simplified versions of the Wells score and the revised Geneva score have been developed. Initial studies support the validity of these scores, which assign 1 point to each of the criteria.

D-dimer testing

When clinical prediction rule results indicate that the patient has a low or moderate pretest probability of pulmonary embolism, D-dimer testing is the usual next step. Negative results on a high-sensitivity D-dimer test in a patient with a low pretest probability of pulmonary embolism indicate a low likelihood of venous thromboembolism and reliably exclude pulmonary embolism. A large prospective randomized trial found that in patients with a low probability of pulmonary embolism who had negative D-dimer results, forgoing additional diagnostic testing was not associated with an increased frequency of symptomatic venous thromboembolism during the subsequent 6 months.²⁰

D-dimer, a degradation product produced by plasmin-mediated proteases of cross-linked fibrin, is measured by a variety of assay types, including quantitative, semiquantitative, and qualitative rapid enzyme-linked immunosorbent assays (ELISAs); quantitative and semiquantitative latex; and whole-blood assays. A systematic review of prospective studies of high methodologic quality concluded that the ELISAs—especially the quantitative rapid ELISA—dominate the comparative ranking among the D-dimer assays for sensitivity and negative likelihood ratio. The quantitative rapid ELISA has a sensitivity of 0.95 and negative likelihood ratio of 0.13; the latter is similar to that for a normal to near-normal lung scan in patients with suspected pulmonary embolism.

D-dimer testing is most reliable for excluding pulmonary embolism in younger patients who have no associated comorbidity or history of venous thromboembolism and whose symptoms are of short duration.¹⁴ D-dimer testing is of questionable value in patients who are older than 80 years, are hospitalized, or have cancer and in pregnant women, because nonspecific elevation of D-dimer concentrations is common in such patients. D-dimer test should not be used when the clinical probability of pulmonary embolism is high, because the test has low negative predictive value in such cases.

Troponins

Serum troponin levels can be elevated in up to 50% of patients with a moderate-to-large pulmonary embolism, presumptively due to acute right ventricular myocardial stretch.

Although not currently recommended as part of the diagnostic workup, studies have shown that elevated troponin levels in the setting of pulmonary embolism correlate with increased mortality. Currently, further studies need to be performed to identify subsets of patients with pulmonary embolism who might benefit from this testing.

A meta-analysis by Jimenez et al suggests that in acute symptomatic pulmonary embolism (PE), elevated troponin levels do not distinguish between patients who are at high risk for death and those who are at low risk. Pooled results from studies including 1366 normotensive patients with acute symptomatic PE showed that elevated troponin levels were associated with a 4.26-fold increased odds of overall mortality (95% confidence interval [CI], 2.13-8.50; heterogeneity $\chi^2 = 12.64$; degrees of freedom = 8; $P = .125$). Summary receiver operating characteristic curve analysis showed a relationship between the sensitivity and specificity of troponin levels to predict overall mortality (Spearman rank correlation coefficient = 0.68; $P = .046$). Pooled likelihood ratios (LRs) were not extreme (negative LR, 0.59 [95% CI, 0.39-0.88]; positive LR, 2.26 [95% CI, 1.66-3.07]).

Brain natriuretic peptide

Although neither sensitive nor specific, patients with pulmonary embolism tend to have higher levels of brain natriuretic peptide (BNP). In one case-control study of 2213 hemodynamically stable patients with suspected acute pulmonary embolism, BNP testing had a sensitivity and specificity of only 60% and 62%, respectively.

Elevated levels of BNP or its precursor, N-terminal pro-brain natriuretic peptide (NT-proBNP), do correlate with an increased risk of subsequent complications and mortality in patients with acute pulmonary embolism. One meta-analysis revealed that patients with a BNP level greater than 100 pg/mL or an NT-proBNP level greater than 600 ng/L had an all-cause in-hospital mortality rate 6- and 16-fold higher than those below these cutoffs, respectively. In a second smaller observational study, serum BNP levels greater than 90 pg/mL were associated with a higher rate of complications, such as the need for cardiopulmonary resuscitation, need for mechanical ventilation, need for vasopressor therapy, and death.²⁸

BNP testing is not currently recommended as part of the standard evaluation of acute pulmonary embolism, and future studies may aid in defining its role in this setting.

Arterial blood gases

Arterial blood gas determinations characteristically reveal hypoxemia, hypocapnia, and respiratory alkalosis; however, the predictive value of hypoxemia is quite low.

Both the PaO₂ and the calculation of alveolar-arterial oxygen gradient contribute to the diagnosis in a general population thought to have pulmonary embolism.

Nonetheless, in high-risk settings such as patients in postoperative states in whom other respiratory conditions can be ruled out, a low PaO₂ in conjunction with dyspnea may have a strong positive predictive value.

Imaging Studies

Chest radiography

The American College of Radiology (ACR) recommends chest radiography as the most appropriate study for ruling out other causes of chest pain in patients with suspected pulmonary embolism.

Initially, the chest radiography findings are normal in most cases of pulmonary embolism. However, in later stages,

radiographic signs may include a Westermark sign (dilatation of pulmonary vessels and a sharp cutoff), atelectasis, a small pleural effusion, and an elevated diaphragm.

Although chest radiography findings may indicate an alternate diagnosis, this study alone is not sufficient to confirm the diagnosis of pulmonary embolism.

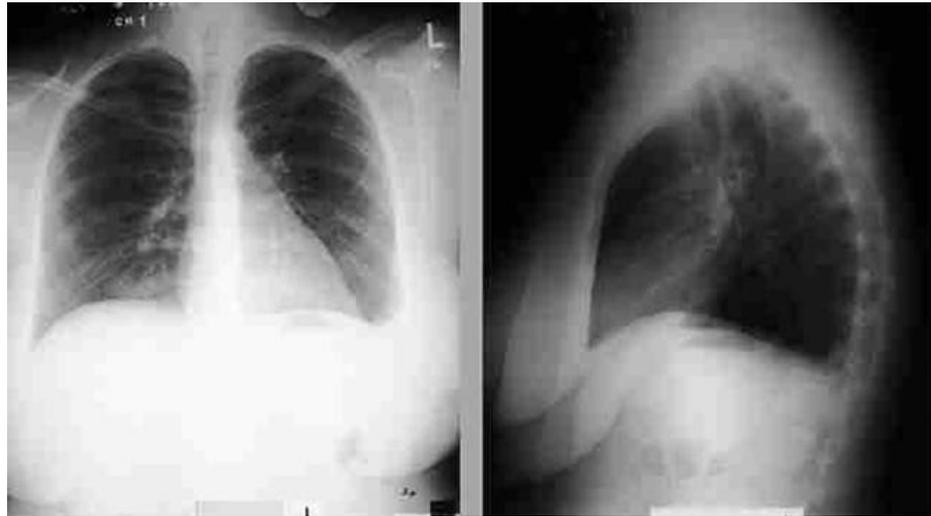

Fig. 4. Posteroanterior and lateral chest radiograph findings are normal, which is the usual finding in patients with pulmonary embolism

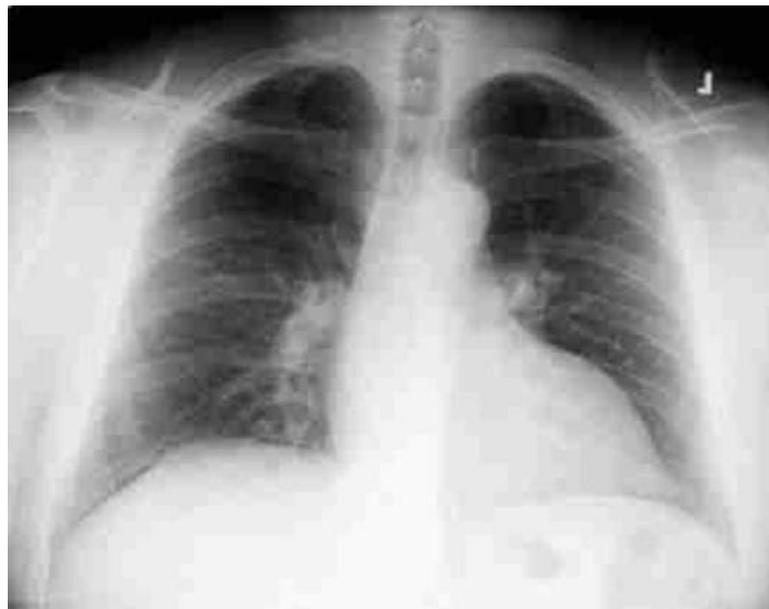

Fig. 5. A chest radiograph with normal findings in a 64-year-old woman who presented with worsening breathlessness.

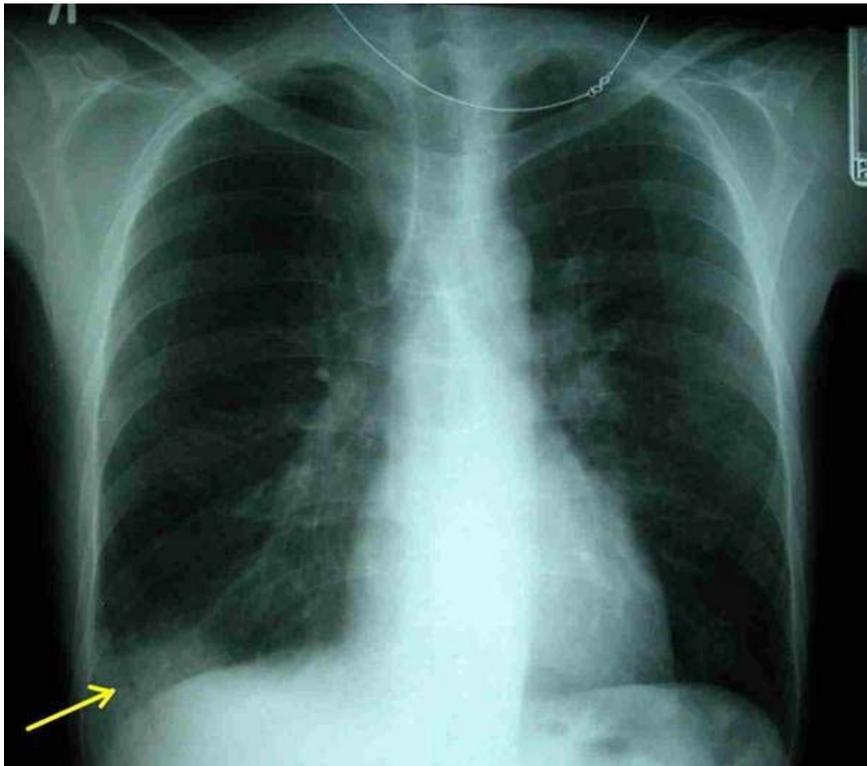

Fig.6. A posteroanterior chest radiograph showing a peripheral wedge-shaped infiltrate caused by pulmonary infarction secondary to pulmonary embolism. Hampton hump is a rare and nonspecific finding

Computed tomography

CT angiography (CTA) is the initial imaging modality of choice for stable patients with suspected pulmonary embolism. The ACR considers chest CTA the current standard of care for the detection of pulmonary embolism.²⁹

In patients with a negative CTA, the likelihood for subsequent thromboembolic events is extremely small.

The Christopher study, a prospective trial, used CT as part of a management algorithm for 3306 outpatients with suspected acute pulmonary embolism. Patients in whom the Wells rule indicated that pulmonary embolism was unlikely underwent D-dimer testing; if the result was normal, pulmonary embolism was considered excluded. All other patients underwent multidetector CT arteriography, and pulmonary embolism was considered present or excluded based on the results. Among patients with negative scan results who did not receive anticoagulation therapy, the 3-month incidence of venous thromboembolism was 1.3%; death, possibly from pulmonary embolism, occurred in 0.5%.³⁰

Similarly, a meta-analysis published in 2004 reviewed 23 studies reporting on 4657 patients with negative pulmonary CTA results for pulmonary embolism who did not receive anticoagulation. The rate of venous thromboembolism was 1.4% and the rate of fatal pulmonary embolism was 0.51% at 3 months. These results are similar to negative results on conventional pulmonary angiography. These investigators concluded that withholding anticoagulation after negative pulmonary CTA results appears to be safe.³¹

Spiral CT can visualize main, lobar, and segmental pulmonary emboli with a reported sensitivity of greater than 90%. Spiral CT scanning can help detect emboli as small as 2 mm that are affecting up to the seventh border division of the pulmonary artery. A further benefit of spiral CT scanning is that the results may suggest an alternative diagnosis in up to 57% of patients. A significant limitation of spiral CT scanning is that small subsegmental emboli may not be detected.

The technique is as follows:

Spiral CT examination is performed immediately after infusion of 150-200 mL of 30% contrast material.

Scanning is performed from the level of the aortic arch to approximately 2 cm below the level of the inferior pulmonary vein while the patient is holding his or her breath at full inspiration.

If the patient is not able to hold his or her breath for 20-30 seconds, scanning may be performed during gentle breathing.

Sensitivity and specificity of spiral CT scanning for pulmonary embolism are as follows:

The reported sensitivity is 53-100%.

The reported specificity is 78-96%.

The negative predictive value is 81-100%, and the positive predictive value is 60-100% for detecting emboli in segmental or larger arteries.

Positive findings on CT imaging include a central intravascular filling defect within the vessel lumen, eccentric tracking of contrast material around a filling defect, and complete vascular occlusion. Smooth filling defects making an obtuse angle with a vessel wall may represent chronic thrombi or recent recanalization. In the lung parenchyma, signs of pulmonary embolism include oligemia, pulmonary hemorrhage (ground-glass attenuation), and pulmonary infarction (peripheral wedge-shaped pleural-based opacification).

Pitfalls include the following:

Technically inadequate scans may result from patients' dyspnea and/or obliquely or horizontally oriented vessels within the right middle lobe and left lingula.

False filling defects may result from breathing artifact cardiac motion or unilateral extensive air space consolidation as a result of the significant decrease in blood flow through pulmonary arteries in these areas.

Combined spiral CT scanning for detection of pulmonary embolism and deep venous thrombosis (DVT)

A combined CT scan for PE/DVT enhances the utility of spiral CT scanning by further identifying emboli in the deep venous system of the lower extremities or the pelvic veins.

Good venous enhancement of the lower extremity veins occurs 2 minutes following lung CT scanning as 5-mm scans are performed at 5-cm intervals from the upper calves to the diaphragm.

Alternatively, 1-cm images are performed from the iliac bones to the tibial plateau. The additional radiation dose needs to be considered in the formulation of this protocol. With this technique, up to 4% of patients with negative results on CT scanning examination for pulmonary embolism have been identified to have DVT

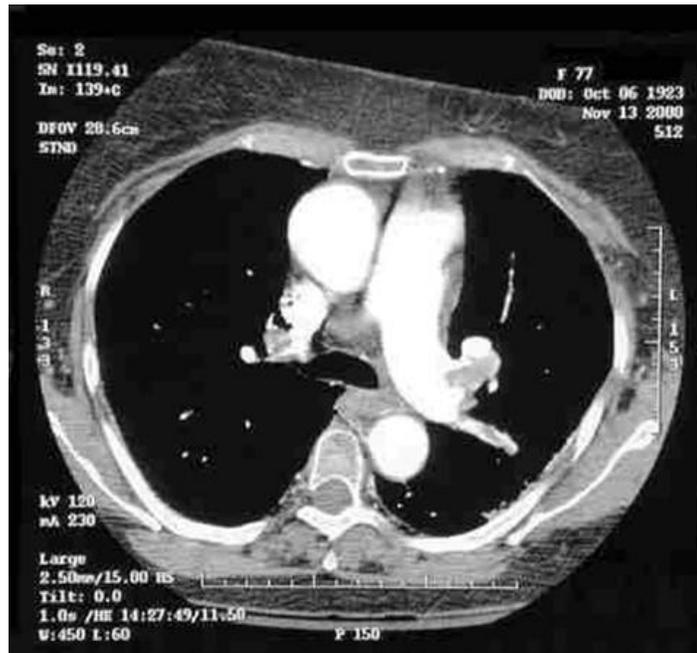

Fig. 7. A spiral CT scan shows thrombus in bilateral main pulmonary arteries.

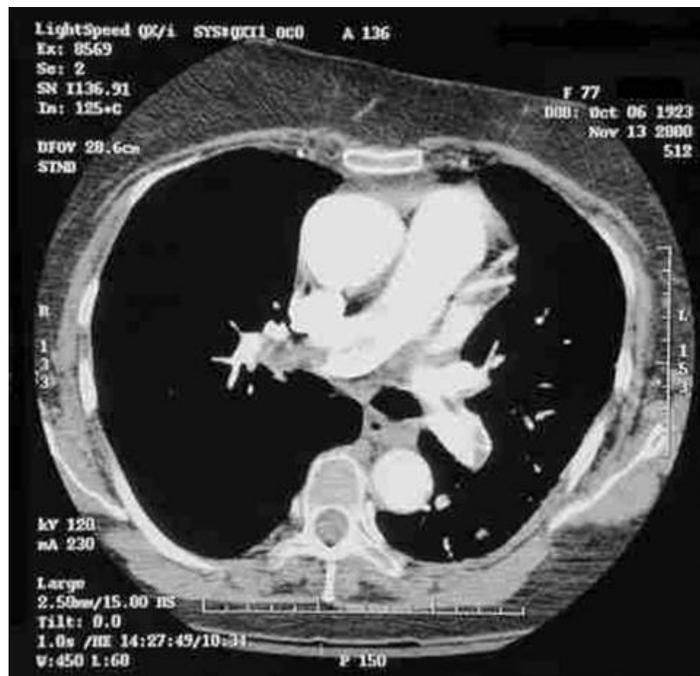

Fig. 8. A spiral CT scan shows thrombus in bilateral main pulmonary arteries

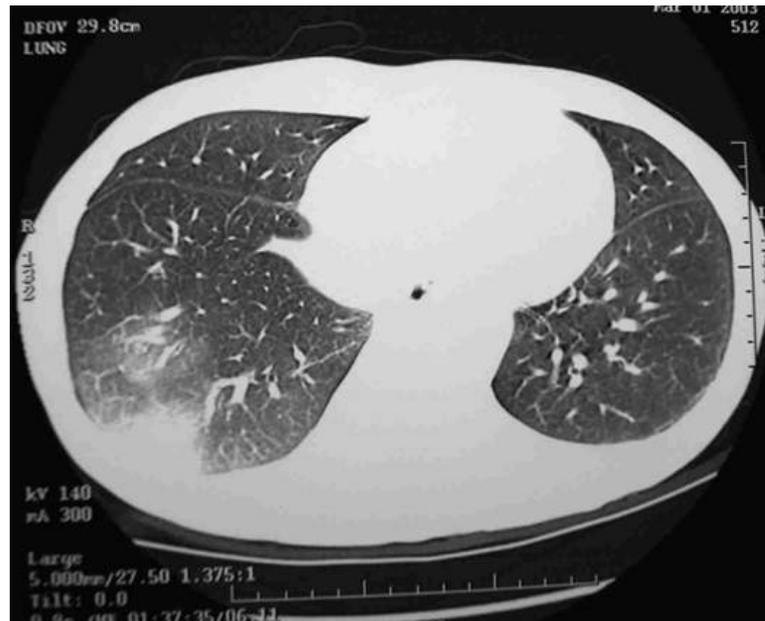

Fig. 9. CT scan

Ventilation-perfusion (V/Q) scanning of the lungs: This is an important diagnostic modality for establishing the diagnosis of pulmonary embolism. However, V/Q scanning should be used only when CT scanning is not available or if the patient has a contraindication to CT scanning or intravenous contrast material.

New criteria for V/Q scanning diagnosis of pulmonary embolism, from the Prospective Investigation of Pulmonary Embolism Diagnosis (PIOPED) II trial:

High probability criteria are as follows:

Two large (more than 75% of a segment) segmental perfusion defects without corresponding ventilation or chest radiographic abnormalities

One large segmental perfusion defect and 2 moderate (25-75% of a segment) segmental perfusion defects without corresponding ventilation or radiographic abnormalities

Four moderate segmental perfusion defects without corresponding ventilation or chest radiographic abnormalities

Intermediate probability criteria are as follows:

One moderate to fewer than 2 large segmental perfusion defects without corresponding ventilation or chest radiographic abnormalities

Corresponding V/Q defects and radiographic parenchymal opacity in lower lung zone

Single moderate matched V/Q defects with normal chest radiographic findings

Corresponding V/Q and chest radiography small pleural effusion

Difficult to categorize as normal, low, or high probability

Low probability criteria are as follows:

Multiple matched V/Q defects, regardless of size, with normal chest radiographic findings

Corresponding V/Q defects and radiographic parenchymal opacity in upper or middle lung zone

Corresponding V/Q defects and large pleural effusion

Any perfusion defects with substantially larger radiographic abnormality

Defects surrounded by normally perfused lung (stripe sign)

More than 3 small (less than 25% of a segment) segmental perfusion defects with normal chest radiographic findings

Nonsegmental perfusion defects (cardiomegaly, aortic impression, enlarged hila)

Very low criterion is 3 small (less than 25% of a segment) segmental perfusion defects with normal chest radiograph findings.

Normal finding is no perfusion defects and perfusion outlines the shape of the lung seen on a chest radiograph.

In the PIOPED II study, very low-probability V/Q scans in patients whose Wells score indicated low pretest probability of pulmonary embolism reliably excluded pulmonary embolism.

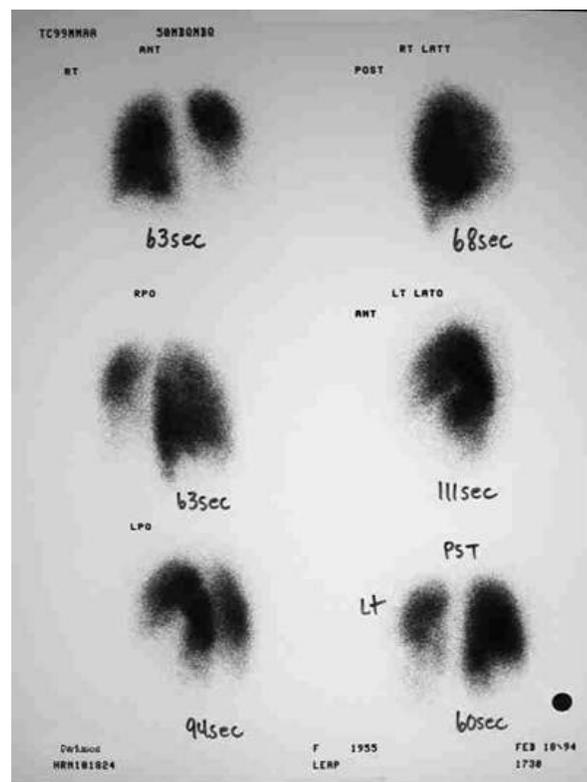

Fig. 10. High-probability perfusion lung scan shows segmental perfusion defects in the right upper lobe and subsegmental perfusion defects in right lower lobe, left upper lobe, and left lower lobe

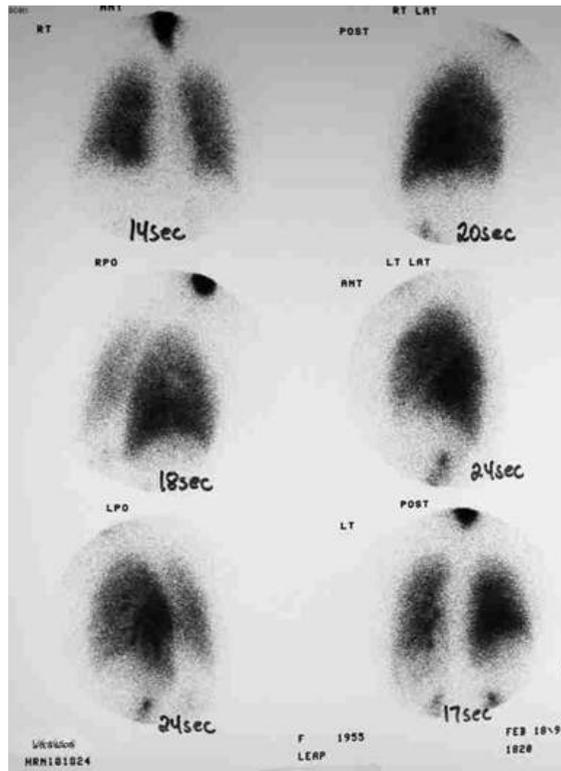

Fig. 11. A normal ventilation scan will make the above-noted defects in Image 5 a mismatch and, hence, a high-probability ventilation-perfusion scan

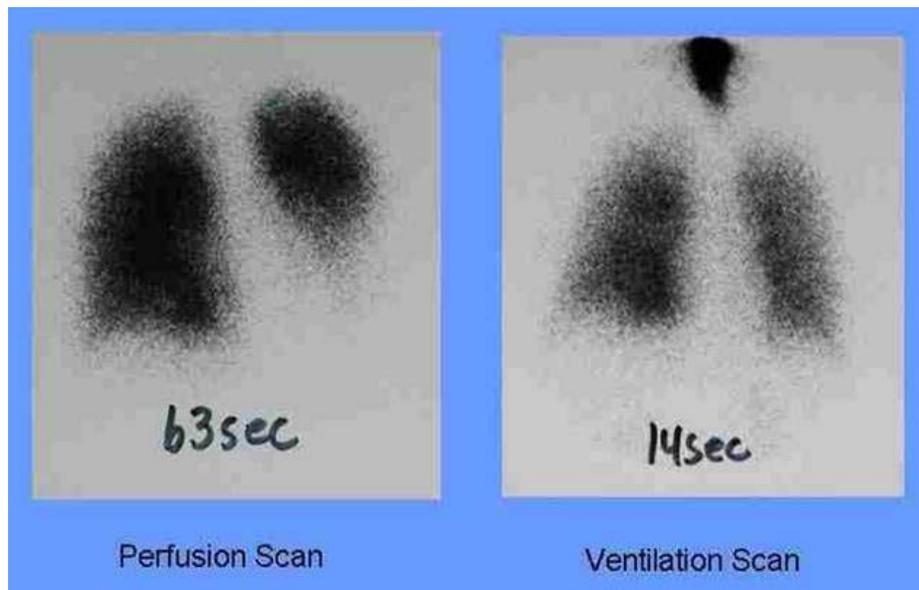

Fig. 12. Anterior views of perfusion and ventilation scans are shown here. A perfusion defect is present in the left lower lobe, but perfusion to this lobe is intact, making this a high-probability scan

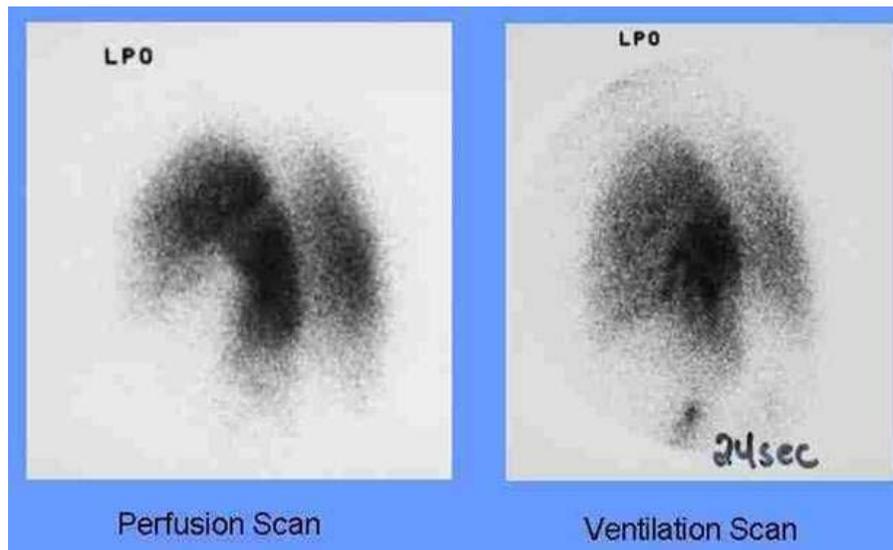

Fig. 13. A segmental ventilation perfusion mismatch evident in a left anterior oblique projection.

Noninvasive tests for lower extremity DVT

These may be helpful in the evaluation of patients who have nondiagnostic V/Q scan patterns of intermediate and low probability.

Color-flow Doppler imaging and compression ultrasonography have a high sensitivity (89-100%) and specificity (89-100%) for detection of proximal DVT in symptomatic patients. However, compression ultrasonography has a low sensitivity (38%) and a low positive predictive value (26%) in patients without symptoms of DVT. Patients with positive findings for DVT can be anticoagulated irrespective of their V/Q scan results; other patients must have more invasive investigations performed to definitively rule out pulmonary embolism.

Pulmonary angiography

Pulmonary angiography remains the criterion standard for the diagnosis of pulmonary embolism.

Following injection of iodinated contrast, anteroposterior, lateral, and oblique studies are performed on each lung.

Positive results consist of a filling defect or sharp cutoff of the affected artery. Nonocclusive emboli are described to have a tram-track appearance.

Abnormal findings on V/Q scans performed prior to angiography guide the operator to focus on abnormal areas.

Angiography generally is a safe procedure. The mortality rate for patients undergoing this procedure is less than 0.5%, and the morbidity rate is less than 5%.

Patients who have long-standing pulmonary arterial hypertension and right ventricular failure are considered high-risk patients.

Negative pulmonary angiogram findings, even if false negative, exclude clinically relevant pulmonary embolism.

Fig. 14. A pulmonary angiogram shows the abrupt termination of the ascending branch of the right upper-lobe artery, confirming the diagnosis of pulmonary embolism

Magnetic resonance imaging

With MRI, evidence of pulmonary emboli may be detected by using standard or gated spin-echo techniques.

Pulmonary emboli demonstrate increased signal intensity within the pulmonary artery. By obtaining a sequence of images, this signal that is originating from slow blood flow may be distinguished from pulmonary embolism. However, this remains a problem in pulmonary hypertension.

Magnetic resonance angiography is performed following intravenous administration of gadolinium. Gadolinium-based contrast agents (gadopentetate dimeglumine [Magnevist], gadobenate dimeglumine [MultiHance], gadodiamide [Omniscan], gadoversetamide [OptiMARK], gadoteridol [ProHance]) have been linked to the development of nephrogenic systemic fibrosis (NSF) or nephrogenic fibrosing dermopathy (NFD). The disease has occurred in patients with moderate to end-stage renal disease after being given a gadolinium-based contrast agent to enhance MRI or magnetic resonance angiography scans.

NSF/NFD is a debilitating and sometimes fatal disease. Characteristics include red or dark patches on the skin; burning, itching, swelling, hardening, and tightening of the skin; yellow spots on the whites of the eyes; joint stiffness with trouble moving or straightening the arms, hands, legs, or feet; pain deep in the hip bones or ribs; and muscle weakness.

MRI has a sensitivity of 85% and specificity of 96% for central, lobar, and segmental emboli; MRI is inadequate for the diagnosis of subsegmental emboli.

Echocardiography

This modality generally has limited accuracy in the diagnosis of pulmonary embolism.

Transesophageal echocardiography may identify central pulmonary embolism, and the sensitivity for central pulmonary embolism is reported to be 82%.

Overall sensitivity and specificity for central and peripheral pulmonary embolism is 59% and 77%.

Echocardiography may demonstrate right ventricular dysfunction in acute pulmonary embolism, predicting a higher mortality and possible benefit from thrombolytic therapy. Vanni et al reported that a right ventricular strain pattern is associated with a worse short-term outcome.

Medical Care

Immediate full anticoagulation is mandatory for all patients suspected to have deep vein thrombosis (DVT) or pulmonary embolism (PE). Diagnostic investigations should not delay empirical anticoagulant therapy. Current guidelines recommend starting unfractionated heparin (UFH), low molecular weight heparin (LMWH) or fondaparinux (all grade 1A) in addition to an oral anticoagulant (warfarin) at the time of diagnosis, and to discontinue UH, LMWH, or fondaparinux only after the international normalized ratio (INR) is 2.0 for at least 24 hours, but no sooner than 5 days after warfarin therapy has been started (grade 1C recommendation).³⁴ The recommended duration of UH, LMWH, and fondaparinux is based on evidence suggesting that the relatively long half-life of factor II, along with the short half-lives of protein C and protein S, may provoke a paradoxical hypercoagulable state if these agents are discontinued prematurely.

Thrombolytic therapy

Thrombolytic therapy should be considered for patients who are hemodynamically unstable, patients who have right-sided heart strain, and high-risk patients with underlying poor cardiopulmonary reserve.

Although most studies demonstrate superiority of thrombolytic therapy with respect to resolution of radiographic and hemodynamic abnormalities within the first 24 hours, this advantage disappears 7 days after treatment. Controlled clinical trials have not demonstrated benefit in terms of reduced mortality rates or earlier resolution of symptoms when currently compared with heparin.

Until randomized clinical trials demonstrate a clear morbidity or mortality benefit, the role of thrombolytic therapy in the management of acute pulmonary embolism remains controversial. The currently accepted indications for thrombolytic therapy include hemodynamic instability or right ventricular dysfunction demonstrated on echocardiography.

Goals of anticoagulation therapy

The efficacy of heparin therapy depends on achieving a critical therapeutic level of heparin within the first 24 hours of treatment. The critical therapeutic level of heparin is 1.5 times the baseline control value or the upper limit of normal range of the activated partial thromboplastin time (aPTT).

This level of anticoagulation is expected to correspond to a heparin blood level of 0.2-0.4 U/mL by the protamine sulfate titration assay and 0.3-0.6 by the antifactor X assay.

Each laboratory should establish the minimal therapeutic level for heparin, as measured by the aPTT, to coincide with a heparin blood level of at least 0.2 U/mL for each batch of thromboplastin reagent being used.

If intravenous UFH is chosen, an initial bolus of 80 U/kg or 5000 U followed by an infusion of 18 U/kg/h or 1300 U/h should be given, with the goal of rapidly achieving and maintaining the aPTT at levels that correspond to therapeutic heparin levels. Fixed-dose and monitored regimens of subcutaneous UFH are available and are acceptable alternatives.

Low molecular weight heparin

Current guidelines for patients with acute nonmassive pulmonary embolism recommend LMWH over UFH (grade 1A). In patients with massive pulmonary embolism, if concerns regarding subcutaneous absorption arise, severe renal failure exists, or if thrombolytic therapy is being considered, intravenous UFH is the recommended form of initial anticoagulation (grade 2C).³⁴

LMWHs have many advantages over UFH. These agents have a greater bioavailability, can be administered by subcutaneous injections, and have a longer duration of anticoagulant effect.

A fixed dose of LMWH can be used, and laboratory monitoring of aPTT is not necessary.

Trials comparing LMWH with UFH have shown that LMWH is at least as effective and as safe as UFH.

The studies have not pointed to any significant differences in recurrent thromboembolic events, major bleeding, or mortality between the 2 types of heparin.

LMWH can be administered safely in an outpatient setting. This has led to the development of programs in which clinically stable patients with pulmonary embolism are treated at home, at substantial cost savings.

Fondaparinux

Fondaparinux is a synthetic polysaccharide derived from the antithrombin binding region of heparin. Fondaparinux catalyzes factor Xa inactivation by antithrombin without inhibiting thrombin.

Fondaparinux has not been directly compared with subcutaneous UFH or LMWH, but one randomized open-label study of 2213 patients with symptomatic pulmonary embolism compared once daily subcutaneous fondaparinux with intravenous UFH. The 2 regimens were found to have similar rates of recurrent pulmonary embolism, bleeding, and death.³⁵

With the exception of patients presenting with massive pulmonary embolism (defined by hemodynamic compromise), LMWH or fondaparinux is recommended over intravenous UFH. This is because of a more predictable bioavailability, more rapid onset of full anticoagulant effect, and benefit of not typically needing to monitor anticoagulant effect.

However, in cases in which an anticoagulant with a shorter half-life is more desirable (ie, patients at particularly high risk of bleeding) or in patients with impaired renal function, intravenous UFH may be preferred (grade 2C).³⁴

Oral anticoagulant therapy

The anticoagulant effect of warfarin is mediated by the inhibition of vitamin K–dependent factors, which are II, VII, IX, and X. The peak effect does not occur until 36–72 hours after drug administration, and the dosage is difficult to titrate.

A prothrombin time ratio is expressed as an INR and is monitored to assess the adequacy of warfarin therapy. The recommended therapeutic range for venous thromboembolism is an INR of 2–3. This level of anticoagulation markedly reduces the risk of bleeding without the loss of effectiveness. Initially, INR measurements are performed on a daily basis; once the patient is stabilized on a specific dose of warfarin, the INR determinations may be performed every 1–2 weeks or at longer intervals.

Duration of anticoagulation

A patient with a first thromboembolic event occurring in the setting of reversible risk factors such as immobilization, surgery, or trauma, should receive warfarin therapy for at least 3 months. Among patients with idiopathic (or unprovoked) first events, 2 studies have compared 6 versus 3 months of anticoagulant therapy and no difference in the rate of recurrence was observed in either study.^{36,37} The current recommendation is anticoagulation for at least 3 months in these patients, and the need for extending the duration of anticoagulation should be reevaluated at that time.

Warfarin treatment for longer than 6 months is indicated in patients with recurrent venous thromboembolism or in those in whom a continuing risk factor for venous thromboembolism exists, including malignancy, immobilization, or morbid obesity.

Patients who have pulmonary embolism and preexisting irreversible risk factors, such as deficiency of antithrombin III, protein S and C, factor V Leiden mutation, or the presence of antiphospholipid antibodies, should be placed on long-term anticoagulation.

Compression stockings: For patients who have had a proximal DVT, elastic compression stockings with a pressure of 30-40 mm Hg at the ankle for 2 years following the diagnosis is recommended (grade 1A) to reduce the risk of postphlebotic syndrome.

Surgical Care

Indication of Surgical Removal of Thrombi

When acute pulmonary thromboembolism is diffuse, the bilateral main pulmonary arteries are rapidly occluded and most patients could die within hours after onset. Furthermore, many mortalities due to acute pulmonary thromboembolism are caused by circulatory collapse in the stage immediately after the onset and by early recurrence. Therefore, in cases of circulatory failure or shock the main objective of treatment is to recanalize the occluded pulmonary arteries as quickly as possible. Generally, the indications for pulmonary thrombectomy in this situation are (1) cases whose hemodynamics are extremely unstable and who do not respond to medication, (2) cases with angiogram or CT scan findings of obstructions over a wide area of the pulmonary arteries, (3) cases showing rapid progression of heart failure or respiratory failure, (4) cases in which thrombolytic therapy is contraindicated, and (5) cases with thrombi suspended from the right atrium to the right ventricle.

Many cases that fall into sudden shock before this disease is diagnosed cannot be operated on. Postoperative cases or long-term clinical patients who experience sudden dyspnea or who show signs of hypoxemia or right ventricular dilatation in their echocardiograms should be suspected of acute pulmonary thromboembolism, and percutaneous cardiopulmonary support (PCPS) should start immediately at the bedside. Furthermore, if there are no fatal cerebrovascular complications, and circulatory collapse due to the thromboembolism is identified, pulmonary artery thrombectomy should be carried out. Patients may include some who have thromboembolism (subacute pulmonary thromboembolism) of more than 2 weeks duration. Such cases are difficult to treat with conventional thrombectomy and should be diagnosed and their surgical indication determined with care.

Surgical Treatment of Acute Pulmonary Thromboembolism

Surgical treatment of this condition involves removal of the thromboemboli by transvenous thrombectomy or open thrombectomy.

Transvenous Thrombectomy (Catheter Intervention)

This is a method whereby the thromboemboli are removed by suction using a catheter inserted transvenously into the pulmonary artery. Catheters used in this method are the Greenfield catheter, guiding catheter for percutaneous transluminal coronary angioplasty (PTCA), and the HYDROLYSER embolectomy catheter. This method can be used for patients in whom thrombolytic therapy is contraindicated, and there are many reports, such as that of Greenfield et al. , of its efficacy. Still, because of the ever-present danger of circulatory collapse, transvenous embolectomy should be carried out under conditions where open embolectomy or PCPS is possible.

Open Thrombectomy

With extracorporeal circulation using an artificial heart-lung, namely under cardiopulmonary bypass, the pulmonary artery is opened and the thromboemboli are removed. If the patient has respiratory failure or poor hemodynamics preoperatively, extracorporeal circulation is quickly initiated using the femoral artery and vein. In cases of shock in the ward where hemodynamics cannot be maintained, the patient is transported to the operating room with PCPS. In cases of circulatory collapse with this disease, the speed of initiation of extracorporeal circulation is the key determinant of survival.

As for the surgical technique, extracorporeal circulation is initiated after median sternal incision, incisions are made bilaterally in the main pulmonary arteries, and open thrombectomy is carried out. Thrombi of acute pulmonary thromboembolism

cases, in contrast to the organized thrombi of chronic cases, are soft and rod shaped, and the removed thrombi are relatively new and red. Although it is preferable to remove the thrombi as peripherally as possible, remaining thrombi can be treated postoperatively by thrombolytic methods if the major central thrombi have been removed. If they include those of more than 2 weeks duration (subacute pulmonary thromboembolism) that are firmly attached to the pulmonary arterial wall, care must be taken not to injure the arterial wall during the thrombectomy. The surgery can take place with the heart beating, but cardiac arrest is recommended for cases with multiple small thrombi in the segmental arteries or cases with thrombi firmly attached to the arterial wall.

The current grade 1A recommendation is that patients with acute pulmonary embolism should not routinely receive vena cava filters in addition to anticoagulants.

Inferior vena cava (IVC) interruption by the insertion of an IVC filter (Greenfield filter) is only indicated in the following settings:

Patients with acute venous thromboembolism who have an absolute contraindication to anticoagulant therapy (eg, recent surgery, hemorrhagic stroke, significant active or recent bleeding)

Patients with massive pulmonary embolism who survived but in whom recurrent embolism invariably will be fatal

Patients who have objectively documented recurrent venous thromboembolism, adequate anticoagulant therapy notwithstanding

An ideal IVC filter should have the following characteristics³⁸ :

Easy and safe placement by percutaneous technique

Biocompatible and mechanically stable

Ability to trap emboli without causing occlusion of the vena cava

One large trial has shown that during the first 12 days after insertion of IVC filters, significantly fewer patients had recurrent pulmonary embolism. However, following a 2-year follow-up, no significant differences in survival rates existed between the 2 groups. Furthermore, significantly higher rates of recurrent DVT occurred among patients who received an IVC filter. Other complications of IVC filters include proximal migration of the filter into the right-sided heart chambers and perforation of the IVC.

Temporary inferior vena cava

Bleeding/hematoma at puncture site: 16 (27.5%)
 Thrombolysis for intrafilter thrombus: 7 (12.1%)
 Slight fever: 6 (9.7%)
 Retroperitoneal hematoma [percutaneous cardiopulmonary support (PCPS) site]: 1 (1.7%)
 IVC occlusion: 1 (1.7%)
 Filter migration: 1 (1.7%)
 Pneumothorax: 0 (0%)

Complications of temporary IVC filter

aPE may recur asymptotically, and aPE recurrence has no specific symptoms. Even if any symptoms appear and are recorded by echocardiography, blood flow scintigraphy, CT, etc., similar records of the patient immediately before the events must be available for comparison to confirm that they are indeed symptoms of recurrence. That would be impossible, and there are many obstacles to obtaining an accurate recurrence rate. We therefore evaluated symptoms that appeared anew during acute-stage management of aPE which, although not perfect, are highly reliable indicators of aPE recurrence.

The results suggested that tIVCF users present fewer new symptoms during use and are easier to control. The tIVCF user who had a recurrence and died had a giant ovarian cancer with the tip of the tumor extending to the epigastrium. The inferior vena cava was extruded directly below the diaphragm by the tumor, and the tIVCF had to be placed inside the flattened inferior vena cava. When the Neuhaus Protect, which is made of Teflon, is dilated inside a flattened inferior vena cava it is easily distorted, so its

ability to capture thrombi must have been compromised. On the other hand, we thought it was highly probable that a metallic tIVCF would injure the vascular wall and decided against it. Secondary prevention in cases like this is considered to be an important issue for the future.

The most frequent complication of tIVCF was bleeding/hematoma of the puncture site. Because the basic treatments for aPE are anticoagulant therapy and fibrinolytic therapy, and the shaft of the tIVCF is extracorporeal, caution is constantly required to prevent this complication. The best way to prevent it is to improve the attending clinician's technique and to puncture the vein at the first attempt. The complications that are generally cited in connection with tIVCF use are hemorrhagic complications caused by basic aPE therapy, filter displacement, venous thrombus, infections, air embolism, and filter breakage. Thrombus in the filter site is another complication that should be considered. When contrast radiography of the filter site at the time of removal revealed a thrombus occupying more than one-fourth of the lumen, we administered fibrinolytic treatment from the filter tip. The thrombus size was reduced in all cases, and the filter could be removed in a few days without any problems.

The major reason for using a pIVCF was poor ADL in the tIVCF users and APE recurrence in the nonusers. ADL is determined by the underlying disease condition and poor ADL is a major risk factor for DVT, so the use of pIVCF was inevitable in such cases. pIVCF use due to aPE recurrence could be avoided by using tIVCF, which is considered to be clinically effective in acute-stage control.

The basic principle of aPE prevention is extended ADL. Long-term bed rest slows the venous blood flow rate and encourages the formation of venous thrombi, so it should be avoided as much as possible. Although recurrence could easily occur when shifting from bed rest to expanded ADL, we believe that if unstable DVT entering the venous bloodstream are captured by the tIVCF, expanded ADL can proceed safely in the acute phase.

As retrievable filters that can be removed with certainty are developed in the future, we can look forward to fewer complications of bleeding and infections and the realization of aPE acute-stage management that is safer than ever before.

Activity

Activity is recommended as tolerated. Early ambulation is recommended over bed rest when feasible (grade 1A recommendation).

Medication

Immediate therapeutic anticoagulation is initiated for patients with suspected deep venous thrombosis (DVT) or pulmonary embolism (PE). Anticoagulation therapy with heparin reduces mortality rates from 30% to less than 10%. Thrombolytic therapy is recommended for 3 groups of patients: (1) those patients who are hemodynamically unstable, (2) those who have right-sided heart strain, and (3) those who have limited cardiopulmonary reserve.

Chronic anticoagulation is critical to prevent relapse of DVT or pulmonary embolism following initial heparinization. The optimum duration of anticoagulation has not been well studied and is controversial. The general consensus is that a significant reduction in recurrence is associated with 3-6 months of anticoagulation.

Thrombolytics

Thrombolysis is indicated for hemodynamically unstable patients with pulmonary embolism. Thrombolysis dramatically improves acute cor pulmonale. Thrombolytic therapy has replaced surgical embolectomy as the treatment for hemodynamically

unstable patients with massive pulmonary embolism.

Thrombolytic regimens currently in use for pulmonary embolism include 2 forms of recombinant tissue-plasminogen activators, alteplase (t-PA) and reteplase (r-PA), along with urokinase and streptokinase. The comparative clinical trials have shown that administration of a 1-h infusion of alteplase is more rapidly effective than urokinase or streptokinase over a 12-h period. The safety and efficacy of different thrombolytic agents is comparable. Streptokinase may cause anaphylaxis, hypotension, and other adverse reactions, leading to the cessation of therapy in many cases.

Wang et al conducted a prospective, randomized, multicenter trial in 118 patients with acute pulmonary thromboembolism (PTE) and either hemodynamic instability or massive pulmonary artery obstruction. 40 Patients were randomly assigned to receive either alteplase (rt-PA) at 50 mg IV infused over 2 h (n = 65) or the current FDA-approved dose of 100 mg IV infused over 2 h (n = 53). Efficacy was measured by improvements of right ventricular dysfunction (RVD) on echocardiograms, lung perfusion defects on ventilation perfusion lung scans, and pulmonary artery obstructions on CT angiograms. Adverse events, including death, bleeding, and PTE recurrence, were also evaluated.

Progressive improvements in RVDs, lung perfusion defects, and pulmonary artery obstructions were found to be similarly significant in both treatment groups. No difference in outcome was observed for patients with hemodynamic instability or massive pulmonary artery obstruction. Three (6%) patients in the 100-mg group and 1 (2%) in the 50-mg group died as the result of either PTE or bleeding. The 50-mg regimen resulted in less bleeding tendency than the 100 mg/2 h regimen (3% vs 10%), especially in patients with a body weight of less than 65 kg (14.8% vs 41.2%, $P = .049$). Fatal recurrent PTE did not occur in either group.

Rarely, empiric thrombolysis may be indicated in selected patients who are hemodynamically unstable, eg, the clinical likelihood of pulmonary embolism is overwhelming and the patient's condition is rapidly deteriorating (with the possibility of imminent death). In such patients, the possible risk of severe complications from thrombolysis should be carefully evaluated against the potential benefits.

Reteplase (Retavase)

Second-generation recombinant plasminogen activator that forms plasmin after facilitating cleavage of endogenous plasminogen. In clinical trials, shown to be comparable to t-PA in achieving TIMI, 2 or 3 patency, at 90 min. Given as a single bolus or as 2 boluses administered 30 min apart.

As a fibrinolytic agent, seems to work faster than its forerunner, t-PA, and may be more effective in patients with larger clot burdens. Also reported to be more effective than other agents in lysis of older clots. Two major differences help explain these improvements. Compared with t-PA, r-PA does not bind fibrin so tightly, allowing the drug to diffuse more freely through the clot. Another advantage seems to be that it does not compete with plasminogen for fibrin-binding sites, allowing plasminogen at the site of the clot to be transformed into clot-dissolving plasmin.

The FDA has not approved r-PA for use in patients with PE. Studies for PE have used the same dose approved by the FDA for coronary artery fibrinolysis.

Alteplase (Activase)

Used in management of AMI, acute ischemic stroke, and PE. Drug most often used to treat patients with PE in the ED. Usually given as a front-loaded infusion over 90-120 min. FDA-approved for this indication. Most ED personnel are familiar with its use because it is widely used for treatment of patients with AMI. An accelerated 90-min regimen is widely used, and most believe it is both safer and more effective than the approved 2-h infusion. Accelerated regimen dose is based on patient weight.

Heparin therapy should be instituted or reinstated near the end of or immediately following infusion, when the aPTT or

thrombin time returns to twice normal or less.

Urokinase (Abbokinase)

Direct plasminogen activator produced by human fetal kidney cells grown in culture. Acts on the endogenous fibrinolytic system and converts plasminogen to the enzyme plasmin, which, in turn, degrades fibrin clots, fibrinogen, and other plasma proteins. Advantage is that this agent is nonantigenic; however, more expensive than streptokinase and, thus, limits use. When used for localized fibrinolysis, given as local catheter-directed continuous infusion directly into area of thrombus with no loading dose. When used for PE, loading dose is necessary.

Streptokinase (Kabikinase, Streptase)

Acts with plasminogen to convert plasminogen to plasmin. Plasmin degrades fibrin clots, fibrinogen, and other plasma proteins. Increase in fibrinolytic activity that degrades fibrinogen levels for 24-36 h takes place with IV infusion of streptokinase. Highly antigenic. Highly likely that treatment will be interrupted due to allergic drug reactions.

Chills, fever, nausea, and skin rashes are frequent (up to 20%). Blood pressure and heart rate drop in approximately 10% of cases during or shortly after treatment.

Late complications may include purpura, respiratory distress syndrome, serum sickness, Guillain-Barré syndrome, vasculitis, and renal or hepatic dysfunction.

Anticoagulants

Heparin augments activity of the natural anticoagulant antithrombin III and prevents conversion of fibrinogen to fibrin. Full-dose LMWH or unfractionated IV heparin should be initiated at the first suspicion of DVT or pulmonary embolism. Heparin does not dissolve an existing clot, but it does prevent clot propagation and embolization. Recurrence or extension of DVT and pulmonary embolism may occur despite therapeutic anticoagulation with heparin.

With proper dosing, several LMWH products have been found to be safer and more effective than UFH for prophylaxis and treatment of patients with DVT and pulmonary embolism. Not necessary or useful to monitor aPTT while using LMWH. Drug is most active in tissue phase, and, as opposed to UFH, LMWH does not exert most of its effects on coagulation factor IIa.

Many different LMWH products are currently available. Because of the pharmacokinetic differences, dosing and interval of administration is highly product-specific. Presently, 3 LMWH products are available in the United States (enoxaparin, dalteparin, ardeparin). Enoxaparin is the only one that is approved by the FDA for treatment of patients with DVT. The FDA has approved all 3 for DVT prophylaxis at a lower dose. LMWH administered via subcutaneous route is preferred for commencing anticoagulation therapy. Maintenance therapy with warfarin usually is initiated simultaneously. The weight-adjusted heparin dosing regimens have proven to be efficacious for treatment of patients with DVT and pulmonary embolism and are endorsed by the experts.

Enoxaparin (Lovenox)

Enhances inhibition of factor Xa and thrombin by increasing antithrombin III activity. In addition, preferentially increases inhibition of factor Xa. First LMWH in United States. Only LMWH approved by FDA for treatment and prophylaxis of DVT and PE. Widely used in pregnancy, although clinical trials are not yet available to demonstrate that it is as safe as UFH.

Dalteparin (Fragmin)

LMWH with many similarities to enoxaparin but with a different dosing schedule. Approved for DVT prophylaxis in patients undergoing abdominal surgery. Except in overdoses, no utility exists in checking PT or aPTT because aPTT does not correlate with anticoagulant effect of fractionated LMWH.

Ardeparin (Normiflo)

LMWH recently released in United States for DVT prophylaxis in patients undergoing hip and knee surgery. Except in overdoses, no utility exists in checking PT or aPTT because the aPTT does not correlate with anticoagulant effect of fractionated LMWH.

Heparin (Hep-Lock, Liquaemin)

Augments activity of antithrombin III and prevents conversion of fibrinogen to fibrin. Does not actively lyse but is able to inhibit further thrombogenesis. Prevents reaccumulation of clot after spontaneous fibrinolysis. When UFH is used, the aPTT should not be checked until 6 h after the initial heparin bolus because an extremely high or low value during this time should not provoke any action.

Interferes with hepatic synthesis of vitamin K–dependent coagulation factors. Used for prophylaxis and treatment of venous thrombosis, PE, and thromboembolic disorders. Never administer to patients with thrombosis until after fully anticoagulated with heparin (first few days of warfarin therapy produce a hypercoagulable state). Failing to anticoagulate with heparin before starting warfarin causes clot extension and recurrent thromboembolism in approximately 40% of patients, compared with 8% of those who receive full-dose heparin before starting warfarin. Heparin should be continued for the first 5-7 d of oral warfarin therapy, regardless of the PT time, to allow time for depletion of procoagulant vitamin K–dependent proteins.

Tailor dose to maintain an INR in the range of 2.5-3.5. Risk of serious bleeding (including hemorrhagic stroke) is approximately constant when the INR is 2.5-4.5 but rises dramatically when the INR is >5. In the United Kingdom, higher INR target of 3-4 often is recommended.

Evidence suggests that 6 mo of anticoagulation reduces rate of recurrence to half of the recurrence rate observed when only 6 wk of anticoagulation is given. Long-term anticoagulation is indicated for patients with an irreversible underlying risk factor and recurrent DVT or recurrent PE.

Procoagulant vitamin K–dependent proteins are responsible for a transient hypercoagulable state when warfarin is first started and stopped. This is the phenomenon that occasionally causes warfarin-induced necrosis of large areas of skin or of distal appendages. Heparin is always used to protect against this hypercoagulability when warfarin is started; but, when warfarin is stopped, the problem resurfaces, causing an abrupt temporary rise in the rate of recurrent venous thromboembolism.

At least 186 different foods and drugs reportedly interact with warfarin. Clinically significant interactions have been verified for a total of 26 common drugs and foods, including 6 antibiotics and 5 cardiac drugs. Every effort should be made to keep the patient adequately anticoagulated at all times because procoagulant factors recover first when warfarin therapy is inadequate.

Patients who have difficulty maintaining adequate anticoagulation while taking warfarin may be asked to limit their intake of foods that contain vitamin K.

Foods that have moderate to high amounts of vitamin K include Brussels sprouts, kale, green tea, asparagus, avocado, broccoli, cabbage, cauliflower, collard greens, liver, soybean oil, soybeans, certain beans, mustard greens, peas (black-eyed peas, split peas, chick peas), turnip greens, parsley, green onions, spinach, and lettuce.

Fondaparinux sodium (Arixtra)

Synthetic anticoagulant that works by inhibiting factor Xa, a key component involved in blood clotting. Provides highly predictable response. Bioavailability is 100%. Has a rapid onset of action and a half-life of 14-16 h, allowing for sustained

antithrombotic activity over 24-h period. Does not affect prothrombin time or activated partial thromboplastin time, nor does it affect platelet function or aggregation.

Deterrence/Prevention

Heparin prophylaxis

The incidence of venous thrombosis, pulmonary embolism (PE), and death can be significantly reduced by embracing a prophylactic strategy in high-risk patients. Prevention of deep vein thrombosis (DVT) in the lower extremities inevitably reduces the frequency of pulmonary embolism; therefore, populations at risk must be identified, and safe and efficacious prophylactic modalities should be used. The risk groups identified in clinical practice and the prophylaxis recommended by the Sixth Consensus Conference on Antithrombotic Therapy are described in the Table.

Prophylaxis Against Venous Thromboembolism

Condition	Risk (% P)	General Surgery	Recommendations
Low risk	3	(1) Early ambulation	
Moderate risk	29	(1) Unfractionated heparin: 5000 U OC given 2 h preoperatively and q12h postoperatively (2) Dalteparin: 2500 U 1-2 hr before surgery, then once daily Enoxaparin: 2000 U before surgery, then once daily Nadroparin: 3100 U 2 hr before surgery, then once daily Tinzaparin: 3500 U 2 hr before surgery, then once daily	
High risk	39	(1) Unfractionated heparin: 5000 U OC given 2 h preoperatively and q12h postoperatively (2) Dalteparin: 5000 U 10-12 hr before surgery, then once daily Enoxaparin: 4000 U 10-12 hr before surgery, then once daily	
Very high risk	80	(1) Unfractionated heparin: 5000 U OC given 2 h preoperatively and q12h postoperatively; dalteparin: 2500 U given 2 h preoperatively and q6; plus, intermittent pneumatic compression applied intraoperatively (2) Dalteparin: 5000 U 10-12 hr before surgery, then once daily Enoxaparin: 4000 U 10-12 hr before surgery, then once daily (3) Perioperative warfarin: INR 2-3	
Orthopedic Surgery/Neurological Surgery/Trauma			
Total hip replacement	51	(1) Dalteparin: 5000 U 1-2 hr before surgery, then once daily Enoxaparin: 3000 U 10-12 hr before surgery, then once daily Nadroparin: 40 U/kg 2 hr before surgery, then once daily Tinzaparin: 50 U/kg 2 hr before surgery, then 75 U/kg once daily (2) Warfarin: Preoperatively and adjusted to INR of 2-3 postoperatively, continue up to 4 wk after surgery	
Total knee replacement	61	(1) Dalteparin: 5000 U 1-2 hr before surgery, then once daily Enoxaparin: 3000 U 10-12 hr before surgery, then once daily Nadroparin: 40 U/kg 2 hr before surgery, then once daily Tinzaparin: 50 U/kg 2 hr before surgery, then 75 U/kg once daily (2) Warfarin: Preoperatively and adjusted to INR of 2-3 postoperatively, continue up to 4 wk after surgery	
Hip fracture surgery	46	(1) Dalteparin: 5000 U 1-2 hr before surgery, then once daily Enoxaparin: 3000 U 10-12 hr before surgery, then once daily Nadroparin: 40 U/kg 2 hr before surgery, then once daily Tinzaparin: 50 U/kg 2 hr before surgery, then 75 U/kg once daily (2) Warfarin: Preoperatively and adjusted to INR of 2-3 postoperatively, continue up to 4 wk after surgery	
Neurosurgery	24	(1) Intermittent pneumatic compression (2) Unfractionated heparin: 5000 U OC q12h and intermittent pneumatic compression for high-risk patients	
Acute spinal cord injury with leg paralysis	40	(1) Unfractionated heparin: OC in doses adjusted to paralytic produce aPTT = 1.5 × control 6 h after dose (2) Enoxaparin: 3000 U twice daily (3) Warfarin: Adjusted to INR of 2-3 in rehabilitation phase (4) Intermittent pneumatic compression plus unfractionated heparin: 5000 U OC q12h	
Multiple trauma	53	(1) Intermittent pneumatic compression until further bleeding is unlikely; then, give (2) Enoxaparin: 30 mg OC q12h or (3) Warfarin: Adjusted to INR of 2-3	
Medical Conditions			
Acute myocardial infarction	24	Unfractionated heparin: 5000 U OC q12h unless therapeutic anticoagulation used	
Ischemic stroke with paralysis	42	Unfractionated heparin: 5000 U OC q12h	
Medical patients (cancer, bedrest, congestive heart failure, severe lung disease)	20	(1) Unfractionated heparin: 5000 U OC q12h (2) Dalteparin: 2500 U once daily Enoxaparin: 2000 U once daily	

Sequential compression devices

Compression stockings provide a compression of 30-40 mm Hg gradient and are a safe and effective therapy to prevent venous thromboembolism in patients who are at high risk when heparin therapy is not desirable or is contraindicated. These devices provide a gradient of compression that is highest at the toes and gradually decreases to the level of the thigh. This mechanism reduces the capacitative venous volume by approximately 70% and increases the measured velocity of blood flow by a factor of 5 or more in lower extremity veins.

A meta-analysis calculated a DVT risk ratio of 0.28 for gradient compression stockings (compared with no prophylaxis) in patients undergoing abdominal surgery, gynecologic surgery, or neurosurgery. Other studies have reported that gradient

compression stockings and low molecular weight heparin (LMWH) were the most effective modalities in reducing the incidence of DVT after hip surgery.

The universal white stockings, known as antiembolic stockings or Ted stockings, produce a maximum compression of only 18 mm Hg. Ted stockings rarely are fitted in such a way as to provide adequate gradient compression to the deep venous system. Therefore, Ted stockings have no proven efficacy in the prevention of DVT and pulmonary embolism.

Gradient compression pantyhose (30-40 mmHg) are available in pregnant sizes. They are recommended by many specialists for all women who are pregnant because they prevent DVT and reduce or prevent the development of varicose veins.

Although strict bed rest was recommended in the past for acute DVT to reduce the risk of pulmonary embolism, a study has shown no benefit from prescribing bed rest. Therefore, strict bed rest for 5 days is not justified if adequate therapy with LMWH and adequate compression is assured.

Complications

Sudden cardiac death

Obstructive shock

Pulseless electrical activity

Atrial or ventricular arrhythmias

Secondary pulmonary arterial hypertension

Cor pulmonale

Severe hypoxemia

Right-to-left intracardiac shunt

Lung infarction

Pleural effusion

Paradoxical embolism

Prognosis

The prognosis of patients with pulmonary embolism depends on 2 factors: (1) the underlying disease state and (2) appropriate diagnosis and treatment.

Most patients treated with anticoagulants do not develop long-term sequelae upon follow-up evaluation.

At 5 days of anticoagulant therapy, 36% of lung scan defects are resolved; at 2 weeks, 52% are resolved; at 3 months, 73% are resolved.

The mortality rate in patients with undiagnosed pulmonary embolism is 30%.

Elevated plasma levels of natriuretic peptides (brain natriuretic peptide and N-terminal pro-brain natriuretic peptide) have been associated with higher mortality in patients with pulmonary embolism.⁴¹ In one study, levels of N-terminal pro-brain natriuretic peptide greater than 500 ng/L was independently associated with central pulmonary embolism and was a possible predictor of death from pulmonary embolism.

In the Prospective Investigation of Pulmonary Embolism Diagnosis (PIOPED) (PIOPED) study, the 1-year mortality rate was 24%.⁷ The deaths occurred due to cardiac disease, recurrent pulmonary embolism, infection, and cancer.

The risk of recurrent pulmonary embolism is due to the recurrence of proximal venous thrombosis; approximately 17% of patients with recurrent pulmonary embolism were found to have proximal DVT.

In a small proportion of patients, pulmonary embolism does not resolve; hence, chronic thromboembolic pulmonary arterial hypertension results.

Medicolegal Pitfalls

Pulmonary embolism (PE) is an extremely common disorder. It presents with nonspecific clinical features and requires specialized investigations for confirmation of diagnosis. Therefore, many patients die from unrecognized pulmonary embolism. The other common pitfalls are as follows:

- Disregarding patient's complaints of unexplained dyspnea as anxiety or hyperventilation

- Blaming complaints of unexplained chest pain on musculoskeletal pain

- Failing to recognize, diagnose, and treat deep vein thrombosis (DVT)

- Failing to initiate an appropriate diagnostic workup in patients with symptoms consistent with pulmonary embolism

- Failing to initiate therapeutic anticoagulant therapy with heparin in patients suspected to have pulmonary embolism, before the V/Q scan or other investigations

The role of thrombolytic therapy in patients who are hemodynamically stable remains uncertain. No particular diagnostic strategy appears to be superior to another at present. More clinical studies are needed to evaluate the utility of new diagnostic approaches for pulmonary embolism. The availability of the diagnostic tests, the expertise of the radiologists, cost-effective analysis, and local traditions appear to be the considerations in the workup of a patient suspected to have pulmonary embolism.

Special Concerns

Pregnancy

The risk of venous thromboembolism is increased during pregnancy and the postpartum period. Pregnant women who are in a hypercoagulable state or have had previous venous thromboembolism should receive prophylactic anticoagulation during pregnancy.

Pulmonary embolism is the leading cause of death in pregnancy. Guidelines by the professional societies make this difficult diagnosis easier and reduce the risks of radiation to the fetus. If the patient has a low pretest probability for pulmonary embolism and a normal D-dimer test result, clinical exclusion from further investigations is recommended. When the suspicion is high, the patients should have bilateral leg Doppler assessment. If the results are positive, the patient should be treated for pulmonary embolism. If the results are negative, CT pulmonary angiography is the next step. To rule out contrast-induced hypothyroidism, all neonates exposed to the iodinated contrast in utero should have their serum thyrotropin level checked in the first week of life.

Pregnant patients diagnosed with DVT or pulmonary embolism are treated with unfractionated heparin or LMWH throughout their pregnancy. Warfarin is contraindicated because it crosses the placental barrier and can cause fetal malformations. Therefore, either subcutaneous unfractionated heparin or LMWH at full anticoagulation doses should be continued until delivery. Women experiencing a thromboembolic event during pregnancy should receive therapeutic treatment with unfractionated heparin or LMWH during pregnancy, with anticoagulation continuing for 4-6 weeks postpartum, and for a total of at least 6 months.

Heparin-induced thrombocytopenia

Heparin-induced thrombocytopenia (HIT) is a transient prothrombotic disorder initiated by heparin.

Main features are (1) thrombocytopenia resulting from immunoglobulin G-mediated platelet activation and (2) in vivo thrombin generation and increased risk of venous and arterial thrombosis.

The highest frequency of HIT, 5%, has been reported in post-orthopedic surgery patients receiving up to 2 weeks of unfractionated heparin. HIT occurred in approximately 0.5% of post-orthopedic surgery patients receiving LMWH for up to 2 weeks.

HIT may manifest clinically as extension of the thrombus or formation of new arterial thrombosis. HIT should be suspected whenever the patient's platelet count falls to less than 100,000/ μ L or less than 50% of the baseline value, generally after 5-15 days of heparin therapy. The definitive diagnosis is made by performing a platelet activation factor assay.

The treatment of patients who develop HIT is to stop all heparin products, including catheter flushes and heparin-coated catheters, and to initiate an alternative nonheparin anticoagulant, even when thrombosis is not clinically apparent. Preferred agents include direct thrombin inhibitors such as lepirudin or argatroban. Start warfarin while the patient receives an alternative nonheparin anticoagulant and only when the platelet count has recovered to at least 100,000/ μ L, preferably 150,000/ μ L.

Resistance to heparin

Few patients with venous thromboembolism require large doses of heparin for achieving an optimal activated partial thromboplastin time (aPTT). These patients have increased plasma concentrations of factor VIII and heparin-binding proteins. Increased factor VIII concentration causes a dissociation between aPTT and plasma heparin values. The aPTT is suboptimal, but patients have adequate heparin levels upon protamine titration. This commonly occurs in patients with a concomitant inflammatory disease.

Monitoring the antifactor Xa assay results in this situation is safe and effective and results in less escalation of the heparin dose when compared with monitoring with aPTT. Whenever a therapeutic level of aPTT cannot be achieved with large doses of unfractionated heparin administration, either determination of plasma heparin concentration or therapy with LMWH should be instituted.

Elderly individuals

Pulmonary embolism is increasingly prevalent among elderly patients, yet the diagnosis is missed more often in this population because respiratory symptoms often are dismissed as being chronic.

Even when the diagnosis is made, appropriate therapy frequently is inappropriately withheld because of bleeding concerns.

An appropriate diagnostic workup and therapeutic anticoagulation with a careful risk-to-benefit assessment is recommended in this patient population.

Future research

The advances over the past several decades have significantly improved diagnostic abilities and have refined the treatment of patients with pulmonary embolism. However, several areas need further research and properly conducted therapeutic trials. The role of LMWH and the optimal duration of anticoagulant therapy in different subgroups of patients with venous thromboembolism require further study.

Future studies should determine whether less intense warfarin therapy (international normalized ratio [INR] less than 2), which will result in less bleeding, is effective in preventing recurrences.

Whether drugs that inhibit the action of thrombin (eg, hirudin) are useful in treating patients with venous thromboembolic

disease needs to be determined by future trials.

TOPIC 10. VASCULAR INJURY

VASCULAR INJURIES IN THE ARM

Arteries and veins in the arms are the second most common location for vessel injuries in the body and constitute almost half of all peripheral vascular injuries. Much more often than in the legs they occur together with neurological and skeletal injuries. Although vascular injuries in the arms rarely lead to fatal or serious bleeding, ischemic consequences are common. The extensive collateral network around the elbow makes clinical signs variable and often minute. On the other hand, if the brachial artery is obstructed proximal to the origin of the deep brachial artery, the risk for amputation is substantial: up to 50% of such patients lose the arm if the vessel is not repaired. While the vascular injury per se often can be managed easily, it is the damaged nerves that cause the main functional disturbances in the long run.

Because arm vessel trauma is common and sometimes appear without signs and symptoms, missed injuries cause considerable morbidity in trauma patients. Awareness and optimal management may reduce this morbidity. The arteries supplying blood to the arms – the subclavian and axillary arteries – are located in the thorax or thoracic outlet, and if these vessels are traumatized, the consequences are often more serious.

Etiology and Pathophysiology

Injury mechanisms are the same in the arms and legs, and the brachial, radial, and ulnar arteries can be damaged by both penetrating and blunt trauma. Knives and gunshots usually cause penetrating injuries (most often to the brachial artery), but lacerations secondary to fractures occur regularly. Sharp fragments commonly penetrate vessel walls (Fig. 1).

Fig. 1. Angiography showing an occluded brachial artery severed by the sharp ends of a shaft fracture of the humerus

Blunt injuries occur in road traffic accidents because of fractures and joint dislocations. The most frequent orthopedic arm injuries associated with vessel damage are listed in Table 1.

Table 1. Most common sites for combined orthopedic and vascular injury

Orthopedic injury	Vascular injury
Fractured clavicle	Subclavian artery
Shoulder dislocation	Axillary artery
Supracondylar fracture of the humerus	Brachial artery
Elbow dislocation	Brachial artery

There are also types of trauma specific for arm vessel injuries. A large number of upper limb vascular trauma are caused by industrial and domestic accidents. Splintered glass as well as self-in-flicted wounds regularly damage vessels below the elbow. The popularity of using the brachial artery as a site for vascular access for endovascular procedures has caused an increase in iatrogenic catheter-related injuries to the brachial artery in proximity to the elbow. Pseudoaneurysms are often caused by radial artery punctures for arterial blood samples.

As in all traumatized vessels, transection or laceration may cause bleeding, thrombosis, or both. Transections, intimal tears, and contusions are more frequent after blunt trauma. Tissue in the distal parts of the arm is as susceptible to ischemia as in the legs, and the time limit of 6–8h before irreversible damage occurs is also valid for arm injuries. Concomitant nerve injuries, as mentioned, are the main cause of morbidity long term. Such injuries are equally common after penetrating and blunt trauma. In the literature, 35–60% of arterial injuries in the upper arm are associated with nerve injuries, and over 75% are associated with nerve, bone, or venous damage.

Clinical Presentation

Medical History

Patients with vascular injuries in the arms arrive at the emergency department after accidents, knife or shooting assaults, or car crashes causing multiple injuries. As with all injuries, it is important to interview the rescue personnel and accompanying persons about the type of injury and the type of bleeding. The exact time of the injury should be established to facilitate planning of repair. Because orthopedic injuries are associated with arterial damage, it

is also essential to ask whether joint dislocations or fractures were noted or reduced. Complaints of pain from areas around a joint indicate a possible luxation. Even more important is to ask for symptoms of nerve damage, including permanent or transient numbness and impaired motor function in any part of the arm.

Clinical Signs and Symptoms

Both the “hard” and the “soft” signs of vascular trauma occur after upper extremity vascular injuries. Examples, in descending frequency of occurrence, include diminished or absent radial pulse, motor deficit, sensory loss, hemorrhage, and expanding hematoma. It is common for a diminished radial pulse or an abnormal brachial blood pressure to be the only sign of vascular obstruction. Because pulse wave propagation through a thrombus is possible, a palpable radial pulse does not completely exclude arterial obstruction; therefore, a high suspicion of arterial injury is necessary even when a palpable pulse is found. As a guideline, a difference of more than 20 mmHg in blood pressure between the arms should make the examiner suspect a vascular injury. Inability to move the fingers, hands, and arms as well as disturbances in sensation are frequently associated with vascular injury. The sensory and motor functions must therefore be carefully examined and evaluated to disclose any nerve damage that should be repaired. A list of what this examination should cover is given in Table 2. In unconscious patients, this examination is the only way to reveal indications of arterial damage.

Diagnostics

Investigations beyond the physical examination of the patient should be done only in stable patients. Accordingly, most patients with distal arm injuries can undergo angiography or duplex scanning provided that these investigations do not delay treatment. Arteriography is indicated when arterial involvement is not obvious. For example, patients with trauma in the elbow region – blunt or penetrating – with clear ischemia and no radial pulse do not need arteriography before surgery.

If the patient has multiple injuries, shotgun injuries, or suspected proximal arterial involvement, arteriography is recommended to determine the exact site of injury. Arteriography should also be done when there are indistinct signs of ischemia and arterial injury is only suspected. Included in this indication for arteriography is the so-called proximity injury, referring to injury in patients without signs of distal ischemia but with trauma in close

proximity to a major artery. Of patients undergoing arteriography for this indication, 10–20% are reported to have arterial lesions. If the arteriogram reveals injury to the subclavian or axillary artery, endovascular treatment can proceed right away. Duplex scanning has replaced arteriography in some hospitals and is probably just as accurate in experienced hands. Intimal flaps and small areas of vascular wall thrombosis may be difficult to identify with duplex scanning under some circumstances, but such small lesions in the arm can, on the other hand, usually be treated without exploration.

Computed tomography (CT) angiography is an important modality for diagnosing proximal arterial injuries in particular. It is reported to be at least as accurate as arteriography in this area. The use of CT angiography is likely to increase in the near future because it is quicker than angiography, and most trauma centers have rapid access to good-quality CT.

Management Before Treatment

Severely Injured and Unstable Patients

Patients arriving to the emergency department with active serious bleeding after a single injury to an arm are rare. When this does occur, manual direct pressure over the wound can control the bleeding while general resuscitation measures according to Advanced Trauma Life Support principles are undertaken: oxygen, monitoring of vital signs, placement of intravenous (IV) lines, and infusion of fluids. It is important not to forget to administer analgesics (5–10mg of an opiate IV) and, when indicated, antibiotics and tetanus prophylaxis.

Multiply injured patients with signs of arm ischemia should be treated according to the hospital's general trauma management protocol, and the vascular injury is usually evaluated during the second survey. Serious ongoing bleeding has high priority, but arm ischemia should be managed after resuscitation and treatment of life-threatening injuries but before orthopedic repair in most circumstances. When the patient has stabilized, arteriography can be performed if indicated.

Less Severe Injuries

Most patients with arm injuries arrive in the emergency department in a stable condition without ongoing bleeding but with signs of hand ischemia. For these patients, careful examination of the arm including assessment of nerve function, is essential. Dislocated

fractures or luxations should be reduced under proper analgesia. After reduction, examination of vascular function should be repeated. If the radial pulse and distal perfusion return, the position should be stabilized and fixed. Repeated examinations during the following 4h are mandatory to ensure that the returned perfusion is persistent.

If the vessel injury is definite – an absent radial pulse and reduced hand perfusion – and the site of vascular injury is apparent, the patient can be transferred to the operating room without further diagnostic measures. Patients with findings indicating vascular injury at examination, and those with obvious arterial disruption but with arms so traumatized that the site of arterial injury cannot be determined, should undergo arteriography or duplex scanning. Expediency of repair is required for all locations of arterial injuries in the arm. The proposed time limits indicating a low risk for permanent tissue damage range from 4h for brachial artery injuries and up to 12h for forearm injuries. The risk limit for irreversible ischemia following forearm injuries is valid for patients with an incomplete palmar arch. The frequency of this anatomical variation is 20% in most Western populations.

Suspected injuries to the radial and ulnar artery should be treated according to the general principles discussed above. Even cases with normal perfusion in the hand but without a radial pulse should be explored and repaired if reasonably simple. When forearm arterial injury is unclear, the Allen test (Table 2) can be added to the examination procedure. A positive Allen test together with a history of trauma to an area in close proximity indicate that the radial or ulnar artery is indeed affected. The wound should then be explored and the traumatized artery inspected and mended. Patients with multiple severe injuries and high-risk patients should not be explored if perfusion to the hand is rendered sufficient. For those circumstances, repeat examinations every hour are mandatory to make sure that perfusion is adequate and stable.

Table 2. Allen test

1. Elevate the arm over the head
2. Occlude the radial and ulnar arteries at the wrist
4. Lower the arm
5. Release blood flow through the ulnar artery
6. Inspect and time the return of perfusion
7. Repeat, and release blood flow through the radial artery instead.
8. A return of perfusion >5 s is considered a positive Allen test, and the artery is suspected to be inadequate

Amputation

Some arms with vascular injuries are so extensively damaged that amputation is a treatment option. The decision of when to perform a primary amputation versus trying to repair vessels, nerves, tendons, and muscles is difficult. As a general principle, arms with multiple fractures, nerve disruption, ischemia-time longer than 6h, and extensive crush injuries involving muscle and skin will never regain function and should be amputated. Another principle is that when four out of the five components of the arm are injured – skin, bone, muscles, and vessels – but there is only minor nerve injury, an attempt to save the arm is reasonable. One must keep in mind, however, that the arm needs at least some protective sensation in order to be functional. Children have a greater chance of regaining a functional arm than adults do, and a generous attitude to surgical repair in children is recommended.

The mangled extremity severity score (MESS) is a grading system designed to aid the decision process for managing massive upper and lower extremity trauma. A score of 7 or more has been proposed as a cut-off value for indicating when amputation cannot be avoided and should be performed as the primary procedure. In some studies, a score 7 predicted an eventual amputation with 100% accuracy. The basis of the MESS scoring system is given in Table 3. As shown in Table 3.4, a crush injury is regarded as particularly unfavorable. The duration of ischemia is also a significant factor taken into account in the MESS system.

Table 3. MESS: Mangled Extremity Severity Score (BP blood pressure)

Types	Injury characteristics	Points
Low energy	Sab wounds, simple closed fractures, small-caliber gunshot wounds	1
Medium energy	Open fractures, multiple fractures, dislocations, small crush injuries	2
High energy	Shotgun blasts, high-velocity gunshot wounds	3
Massive crush	Logging, railroad accidents	4
No shock (BP normal)	BP stable at the site and at the hospital	1
Transient hypotension	BP unstable at the site but normalizes after fluid substitution	2
Prolonged hypotension	BP <90 mmHg	3
No distal ischemia	Distal pulses, no signs of ischemia	1
Mild ischemia	Absent or diminished pulses, no signs of ischemia	2 ^a
Moderate ischemia	No signals by continuous-wave Doppler, signs of distal ischemia	3 ^a
Severe ischemia	No pulse; cool, paralyzed limb; no capillary refill	4 ^a
<30 years old patient		1
>30 years old patient		2
>50 years old patient		3

^a Points are doubled if ischemia lasts longer than 6 h.

Operation

Preoperative Preparation

Hemodynamically stable patients are placed on their back with the arm abducted 90° on an arm surgery table. The forearm and hand should be in supination. Peripheral or central IV lines should not be inserted on the injured side. Any continuing bleeding is controlled manually directly over the wound. If the site of injury is the brachial artery or distal to it, a tourniquet can be used to achieve proximal control. It is then placed before draping and should be padded to avoid direct skin contact with the cuff. This minimizes the risk for skin problems during inflation. The arm is washed so the skin over the appropriate artery can be incised without difficulty. The draping should allow palpation of the radial pulse and inspection of finger pulp perfusion. One leg is also prepared in case vein harvest is needed.

The position of the arm is the same for more proximal injuries. Proximal control of high brachial and axillary artery trauma may involve exposure and skin incisions in the vicinity of the clavicle and the neck, so for proximal injuries the draping must also allow incisions at this level.

Proximal Control

For distal vessel injury, proximal control can be achieved by inflating the previously placed tourniquet to a pressure around 50 mmHg above systolic pressure. The cuff should be inflated with the arm elevated to minimize bleeding by venous congestion. After inflation, the wound is explored directly at the site of injury.

For more proximal injuries, control is achieved by exposing a normal vessel segment above the wounded area. The most common sites for proximal control in the arm are the axillary artery below the clavicle, and the brachial artery (which is what the artery is called distal to the teres major muscle) somewhere in the upper arm.

Exposure for Proximal Control of Arteries in the Arm

Axillary Artery Below the Clavicle

An 8-cm horizontal incision is made 3 cm below the clavicle (Fig. 2). The pectoralis major muscle fibers are split parallel to the skin incision. The pectoralis minor muscle is divided close to its insertion. The nerve crossing the pectoralis minor muscle can also be divided without subsequent morbidity. The axillary artery lies immediately below the fascia together with the vein inferiorly, and the lateral cord of the brachial plexus is located above the artery.

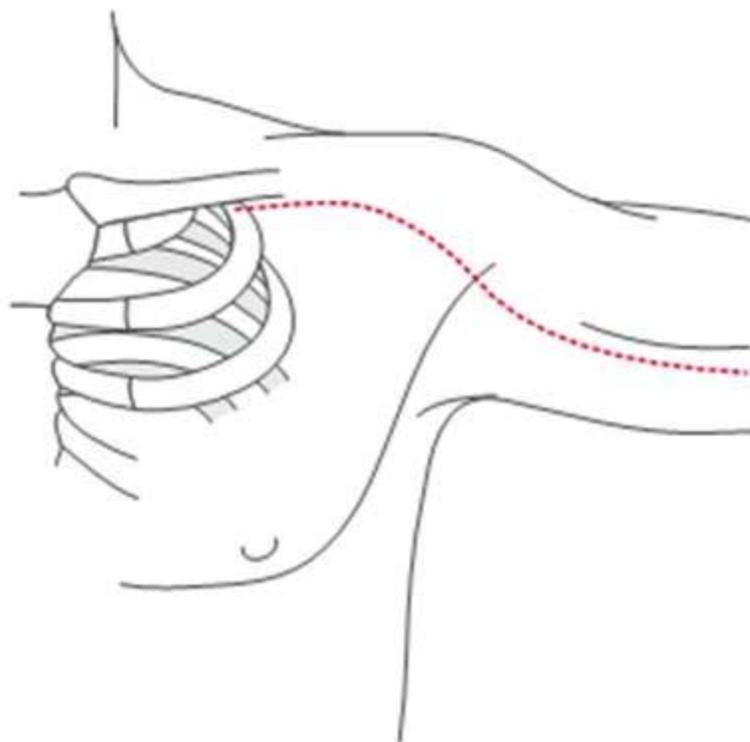

Fig. 2

Brachial Artery in the Upper Arm

The incision is made along the posterior border of the biceps muscle; a length of 6–8 cm is usually enough (Fig. 3.). The muscles are retracted medially and laterally, and the artery lies in the neurovascular bundle immediately below the muscles. The sheath is incised and the artery freed from the median nerve and the medial cutaneous nerve that surrounds it.

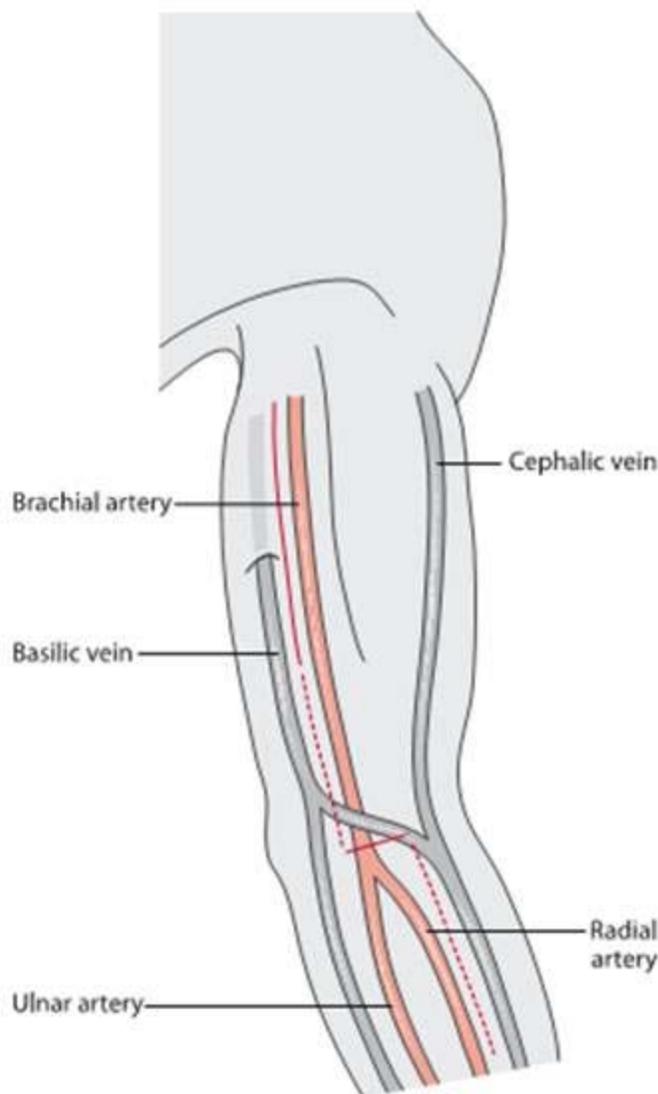

Fig. 3. Transverse incision in the elbow for exposing the brachial artery and with possible elongations (dottedlines) when access to the ulnar and radial ranches as well as to more proximal parts of the brachial artery is needed

Brachial Artery at the Elbow

The incision is placed 2 cm below the elbow crease and should continue up on the medial side along the artery. If possible, veins transversing the wound should be preserved, but they can be divided if necessary for exposure. The medial insertion of the biceps tendon is divided entirely, and the artery lies immediately beneath it. By following the wound proximally, more of the artery can be exposed (Fig. 3.). If the origins of the radial and ulnar artery need to be assessed, the wound can be elongated distally on the ulnar side of the volar aspect of the arm. The median nerve lies close to the brachial artery, and it is important to avoid injuring it.

Exploration and Repair

Distal control is achieved by exploring the wound. Sometimes this requires additional skin incisions. The most common site for vascular damage in the arm is the brachial artery at the elbow level. These injuries occurs, for example, because of supracondylar fractures in children and adults. In such cases, exposure and repair of the brachial artery through an incision in the elbow crease is appropriate. Hematomas should be evacuated to allow inspection of nerves and tendons.

For supracondylar fractures, the brachial artery, the median nerve, and the musculocutaneous nerves must sometimes be pulled out of the fracture site. Before the artery is clamped, the patient is given 50 units of heparin/kg body weight IV. Repair should also be preceded by testing inflow and backflow from the distal vascular bed by temporary tourniquet or clamp release. It is often also wise to pass a #2 Fogarty catheter distally to ensure that no clots have formed. Occasionally, inflow is questionable, and proximal obstruction must be ruled out. As a general principle, all vascular injuries in the arms should be repaired, except when revascularization may jeopardize the patient's life. Arterial ligation should be performed only when amputation is planned. Postoperative arm amputation rates are reported to be 43% if the axillary artery is ligated and 30% at the brachial artery level. Another exception is forearm injuries. When perfusion to the hand is rendered adequate – as assessed by pulse palpation and the Allen test – one of these two arteries can be ligated without morbidity. In a substantial number of patients with differing vessel anatomy, however, ligation of either the ulnar or radial artery may lead to hand amputation. If both arteries are damaged, the ulnar artery should be prioritized because it is usually responsible for the main part of the perfusion to the hand.

For most arterial injuries, vein interposition is necessary for repair. Veins are harvested from the same arm, from parts of the cephalic or basilic vein if the trauma is limited, or from the leg. The saphenous vein in the thigh is suitable for axillary and brachial artery repair, while distal ankle vein pieces can be used for interposition grafts to the radial and ulnar arteries. Before suturing the anastomoses, all damaged parts of the artery must be excised to reduce the risk of postoperative thrombosis. Rarely, primary suture with and without patching can be used to repair minor lacerations. Shunting of an arterial injury to permit osteosynthesis is rarely needed in the arm. Vascular interposition grafting can usually be done with an appropriate graft length before final orthopedic repair. Also, extremity shortening due to fractures is less of a problem in the arms (in contrast to the legs), and orthopedic treatment without osteosynthesis

is common especially in older patients. Nevertheless, for some arm injuries shunting is a practical technique that allows time for fracture fixation, thus avoiding the risks of redisplacement and repeated vessel injury. One example is injuries to the axillary or brachial artery caused by a proximal humeral fracture, where the fragment needs to be fixed in order to prevent such injuries. Another example is humeral shaft fracture, which needs to be rigidly fixed to abolish the instability that may otherwise endanger the vascular graft. Veins should also be repaired if reasonably simple. If the vein injury is caused by a single wound with limited tissue damage, concomitant veins to the distal brachial artery can be ligated. For more extensive injuries where the superficial large veins are likely to be ruined, it is wise to try to repair the deep veins. For very proximal injuries in the shoulder region, vein repair is important to avoid longterm problems with arm swelling. It is also important to cover the mended vessel segment with soft tissue to minimize the risk for infection that may involve the arteries.

Finishing the Operation

When the repaired artery or graft's function is doubtful and when the surgeon suspects distal clotting, intraoperative arteriography should be performed. After completion, all devitalized tissue should be excised and the wound cleaned. For penetrating wounds, damaged tendons and transected nerves should also be sutured. This is not worthwhile for most blunt injuries. Fasciotomy should also be considered before finishing the operation. As in the leg, long ischemia times and successful repair increase the risk of reperfusion and compartment syndrome, but the overall risk for compartment syndrome is reported to be less in the arm than in the leg. For a description of arm fasciotomy techniques, we recommend consulting orthopedic textbooks. After the wounds are dressed, a fractured arm is put into a plaster splint for stabilization.

Endovascular Treatment

In contrast to proximal arm vessel trauma, there are few instances in distal injuries when endovascular treatment is a feasible treatment option. Because the brachial artery and the forearm vessels are easy to expose with little morbidity, open repair during exploration of the wound is usually the best option. Possible exceptions to this are treatment of the late consequences of vascular trauma, such as arteriovenous fistulas and pseudoaneurysms. Especially in the shoulder region, including the axilla, primary endovascular treatment is often

the best treatment option. Another circumstance when endovascular treatment is favorable is bleeding from axillary artery branches – such as the circumflex humeral artery – due to penetrating trauma. Active bleeding from branches, but not from the main trunk, observed during arteriography is preferably treated by coiling. The bleeding branches are then selectively cannulated with a guidewire and coiled, using spring coils or injections of thrombin to occlude the bleeding artery.

Management After Treatment

Postoperative monitoring of hand perfusion and radial pulse is recommended at least every 30 min for the first 6 h. When deteriorated function of the repaired artery is suspected, duplex scanning can verify or exclude postoperative problems. Apparent occlusions should be treated by reoperation as soon as possible. Compartment syndrome in the lower arm may also evolve over time, and swelling, muscle tenderness, and rigidity must also be monitored during the initial days. For most patients, treatment with low molecular weight heparin is continued postoperatively. A common dose is 5,000 units subcutaneously twice daily.

Keeping the hand elevated as much as possible may reduce swelling of the hand and arm as well as problems with hematoma formation around the wound. Early mobilization of the fingers facilitate blood flow to the arm and should be encouraged.

VASCULAR INJURIES IN THE LEG

Vascular trauma to extremity vessels is caused by violent behavior or accidents. Because of the rise in the number of endovascular procedures, iatrogenic injuries have also become an increasing part of vascular trauma. Vascular injuries may cause life-threatening major bleeding, but distal ischemia is more common. Ischemia occurs after both blunt and penetrating trauma. The vascular injury is often one of many injuries in multiply traumatized patients that make the recognition of signs of vascular injury – which can be blurred by more apparent problems – and the diagnosis difficult. Table 9.1 lists common locations of combined orthopedic and vascular injury. Multiple injuries also bring problems regarding priority.

Table 4. Most common locations for combined orthopedic and vascular injury

Orthopedic injury	Vascular injury
Femoral shaft fracture	Superficial femoral artery
Knee dislocation	Popliteal artery
Fractured clavicle	Subclavian artery
Shoulder dislocation	Axillary artery
Supracondylar fracture of the humerus	Brachial artery
Elbow dislocation	

Data on the true incidence of vascular injuries to the legs is hard to gather. The incidence of vascular trauma varies among countries and also between rural and urban areas. It is usually higher where gunshot wounds are common. There is an equal share of blunt and penetrating injury in most studies from Europe, whereas penetrating injury is slightly more common in the United States. Approximately 75% of all vascular injuries are localized to the extremities and more than 50% to the legs. The true incidence of iatrogenic trauma is unknown.

Etiology and Pathophysiology

Penetrating Injury

Penetrating vascular injury is caused by stab and cutting injuries, gunshots, and fractures, the latter when sharp bone fragments penetrate the vascular wall. Gunshots cause major bleeding by direct artery trauma, while high-velocity bullets create a cavitation effect with massive soft tissue destruction and secondary arterial damage. In fact, after all types of penetrating trauma both bleeding and indirect blunt arterial injury with ischemia may occur. Bleeding is more often exsanguinating after sharp injury and partial vessel transection. Complete avulsion, especially when caused by blunt trauma, makes the vessel more prone to retraction, spasm, and thrombosis. This diminishes the risk for major bleeding. Iatrogenic injuries can be caused by catheterization and during surgical dissection.

Blunt Injury

Blunt vascular injuries are usually caused by motor vehicle and other accidents. The consequences are thrombosis and ischemia distal to the injured vessel. The media and the intimal layers of the vessel wall are easily separated, and subsequent dissection by the bloodstream between the layers may lead to lumen obstruction. Blunt injuries also induce thrombosis. This type of vessel injury is particularly common when the artery is hyperextended as in knee joint luxations and upper arm fractures. Contusion of the vessel may also cause bleeding in the vessel wall. Thrombosis and ischemia by this mechanism can occur several hours after the traumatic situation. Narrowing of the arterial lumen following blunt trauma is rarely caused by spasm and it can be disregarded as etiology.

Pathophysiology

The main pathophysiological issue after vascular injuries to the extremities is ischemia. The process is identical to what happens during acute leg ischemia due to embolization. Irreversible damage to the distal parts of the legs is not infrequent and the diagnosis is more difficult to determine than for other types of leg ischemia. The reason is the multiple manifestations of the trauma. It must be kept in mind that the time limit for acute leg ischemia – 4–6 h before permanent changes occur – is also valid for trauma.

A vascular injury missed during the initial examination may develop into a pseudoaneurysm or an arteriovenous fistula. A pseudoaneurysm is a hematoma with persistent blood flow within it that may enlarge over time and cause local symptoms and sometimes even rupture. When both an artery and an adjacent vein are injured simultaneously an arteriovenous fistula may develop. These can become quite large with time and even cause cardiac failure due to increased cardiac output.

Medical History

Most patients with major vascular injury present with any or several of the “hard signs” of vessel injury (Table 5) and the diagnosis is obvious. Penetrating injury patients who arrive in the emergency department without active hemorrhage are usually not in shock because the bleeding was controlled at the trauma scene. Shock in patients with penetrating injury usually means that the bleeding is ongoing. Still, information about the trauma mechanism is often needed to estimate the likelihood for vessel injury and to facilitate the management process.

Besides interviewing the patient, additional background information may be available from medical personnel and accompanying persons. The few minutes required to establish a picture of the trauma situation are usually worthwhile. For example, a history of a large amount of bright red pulsating bleeding after penetrating trauma suggests a severe arterial injury. Venous bleedings are often described as a steady flow of dark red blood. In high-impact accidents the risk for a severe vascular injury is increased.

Besides being helpful when assessing the risk for a major injury estimation of the blood loss is also important for later volume replacement. Knowledge of the exact time when the injury happened is helpful for determining the available time before irreversible damage occurs from ischemia. The duration of ischemia also influences the management priority in multitrauma patients, and the time elapsed affects the presentation of the ischemic symptoms. For example, an initial severe pain may vanish with time as a consequence of ischemic nerve damage. Even a major internal hemorrhage may be present without being clinically obvious after a very recent injury. Information about complicating diseases and medication is also helpful. For instance, betablockers may abolish the tachycardia in hypovolemia.

Table 5. Signs of vascular injury

Hard signs	Soft signs
Active hemorrhage	History of significant bleeding
Hematoma (large, pulsating, expanding)	Small hematoma
Distal ischemia ("six Ps")	Adjacent nerve injury
Bruit	Proximity of wound to vessel location
	Unexplained shock

Clinical Signs and Symptoms

The physical examination is performed after the primary and secondary surveys of a multitrauma patient and should focus on identifying major vessel injury. The examination

should be thorough, especially regarding signs of distal ischemia. It should include examination and auscultation of the injured area, palpation of pulses in both legs, and assessment of skin temperature, motor function, and sensibility. The presence of one or more of the classic hard signs of vascular injury listed in Table 5 suggests that a major vessel is damaged and that immediate repair is warranted. Findings of “soft” signs should bring the examiner’s attention to the fact that a major vessel may be injured but that the definite diagnosis requires additional work-up. As noted in Table 5, the hard sign of distal ischemia as suggested by the “six Ps” suggests vascular injury.

The principles of the vascular examination suggested for acute leg ischemia are also valid for vascular injuries, but certain details need to be emphasized. Vascular trauma in the legs usually strikes young persons, so it should be assumed that the patient had a normal vascular status before the injury. A palpable pulse does not exclude vascular injury; 25% of patients with arterial injuries that require surgical treatment have a palpable pulse initially. This is due to propagation of the pulse wave through soft thrombus. Pulses may be palpated initially in spite of an intimal flap or minor vessel wall narrowing and can later cause thrombosis and occlude the vessel. Ankle pressure measurements and calculation of the ankle brachial index (ABI) should therefore supplement palpation of pulses. If the ABI is ≤ 0.9 , arterial injuries should be suspected.

Findings in the physical examination of a patient in shock are particularly difficult to interpret. In several aspects findings of distal ischemia caused by vascular injury are similar to vasoconstriction of the skin vessels in the foot. Differences in pallor, the presence of pulses, and skin temperature between the injured and uninjured leg therefore should be interpreted as the possible presence of vascular injury. Ankle pressure measurements are also valuable during such circumstances.

It is important to remember to listen for bruits and thrills over the wounded area to reveal a possible arteriovenous fistula.

Diagnostics

Recommendations for management of suspected vascular injuries in the leg have evolved from mandatory exploration of all suspected injuries (a common practice during past wars), to routine angiography for most patients, to a more selective approach today. Regarding exploration and subsequent angiography, it was found that negative explorations and arteriograms were obtained in over 80% of the patients. The associated risk for complications

and morbidity after these invasive procedures is the rationale for a more selective approach. Rapid transportation, clinical examination, ankle pressure measurements, careful monitoring, and duplex examination leave angiography for some of the patients and urgent exploration for a few.

Angiography

Angiography is unnecessary when a vascular injury is obvious after the examination. The two most common indications for excluding vascular injury are (1) when there are no hard signs at the examination, and (2) when clinical findings are imprecise but the ABI is <0.9 .

Angiography is more often indicated after blunt trauma than penetrating. The reason for this is the more difficult clinical examination because of the more extensive soft tissue and nerve damage after blunt trauma. It may occasionally be helpful to perform angiography even when injury is evident in order to exactly locate the injured vessel. An option is to perform it intraoperatively. Contralateral puncture is important when the injury is close to the groin.

The purpose of the arteriography is to identify and locate lesions such as occlusions, narrowing, and intimal flaps. Contrast leakage outside the vessel can be visualized, and it also serves to provide a road map before surgery. It has, however, been argued that it is unnecessary to search for minimal lesions; some studies have shown that it is safe and effective to manage such lesions nonoperatively. On the other hand, angiography may be the first step in the final treatment of such small lesions by stenting. When the injury is caused by a shotgun blast, angiography should always be performed because multiple vascular injuries are common. It is then indicated regardless of the clinical signs and symptoms. The risk for complications after angiography is very low, but the risk of complications is higher when the punctured artery is small. Children therefore have a rather high rate of complications. A contributing factor is that their very vasoactive arteries are prone to temporary spasm. Overall, as described above, the risk for complications after angiography does not warrant avoiding it when indicated. Occasionally it is worthwhile to order venography. It may be indicated in patients not subjected to exploration because arterial injury was ruled out but in whom a major venous injury is suspected. As an example, 5–10% of all popliteal venous injuries are reported to occur without arterial damage.

Duplex Ultrasound

Despite the usefulness of duplex scanning in general for vascular diagnosis, it has not been universally accepted for diagnosis of vascular trauma despite the fact that it is noninvasive. It is operator dependent and vessels may be difficult to assess in multiply injured patients, legs with skeletal deformities, large hematomas, and through splints and dressings. In some hospitals with expertise in duplex assessment and round-the-clock access to skilled examiners, duplex has replaced angiography to a large extent. The indications proposed are then the same as for angiography. Duplex is also the method of choice for diagnosis of most of the late consequences of vascular injuries to the legs – arteriovenous fistulas, pseudoaneurysms, and hematomas.

Management Before Treatment

Severe Vessel Injury

Major external bleeding not adequately stopped when the patient arrives to the emergency department should immediately be controlled with digital pressure or bandages. No other measures to control bleeding are taken in the emergency department and attempts to clamp vessels are saved for the operating room.

The patient is surveyed according to the trauma principles used in the hospital. For most patients without obvious vascular injuries to the leg vessels, more careful vascular assessment takes place after the secondary survey. If the vascular injury is one of many in a multitrauma patient, general trauma principles for trauma care are applied. Treatment of the vascular problem is then initiated as soon as possible when the patient's condition allows it.

Patients with hard signs of vascular injury but without other problems should be transferred immediately to the operating room. Before transfer the following can be done:

1. Give the patient oxygen.
2. Initiate monitoring of vital signs (heart rate, blood pressure, respirations, SpO₂).
3. Place at least one large-bore intravenous (IV) line.
4. Start infusion of fluids. Dextran preceded by 20ml Promiten is advised especially if

the patient has distal ischemia.

5. Draw blood for hemoglobin and hematocrit, prothrombin time, partial thromboplastin time, complete blood count, creatinine, sodium, and potassium as well as a sample for blood type and cross-match.

6. Obtain informed consent.

7. Consider administering antibiotics and tetanus prophylaxis.

8. Consider administering analgesics (5–10 mg opiate IV).

Less Severe Injuries

ABI must be measured when vascular injury is suspected. Patients with soft signs of vascular injury and an ABI <0.9 usually need arteriography to rule out or verify vascular damage. This is performed as soon as possible. Before the patient is sent to the angiosuite other injuries need to be taken into account and the priority of management discussed. Ischemic legs should be given higher priority than, for example, skeletal and soft tissue injury, and temporary restoration of blood flow can be achieved by shunting.

Patients with an ABI >0.9 and a normal physical examination (little suspicion of vascular injury) can be monitored in the ward. Repeated examinations of the patient's clinical status are important and hourly assessment of pulses and ABI the first 4–6 h are warranted. If the ABI deteriorates to a value <0.9 or if pulses disappear, angiography should be carried out.

Angiography Findings

Operative treatment and restoration of blood flow are done as soon as possible if the angiography shows arterial occlusion in the femoral, popliteal, or at least two calf arteries in proximity to the traumatized area. It should be kept in mind that occlusion of the popliteal artery is detrimental for distal perfusion and is associated with a high risk for amputation due to a long ischemia time. Patients with popliteal occlusion should therefore be taken immediately to the operating room. Debate is ongoing whether one patent calf artery in an

injured leg is sufficient to allow nonoperative treatment. Some reports have found that as long as one of the tibial vessels is intact, there is no difference in limb loss or foot problems during follow-up between operative and nonoperative treatment. Our recommendation, however, is to try to restore perfusion if more than one of the calf arteries is obstructed. If combined with ischemic symptoms or signs of embolization, angiography findings of intimal flaps, minor narrowing of an artery, or minor pseudoaneurysm (<5 mm in diameter) should also be treated. Endovascular stenting is then a good alternative to operative treatment. Expectancy could be favorable for asymptomatic patients with normal ABI. Such occult arterial injuries appear to have an uneventful course and late occlusion is extremely rare. The occasional pseudoaneurysm that will enlarge with time appears to benefit from later repair.

Primary Amputation

In most circumstances, but not always, it is reasonable to repair injured vessels. For a few patients, however, primary amputation is a better option. This is often a difficult decision. Primary amputation is favorable for the patient if the leg is massacred or if the duration of ischemia is very long (>12 h) and appears to be irreversible in the clinical examination. Primary amputation may also be considered for certain patients: multitrauma patients, patients with severe comorbid disease, and those in whom the leg was already paralyzed at the time of injury. Extensive nerve damage, lack of soft tissue to cover the wound, and duration of ischemia >6 h support primary amputation for these patient groups.

There are scoring systems, such as the Mangled Extremity Severity Score (MESS), to aid in making the decision to amputate a leg or an arm. For example, a patient over 50 years old with persistent hypotension and a cool paralyzed distal leg after high-energy trauma should have the leg amputated according to MESS. It must be stressed, however, that repair of both venous and arterial injuries is superior for most patients.

Operation

Surgical treatment of vascular injuries in the leg usually proceeds in a particular order common for most patients. First the patient is scrubbed, anesthetized, and prepared for surgery. The next step is to achieve proximal control. Occasionally, control of the bleeding by manual compression with a gloved hand needs to be maintained throughout these first two steps. Proximal control is followed by measures to achieve distal control, often accomplished during

exploration of the wound. Finally, the vessels are repaired and the wound covered with soft tissue. When the patient has other injuries that motivate urgent treatment, or has fractures in the leg that need to be surgically repaired, this last step can be delayed while perfusion to the distal leg is maintained by a shunt temporarily bypassing the injured area.

Preoperative Preparation

The patient is placed on a surgical table that allows x-ray penetration. If not administered previously, infection prophylaxis treatment is started. The entire injured extremity is scrubbed with the foot draped in a transparent plastic bag. A very good marginal of the sterile field is essential because incisions need to be placed much more proximal than the wound to achieve proximal control. The contralateral leg should also be scrubbed and draped to allow harvest of veins for grafts. The venous system in the injured leg should be kept intact if possible. If a patient is in shock and the bleeding is difficult to control, it is recommended to delay inducing the anesthesia until just before the operation begins in order to avoid increased bleeding and an accentuated drop in systemic blood pressure due to loss of adrenergic activity.

Proximal Control

In patients with injuries proximal to the femoral vessels, control is achieved through an incision in the abdominal fossa. The common or external iliac artery can then be exposed retroperitoneally and secured. Proximal control for injuries in the thigh, proximal to the popliteal fossa, is usually obtained by exposing the common femoral artery and its branches in the groin. Popliteal vessel trauma can be controlled by exposing the distal superficial femoral artery or the proximal popliteal artery through a medial incision above the knee. Inflow control for calf vessel injuries is reached by exposing the popliteal artery below the knee.

If there is no ongoing bleeding when the artery is exposed a vessel-loop is applied. Clamping should be postponed until later. If bleeding is brisk and continuous, however, the clamp is placed right away. Clamping should be attempted even if the bleeding appears to be mainly venous in origin. Arterial clamping often diminishes such bleedings substantially.

An alternative way to achieve proximal control of distal femoral, popliteal, and calf vessels is to use a cuff. A padded cuff, the width in accordance with the leg circumference, is then wrapped around the leg well above the wounded area before scrubbing and draping. In the thigh a 20-cm wide cuff is often suitable. It is important to have at least 10 cm from the lower

edge of the cuff to the wound to allow prolongation of incisions if necessary. The cuff is inflated if bleeding starts during exploration. For distal injuries this often works well and may spare the patient one surgical wound.

Exposure of Different Vessel Segments in the Leg

Common or External Iliac Arteries, Fig. 4 A, B.

a A skin incision 5 cm above and parallel to the inguinal ligament is used. This incision allows exposure of all vascular segments from the external iliac up to the aortic bifurcation.

Fig. 4 A. Exposure of common or external iliac arteries.

b The muscles are split in the direction of the fibers. Dissection is totally retroperitoneal, with attention to the ureter crossing the vessels in this region. Be careful with the iliac vein, which is separated from the artery by only a thin tissue layer. Exposure of the proximal common iliac artery and the aortic bifurcation is facilitated by a table-fixed self-retaining retractor (i.e., Martin arm).

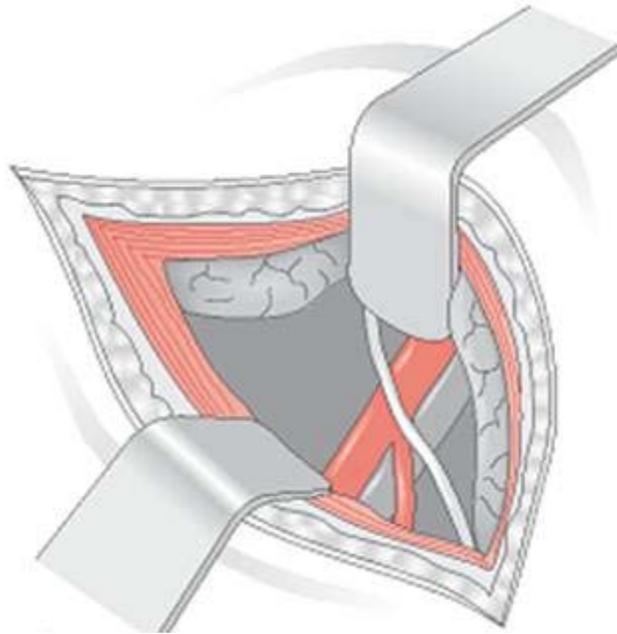

Fig. 4 B. Exposure of common or external iliac arteries.

Femoral Artery in the Groin, Fig. 5 A, B, C.

a A longitudinal skin incision starting 1–2 cm cranial to the inguinal skin fold and continued lateral to the artery is used to avoid the inguinal lymph nodes. A common mistake is to place the incision too far caudally, which usually means the dissection is taking place distal to the deep femoral.

Fig 5A. Exposure of femoral artery in the groin

b The dissection is continued sharply with the knife straight down to the fascia lateral to the lymph nodes and is then angulated 90° medially to reach the area over the artery. It should then be palpable. Lymph nodes should be avoided to minimize the risk for infection and development of seroma. The fascia is incised, and the anterior and lateral surfaces of the artery are approached.

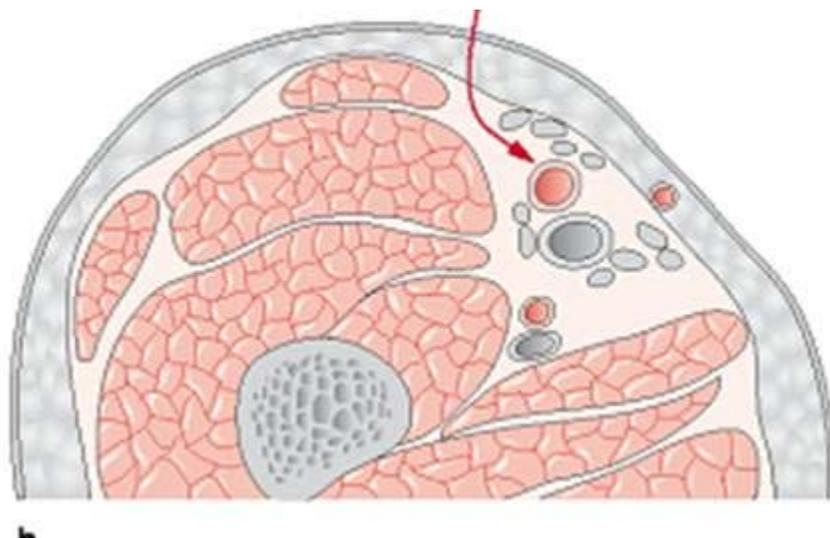

Fig. 5. Exposure of femoral artery in the groin

c At this stage the anatomy is often unclear regarding the relation of branches to the common femoral artery. Continue dissection until the bifurcation into superficial and deep femoral artery is identified. Its location varies from high up under the inguinal ligament up to 10 cm further down. At this stage, the surgeon must decide whether exposure and clamping of the common femoral are enough. This is usually the case for proximal control in trauma distally in the leg. In acute ischemia it is more common that the entire bifurcation needs to be exposed.

During the continued dissection, attention must be given to important branches that should be controlled and protected from iatrogenic injuries. These are, in particular, the circumflex iliac artery on the dorsal aspect of the common femoral artery and the deep femoral vein crossing over the anterior aspect of the deep femoral artery just after its bifurcation. To provide a safe and good exposure of the deep femoral to a level below its first bifurcation, this vein must be divided and suture-ligated. Partial division of the inguinal ligament is occasionally needed for satisfactory exposure.

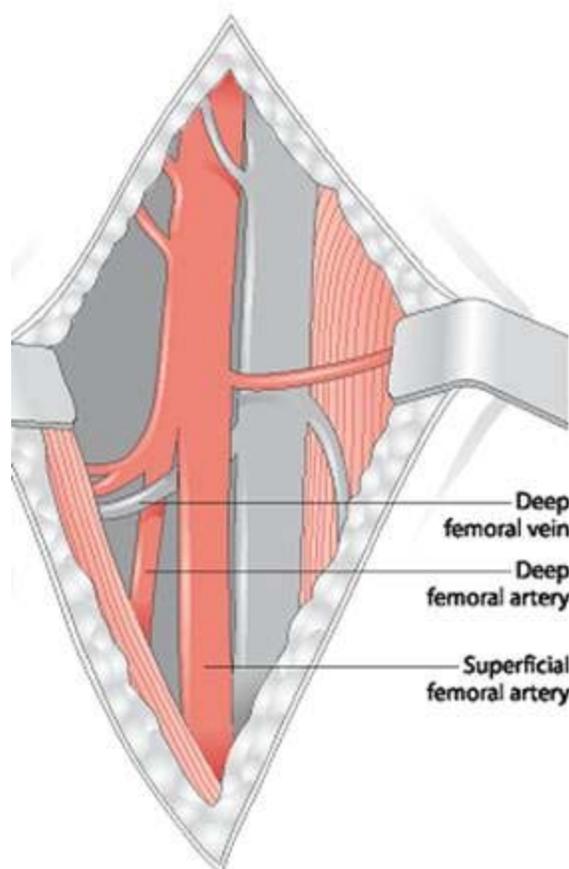

Fig. 5 C. Exposure of femoral artery in the groin

Superficial Femoral Artery, Fig. 6.

A skin incision is made along the dorsal aspect of the sartorius muscle at a midhigh level. It is important to avoid injuries to the greater saphenous vein, which usually is located in the posterior flap of the incision. The incision can be elongated as needed. After the deep fascia is opened and the sartorius muscle is retracted anteriorly, the femoral artery is found and can be mobilized. Division of the adductor tendon is sometimes required for exposure.

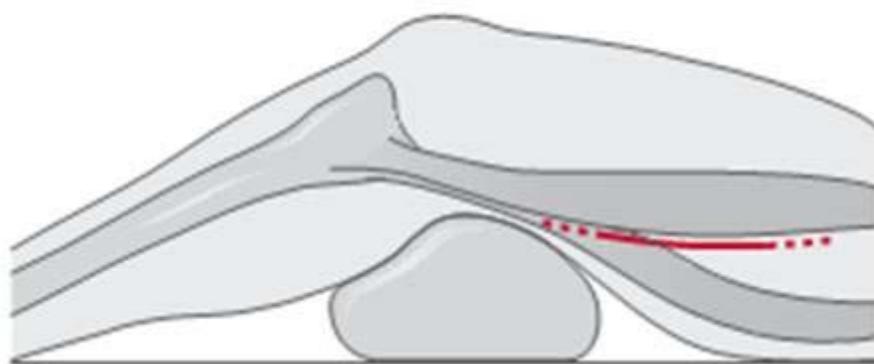

Fig. 6. Incision for exposure of the superficial femoral artery

Popliteal Artery Above the Knee, Fig. 7 A, B.

a The knee is supported on a sterile, draped pillow. The skin incision is started at the medial aspect of the femoral condyle and follows the anterior border of the sartorius muscle 10–15 cm in a proximal direction. Protect the greater saphenous vein and the saphenous nerve during dissection down to the fascia. After dividing the fascia longitudinally, continue the dissection in the groove between the sartorius and gracilis muscles, which leads to the fat in the popliteal fossa.

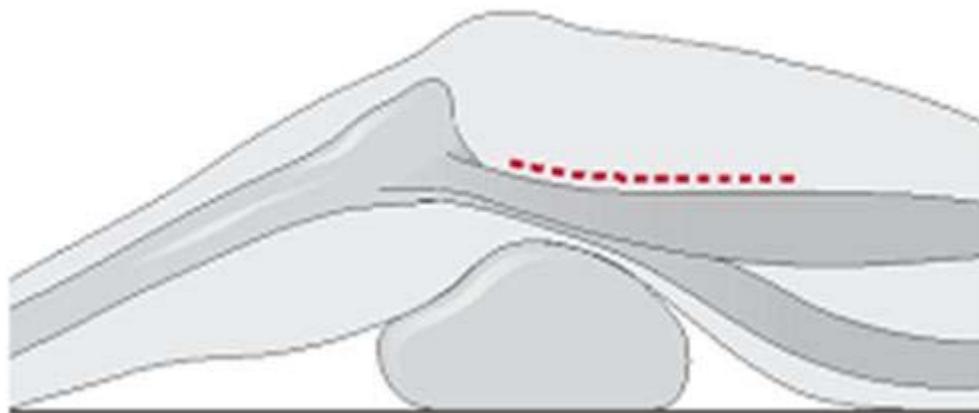

Fig. 7 . Exposure of popliteal artery above the knee

b The popliteal artery and adjacent veins and nerve are then, without further division of muscles, easily found and separated in the anterior aspect of the fossa.

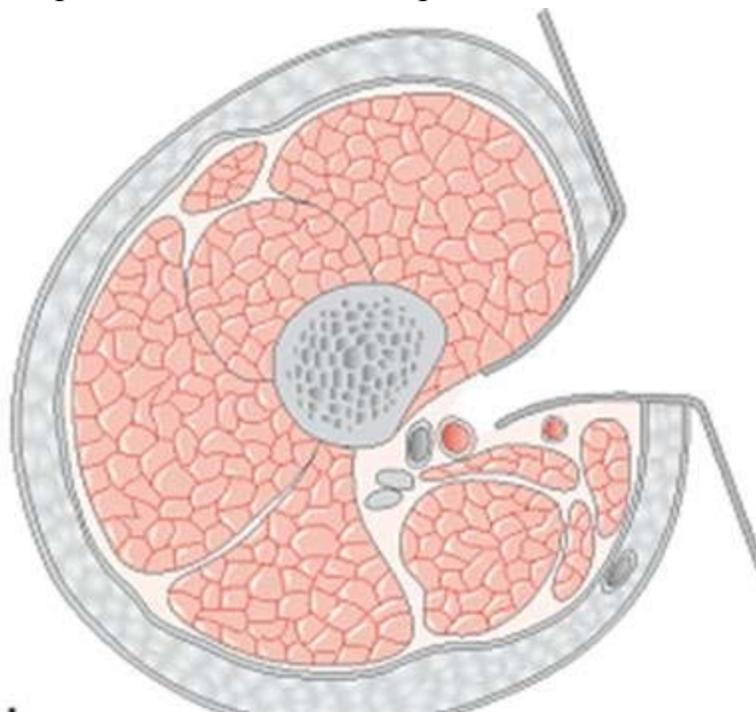

Fig. 7 B. Exposure of popliteal artery above the knee

Popliteal Artery Below the Knee, Fig. 8 A, B.

a A sterile pillow or pad is placed under the distal femur. The incision is placed 1 or 2 cm posterior to the medial border of the tibia, starting at the tibial tuberosity and extending

10–12 cm distally. Subcutaneous fat and fascia are sharply divided, with caution to the greater saphenous vein.

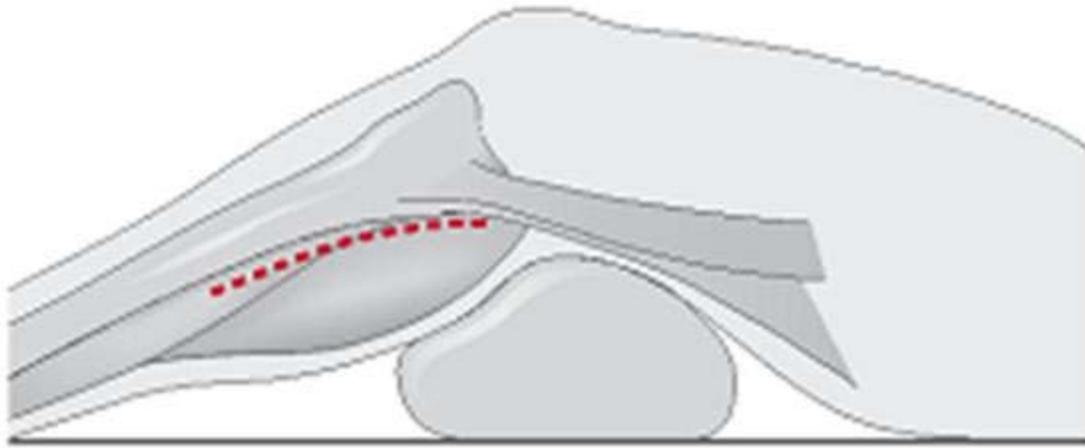

Fig. 8. A. Exposure of popliteal artery below the knee

b The popliteal fossa is reached by retracting the gastrocnemius muscle dorsally. The deep fascia is divided and the artery usually easier to identify. Occasionally, pes anserinus must be divided for adequate exposure. The popliteal artery is often located just anterior to the nerve and in close contact with the popliteal vein and crossing branches from concomitant veins. If it is necessary to expose the more distal parts of the popliteal artery, the soleus muscle has to be divided and partly separated from the posterior border of the tibia.

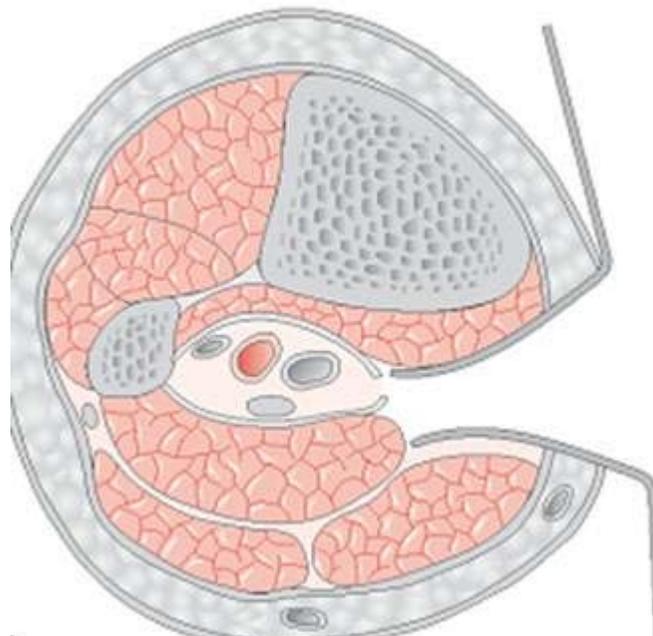

Fig. 8. B. Exposure of popliteal artery below the knee

Distal Control and Exploration

Distal control is achieved by distal elongation of the incision used to explore the site of injury. Through this incision careful dissection in intact tissue distal to the injured area usually reveals the injured artery. When it is identified and found to be not completely transected, a vessel-loop is positioned around it. If the artery is cut, a vascular clamp is applied on the stump. It is also possible to gain distal control during the exploration of the injured area, but dissection may be tricky because of hematoma, edema, and distorted anatomy. Usually the backbleeding from the distal artery is minimal and does not disturb visualization during dissection. Simultaneous venous bleeding that emerges from major veins must also be controlled. This can be done by balloon occlusion or clamps. The latter should be used with caution and closed as little as possible.

When control is obtained the wound is explored and the site of vessel injury identified. The best way is to follow the artery proximally from where the artery was exposed for distal control. Of course, any foreign materials encountered need to be removed. The injured artery should be explored in both directions until a normal arterial wall is reached. Several centimeters of free vessels are needed. Side branches are controlled using a double loop of suture with a hanging mosquito or by small vascular clamps. Thrombosed arteries usually have a hematoma in the vessel wall giving it a dark blue color. Such parts need to be cut out and the vessel edges trimmed before shunting or repair. For penetrating injuries all parts of the vascular wall that are lacerated must be excised to ensure that the intima will be enclosed in the suture line during repair. After this procedure the vessel can be shunted or repaired.

Finally, other parts of the wound are explored and all devitalized skin and muscle tissue is excised. Injured small adjacent veins should be ligated and all larger veins, such as the femoral veins and the popliteal vein, must be repaired.

Shunting

Insertion of a temporary shunt to restore distal perfusion is sensible if the vascular injury appears to require more extensive repair than a simple suture or an end-to-end anastomosis.

Shunting provides the time needed to either perform a vascular reconstruction, including harvesting of a vein graft from the uninjured leg, or to wait for help. Shunting can also be valuable when patients have other injuries that need attention or when leg fractures must be repositioned to give the appropriate vascular graft length. In patients with fractures shunting allows both repositioning and fixation without increasing the risk of ischemic damage.

A novel vascular reconstruction seldom tolerates the forces required for reposition of fractures. When perfusion is restored by a shunt the surgeon has plenty of time to carefully explore the wound and other injuries. When a shunt is used for distal perfusion while other procedures are performed, it is important to check its function at least every 30min.

The principles of vascular shunting are simple. Specially designed shunts can be used if available; examples are Pruitt–Inhara and Javid. Most have inflatable balloons in both ends for occlusion and side channels with stopcocks through which the function of the shunt can be tested (Figs. 9, 10). The side holes also enable infusion of a heparinized solution and contrast for fluoroscopy. The extra channels can be used to draw blood during the operation. It is not, however, necessary to use manufactured shunts. Any kind of sterile plastic or rubber tubing is sufficient. It is then important to use dimensions of the tube in accordance with the artery's inner diameter. The tube is cut into suitable lengths and the edges carefully trimmed with scalpel and scissors to avoid damage when inserted. The tube is positioned and secured with vessel loops that abolish the space between the artery and tube to manage bleeding. A loosely applied suture around the middle part of the shunt can be used to secure it. It is advantageous to simultaneously shunt concomitant vein injuries – at least the femoral and popliteal veins – to avoid swelling and to facilitate distal flow.

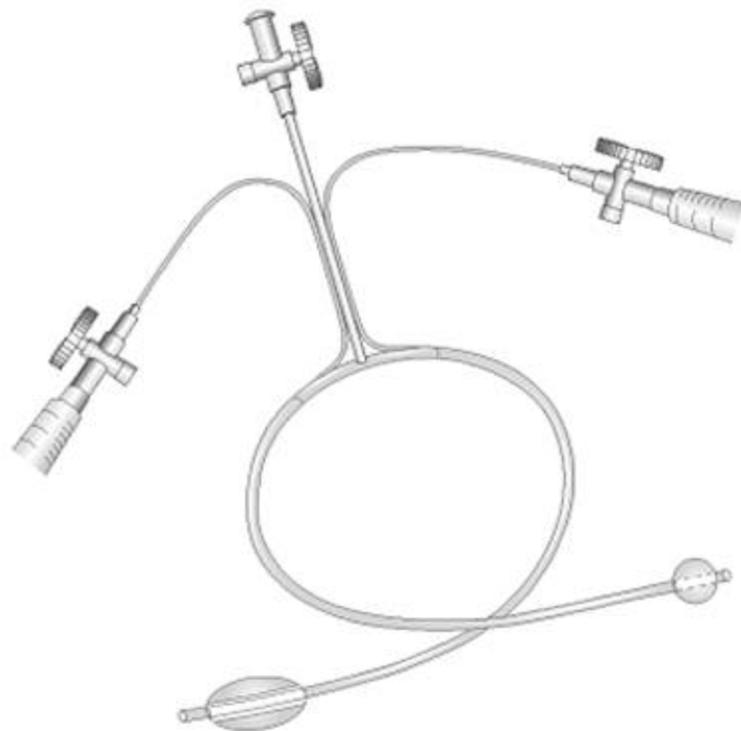

Fig. 9. A special catheter for shunting (Pruitt–Inahara shunt).

The shunt has a larger balloon in one end aimed for the proximal inflow vessel and a smaller one for placement in the outflow vessel. The occluding balloons are controlled by injecting saline through separate channels with stopcocks. The shunt can also be flushed through a third channel

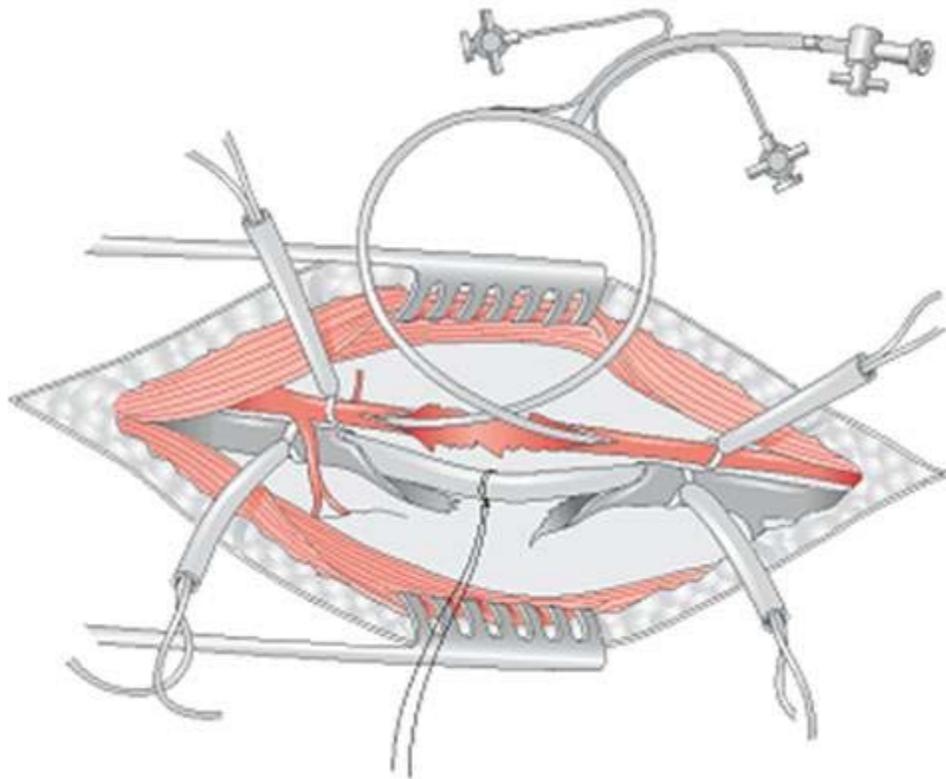

Fig. 10. Example of shunting in a severe artery and vein injury. The artery is shunted with a Pruitt–Inahara shunt and its balloons secured with vessel-loops. For shunting of the vein a piece of ordinary rubber tubing is used. It is also secured with vessel-loops and with a suture

Vessel Repair

While we advocate repairing both the artery and the vein, we do not favor reconstructing the injured vein before the artery. If both can be mended within a reasonable timeframe we recommend that the most difficult reconstruction is performed first. If, however, the artery is shunted it may be advantageous to start with the vein to achieve optimal outflow as soon as possible. Some vascular surgeons favor vein ligation as a general principle because of the potential risk for embolization from vein segments that thrombose after repair.

Arterial Injuries

In general, all injured arteries should be repaired. Sometimes, when necessary in order to save the patient's life or when interruption of an artery does not influence blood flow to the leg, the injured vessel may be ligated. The former is extremely uncommon, but the decision is

difficult when it arises. As an aid we have listed in Table 6 the amputation rates, as obtained from the literature, following ligation of vessels. Among proximal vessels, only branches from the deep femoral artery, but not the main branch, can be ligated without morbidity. Distally, we recommend repair of at least two calf arteries to be on the safe side, but it is possible to leave two interrupted, provided the remaining vessel is not the peroneal artery.

Before definitive repair the surgeon must be sure that the inflow and outflow vascular beds remain open and are free of clots. Liberal use of Fogarty catheters is therefore wise. If the backbleeding is questionable, intraoperative angiography should be performed to make sure the outflow tract is free of clots. Local heparinization, is always indicated. Systemic heparinization can be used for selected patients without other injuries considered to have a low risk for continued bleeding from the wound after debridement. If the foot's appearance or intraoperative angiography suggests microembolization, local thrombolysis can be tried.

The goal for repair is to permanently restore continuity of the artery without stenosis or tension. The type of injury determines the choice of technique. It varies from a couple of vascular sutures to reconstruction with a patch, interposition, or a bypass grafting. Lateral suture for repair of minor lesions, including patching.

A graft is usually needed, and only occasionally can an end-to-end anastomosis be performed without tension. It is always better to use an interposition graft or a bypass to avoid what is even perceived as insignificant tension because anastomotic rupture and graft necrosis may occur when leg swelling and movements pull the arterial ends further apart postoperatively. The major bleeding that can result from this may even be fatal.

Table 6. Amputation frequencies after ligation of different arteries

Vessel ligated	Amputation rate
Common iliac artery	54%
External iliac artery	47%
Common femoral artery	81%
Superficial femoral artery	55%
Popliteal artery	73%

An autologous vein is always the preferred graft material. Vein is more infection resistant than synthetic materials and is more flexible. It allows both elongation and vasodilatation to adjust variations in flow requirements. The great saphenous vein from the contralateral leg is the primary choice for a graft. It is a serious mistake to use the great saphenous vein from the traumatized leg if the deep vein is also injured or if injury is suspected. Interruption of the saphenous vein with obstructed concomitant deep veins will rapidly cause severe distal swelling of the leg and graft occlusion within days. The vein can be harvested at a level in the leg where the saphenous vein diameter fits the artery that needs to be repaired. A graft slightly larger than the artery should be obtained if possible. For common femoral artery lesions, two pieces of saphenous vein, both open longitudinally and then sutured together, might be required. An option is to use arm veins as graft material. If veins not are available expanded polytetrafluoroethylene (ePTFE) is the second choice. The main reasons not to use it are the slightly higher risks for postoperative graft occlusion and infection.

Venous injuries

Most venous injuries are exposed when the wound is explored. While vein ligation may lead to leg swelling, it rarely causes ischemia or amputation. On the other hand, the only benefit of vein ligation is rapid bleeding control and a reduced operating time. Major veins can therefore be ligated to save the life of an unstable patient. If possible, however, most veins should be repaired, especially the popliteal and the common femoral veins. Calf veins can be ligated without morbidity. In patients with combined injuries, both the vein and the artery should be repaired to enhance the function of the arterial reconstruction. Control of bleedings can be achieved by fingers or a “strawberry” or “peanut” to compress the vein proximal and distal to the injured site, or by using gentle vascular clamps. A continuous running suture, almost without traction in the suture line, is often sufficient to close a stab wound. When the vein is more extensively damaged, a patch or an interposition graft may be needed for repair. As with arteries, it is important to match the caliber of the interposition graft and the injured vein. Veins without blood are collapsed, so it is easy to underestimate their size. An autologous vein is preferred over synthetic materials.

Finishing the Operation

After the vascular reconstruction is finished the resulting improvement in distal

perfusion should be checked. This is indicated as well-perfused skin in the foot and palpable pulses. If there is any doubt about the result control angiography should be performed. Preferably, it is done from the proximal control site to enable visualization of all anastomoses. If problems are revealed the reconstruction must be redone and distal clots extracted as previously described. While vascular spasm is rare and should not be regarded as the main explanation for lack of distal blood flow, injection of 1–2 ml papaverine into the graft can also be tried.

After vascular repair all devitalized tissue and foreign material should be removed to reduce the risk of postoperative infection. Grafts and vessels should be covered with healthy tissue by loosely adapting it with interrupted absorbable sutures. For injuries with massive tissue loss it may be impossible to cover the graft. This increases the risk for postoperative anastomotic necrosis and rupture. Split or partial skin grafts or biological dressings can be used to prevent this. Occasionally it may be better to perform a bypass through healthy tissue, thus avoiding the traumatized area, to minimize graft infection and postoperative complications.

Endovascular Treatment

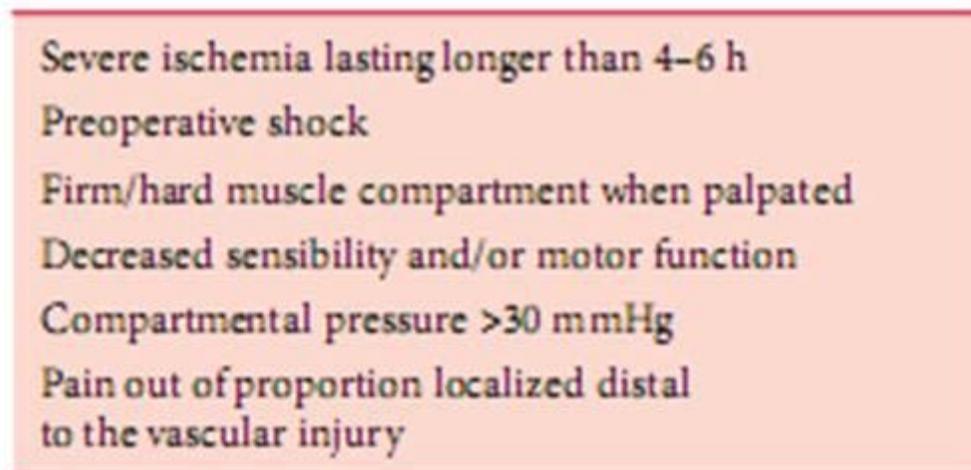

Endovascular treatment of vascular injuries to leg vessels is attractive because it provides a way to achieve proximal control, reduce ischemia time, and simplify complex procedures. There is not a lot of experience – at least not reported in the literature – with endovascular treatment. Some centers have reported successful semiselective treatment of pseudoaneurysms and arteriovenous fistulas in the groin. Small patient series have been published on embolization of bleeding branches to the deep femoral artery and stent graft control of small lacerations in the femoral arteries. We have only treated occasional patients this way so far. Endovascular treatment will probably be an option for many patients with soft signs of vascular injury, who will undergo angiography and then will be found to have a minor bleeding, a pseudoaneurysm, a fistula, or an intimal flap. The possibilities of considering endovascular repair for patients with hard signs of vascular injury to the legs will depend on logistics and the organization of a hospital's endovascular team. With around-the clock availability, patients with less severe distal ischemia may be subjected to angiography with possibilities for endovascular treatment in mind. Patients with penetrating injuries that are actively bleeding may undergo balloon occlusion of a proximal artery to accomplish control and then be transferred to the operating room for repair. In other hospitals where an endovascular team is

not available during weekends, angiography is skipped in some patients with soft signs, and they are treated with an open procedure and intraoperative angiography instead. But it is likely that endovascular treatment will be the treatment of choice for a significant proportion of patients in the near future.

Management After Treatment

As for most vascular procedures, the risk for bleeding and graft thrombosis of the reconstructed artery is higher during the first 24 h after the operation. Postoperative monitoring of limb perfusion, including inspection of foot skin and wounds and palpation of pulses, is necessary at least every 30 min for the first 6 h. If pulses are difficult to ascertain, ankle pressure should be measured. Loss of pulses or an abrupt drop in pressure indicate that reoperation may be required, even when the graft appears to be patent either clinically or on duplex scanning. As for acute leg ischemia caused by thrombosis, there is also a substantial risk for compartment syndrome. Particularly when the ischemia duration has been long, this risk is considerable, and it is important to examine calf muscles for signs of compartment syndrome. This assessment includes motor function, tenderness, and palpation of the muscle compartments in the calf. Findings that may suggest fasciotomy are listed in Table 7.

Table 7. Medical history and clinical findings suggesting that fasciotomy may be needed

Severe ischemia lasting longer than 4–6 h
Preoperative shock
Firm/hard muscle compartment when palpated
Decreased sensibility and/or motor function
Compartmental pressure >30 mmHg
Pain out of proportion localized distal to the vascular injury

For most patients administration of dextran or low molecular weight heparin is indicated to avoid postoperative thrombosis. This is especially important for patients with both venous and arterial reconstruction. Patients who have been subjected to venous ligation need extra

attention and measures against limb swelling. Antibiotic treatment started preoperatively or intraoperatively is usually continued after the operation. We use a combination of benzylpenicillin and isoxazolyl penicillin to cover streptococci, clostridia, and staphylococci.

Fasciotomy

When the compartment pressure is clearly increased or when there is a risk of developing increased pressure, fasciotomy of muscular compartments distal to a vascular injury should be performed in association with the vascular repair. Factors suggesting an increased pressure are listed in Table 7.

Fasciotomy of the Calf Compartments (Two Incisions)

Medial Incision

A 15–20-cm-long skin incision, starting slightly below the midpoint of the calf and downwards parallel to and 2–3 cm dorsally of the medial border of the tibia, is used to decompress the deep and superficial posterior muscle compartments (Fig. 11). It is important to avoid injury to the great saphenous vein. Sharp division of skin and subcutaneous fat reaches the fascia. The skin and subcutaneous fat is mobilized en bloc anteriorly and posteriorly to expose it enough to provide access to the compartments. The fascia is then opened in a proximal direction and distally down toward the malleolus under the soleus muscle. At this level, the soleus muscle has no attachments to the tibia, and the deep posterior compartment is more superficial and easier to access. Through the same skin incision, the fascia of the superficial posterior muscle compartment is cleaved 2–3 cm dorsally and parallel to the former. A long straight pair of scissors with blunt points is used to cut the fascia using a distinct continuous movement in the distal direction, down to a level of 5 cm above the malleoli and proximally along the entire fascia.

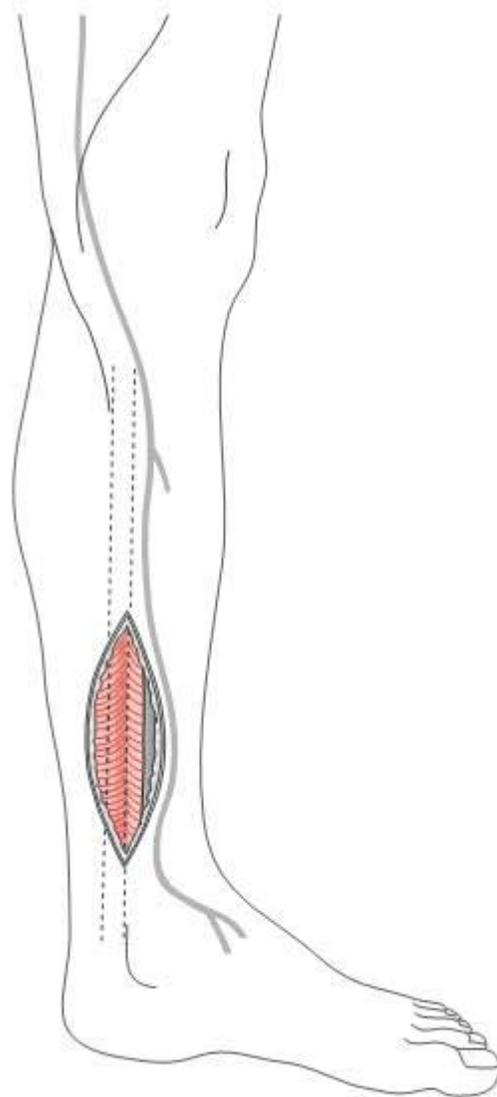

Fig. 11. Incision and exposure for fasciotomy of posterior compartments. The posteriodottedline indicates fasciotomy incision for the superficial compartment and the anteriordottedline for the deep compartment

Lateral Incision

The skin incision for fasciotomy of the lateral and anterior muscle compartments is oriented anterior to and in parallel with the fibula. The dorsal position of the lateral compartment, however, often requires more extensive mobilization of the subcutaneous fat to reach it. The superficial peroneal nerve is located anteriorly under the fascia and exits the compartment through the anterior aspect of the fascia distally in the calf. To preserve this nerve, direct the scissors dorsally when making the fasciotomy in both directions. (See Fig.

11.).

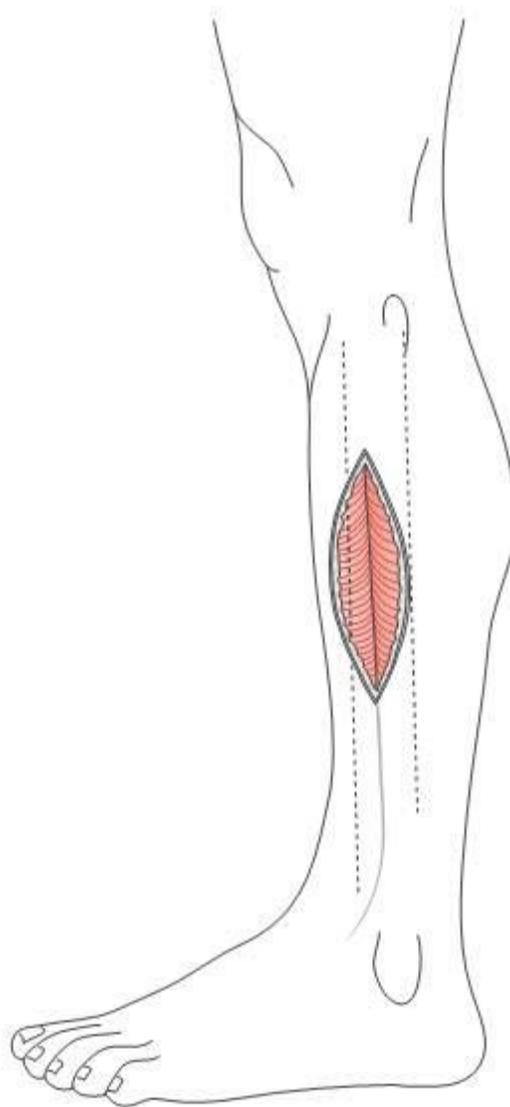

Fig. 11. Incision for fasciotomy of anterior and lateral compartments. Through the demonstrated skin incision, long incisions are made along the dottedlines in the fascia. Caution must be taken with the peroneal nerve

Unless the swelling is very extensive, 2-0 prolene intradermal suture is loosely placed to enable wound closure later (Fig. 12). It is important to leave long suture ends at both sides to allow wound edge separation the first postoperative days. The skin incisions are left open with moist dressings.

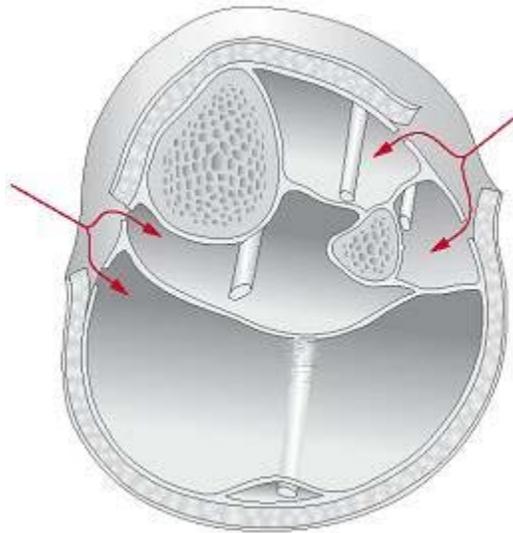

Fig. 12. Cross-section demonstrating the principles for decompression of all four muscle compartments in the calf through a medial and a lateral incision. The location of major nerve bundles in the different compartments is indicated

TRAUMATIC INJURY OF THE VENA CAVA AND ITS MAJOR BRANCHES

Trauma mechanisms

In general, the superior thoracic, intrapericardial and retrohepatic segments of the caval vein may sustain either a penetrating or a closed trauma. The VC is usually involved in single penetrating injuries.

Closed trauma

Closed injuries usually result from a severe deceleration trauma in the horizontal direction such as in traffic accidents, or in the vertical direction, like in a fall from high altitude. The resulting shear forces cause a partial or total avulsion of the venous segment, as can be observed at the atriocaval or hepatocaval junctions, or at the level of the azygos, renal, or superior mesenteric veins.

The common and internal iliac veins are damaged where they pass bony structures, especially after pelvic fractures.

In the literature, 10 cases of post-traumatic thrombosis of the IVC were found in 1999, occurring 3 days to 3 years after a high-energetic trauma. This thrombosis could have been secondary to organization of an initially localized thrombus, which allowed spontaneous hemostasis after an injury to the vessel wall.

As an anecdote, a laceration of the IVC was reported following a nonpenetrating trauma caused by the high-pressure water jet of an industrial cleaner.

Penetrating trauma

The most frequent penetrating traumas are those from gunshots rather than stabbing weapons. The statistical preponderance of dexterity among the attackers explains why the caval vein, in its right lateral position, is spared most of the time during frontal attacks on the left part of the body.

All kinds of trauma, varying between a localized puncture and injuries with substantial tissue loss, can occur. Bullet injuries are the most destructive. Except for the trauma to the caval vein, they are often responsible for other serious lesions to neighboring structures that induce a risk of sepsis, which in part influences the prognosis.

Iatrogenic trauma

This may concern vessel wall perforations due to the introduction of an endoluminal catheter or caval filter, of which the prognosis is usually good when untreated, or injuries occurring during surgery. Trauma occurring during thoracoscopy or laparoscopy may either pass unnoticed or be revealed secondarily, or may be diagnosed directly because of excessive blood loss during the procedure.

As this type of trauma is becoming more and more frequent due to the increasing use of these techniques, it forms the topic of another chapter of this book. Finally, direct iatrogenic damage to the left innominate vein or the intrapericardial caval vein can complicate certain cardiac re-interventions.

General intervention principles

Generally speaking, no additional investigations should interfere with the initial reanimation of a patient with an injured abdomen or thorax. Not until the condition has been

stabilized can a transthoracic cardiac or abdominal ultrasound exam be performed. When the clinical suspicion of a major vascular trauma has risen, a surgical exploration is justified.

In several North American series, patients in whom reanimation remained insufficient underwent an urgent clamping of the thoracic descending aorta through a left anterolateral thoracotomy.

Although meant to restore arterial pressure in these dying patients, this heroic maneuver yielded disappointing results. In 2001 Carr et al. Reported only 14 survivors out of 151 cases in the literature treated in this manner. In another series reporting on the outcome of 302 abdominal vascular injuries, thoracotomy was performed in 131 cases (43%), of which 43 times (14%) were in the shockroom and 88 times (29%) in the operating room.

The survival rates in these two groups were only 2% and 10%, respectively. In another recent series on 136 IVC injuries, one single patient survived out of 25 who underwent a thoracotomy for clamping. These results can be explained by the fact that the most severely injured patients would obviously have died already on the site of the accident, were it not for the modern means of transport and prehospital reanimation.

Local consequences of caval vein trauma

Half of the patients who suffered from a caval vein trauma, and particularly those with an arterial lesion, present with a severe hemorrhagic shock. As opposed to the arteries, the veins show a poor vasoconstrictor response and cannot generate an effective hemostasis through their own physiologic properties.

Because of the absence of valves, IVC injuries are not only characterized by bleeding from the iliac, but also by reflux from the atrial side. These veins, however, do have some features that can lead to a spontaneous hemostasis, at least temporarily.

The circulation, including the caval veins, is maintained at low pressure. In case of an IVC injury, the neighboring tissues can cause an effective plugging that limits the hemorrhage and sometimes leads to thrombus formation and healing of the vessel wall. The hemorrhage may thus be contained by the retroperitoneum, the pancreas, the duodenum or the posterior side of the liver. This phenomenon is particularly seen in simple lesions caused by stabbing weapons or low-velocity shot wounds, but is exceptional in case of a perforating trauma of the IVC or damage secondary to highvelocity fire weapons.

Common principles of major venous injuries

Patients who make it to the operating room should be treated by a surgical team of sufficient number.

In order to respond to a possible decompensation during anesthetic induction or surgical incision, they are usually anesthetized after preparation of the skin and operation field. In most cases the patient is positioned in the dorsal decubitus position, and the operation field runs down from the thoracic and abdominal areas to the knees. The unanimously acknowledged surgical access in case of an abdominal venous injury is a median laparotomy from xyphoid to pubic area, to which a median sternotomy is added. After the intestines are moved aside, the peritoneal cavity is emptied of a variable amount of blood by means of aspiration into a reservoir. A nonpulsating hematoma of black blood directly identifies a venous injury. Continuous aspiration of it carries the risk of exsanguination and should be prohibited. Preferably, gauzes should be packed into all abdominal quadrants, as it is difficult to localize the origin of the venous bleeding, which expands like a flat surface rather than a jet.

This hemostasis enables to optimize the hemodynamic situation by correcting the volume. A temporary clamping of the infrarenal aorta only, performed without difficulty and visibly, or even simple compression, can help to reach a stable situation.

In contrast with arterial injury, for which clamping of the inflow to obtain adequate hemostasis usually suffices, hemostasis of a venous injury requires checking of both the inflow and the outflow tract. Use of conventional clamps is dissuaded, especially when they have to be applied half blindly. Moreover, the posterior side of the IVC should be checked even more carefully to avoid additional damage.

Whenever possible, hemostasis should be achieved through direct digital compression, fixed gauzes, covered atraumatic clamps placed under visual control or by using tourniquets. Most of the traumatic lesions of the caval vein and its branches may then be treated by means of direct closure or simple ligation in certain localizations. The use of prosthetic material in the form of patches or tubular grafts is rarely necessary. Autologous venous jugular or saphenous grafts, sometimes composed and organized in order to obtain sufficient material for the reconstruction (helical graft), are preferred.

TRAUMA OF THE IVC

The IVC is more frequently subjected to trauma than the SVC. The abdominal vascular structure are mostly injured, mainly through a penetrating trauma, The problems of each

segment are described separately.

Infrarenal IVC. The infrarenal IVC is involved in 25% to 50% of the injuries to the IVC. Its exposure via a right mediovisceral approach is preferred over a median retroperitoneal approach, which offers the right access to the abdominal aorta and the left renal vein but less to the IVC.

The coloparietal exposure is pursued while retaining the duodenal area and the head and body of the pancreas to the left. This allows exposure of the right kidney and its ureter. After rotation of the viscera, the IVC can be exposed nicely from the junction of the iliac veins to its juxtahepatic segment.

A serious hemorrhage occurring during exposure of the IVC should be compressed by an assistant to allow the surgeon to continue the exposure. Subsequently, various procedures can be chosen for the hemostasis and reconstruction. The simplest one is to apply gauze over the lesion. However, maintaining sufficient compression during the whole duration of the venous repair is difficult. Total clamping of the IVC at a distance from the lesion by means of conventional clamps or tourniquets is risky due to the vulnerability of the vessel wall and the possibility of permanent reflux supplied by the collateral circulation from the azygos and lumbar veins.

A smaller vessel wall trauma can be treated by means of bipolar endoluminal clamping using occlusive balloon catheters (Fogarty), or urinary catheters (Foley). Lesions of the anterior or lateral sides of the IVC can best be handled using a large Satinsky clamp, which has the advantage that it partially clamps the lumen and thereby does not induce venous hypertension. Direct closure is the technique of choice to repair lesions of the infrarenal IVC. In urgent cases, a quick closure using thicker stitches (3/0 or 4/0) is preferable to trying to do a more esthetical but more time-consuming reconstruction using thinner stitches. This is underlined by the finding that there is no relation between the outcome of the reconstruction and the degree of residual stenosis. Rarely, a secondary enlargement of the sutured area is required. Lesions of the posterior side can be closed, either via direct exposure by rotating the IVC after resection of one or more lumbar veins, or via a transcaval approach after having enlarged the entry opening in the anterior side, which is to be repaired afterward. In case of major destruction of the vessel wall, particularly in combination with shock and other vascular lesions, ligation of the infrarenal IVC or ilio caval junction together with ligation of all lumbar veins is generally advocated.

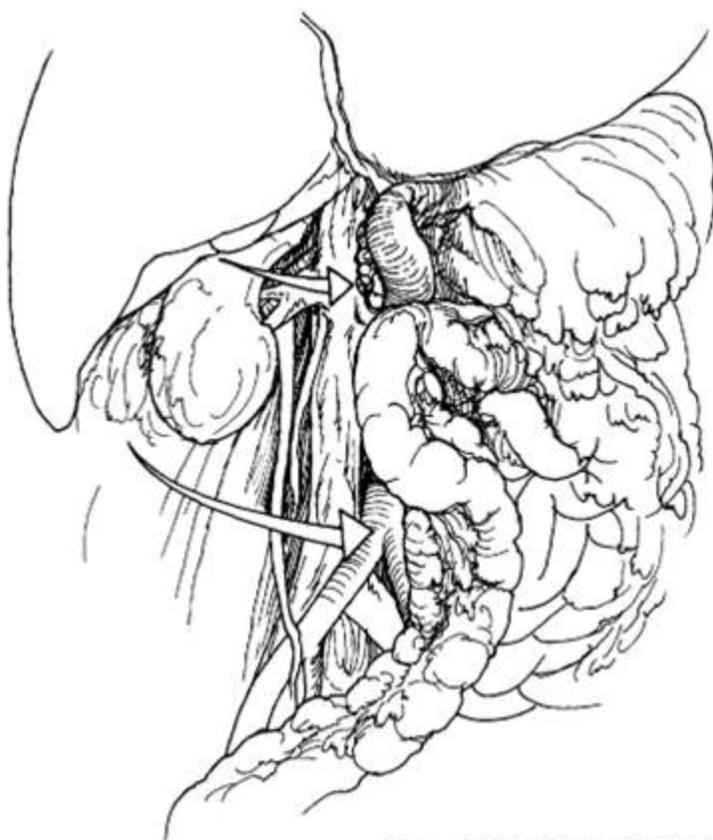

FIG. 1 Approach of the IVC, from its origin to the subhepatic segment, by right mediovisceral rotation after mobilizing the right colon, duodenum, and pancreas.

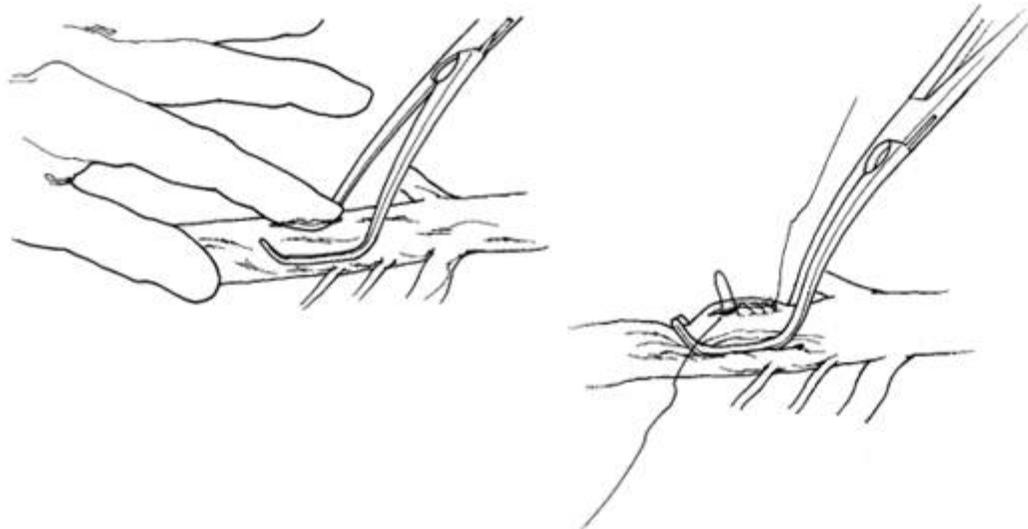

FIG. 2 Lateral clamping of the vena cava by means of a Satinsky clamp after digital control of the bleeding.

FIG. 3 Exposure and closure of a lesion in the posterior side of the IVC after transection of lumbar veins and axial rotation.

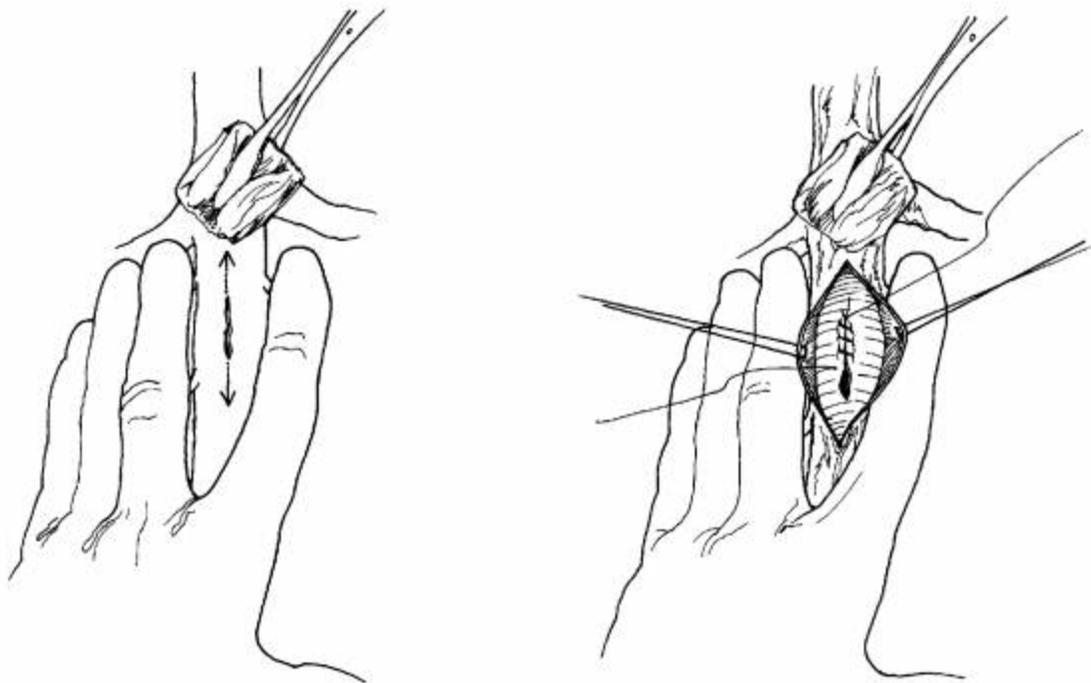

FIG. 4 Closure of a perforating lesion of the IVC. The posterior wall is sutured first via the interior of the vein after having enlarged the lesion in the front. This is closed secondarily.

Juxtarenal and juxtahepatic IVC.

The juxtarenal IVC extends two centimeters above and below the junction with the renal veins. It runs upward through a short juxtahepatic IVC, accessible via the lower border of the liver. Involvement of these segments comprises 20% to 50% of the traumatic lesions of the IVC.

Access to the Juxtarenal segment is obtained by a right mediovisceral rotation (see above). Exposure of the posterior side by means of an axial rotation requires either a right retrorenal release, mobilizing the kidney to the median line, or a complete resection between two clamps of the right renal vein, which is to be reconstructed after repositioning the IVC. The juxtahepatic segment can be approached similarly, by means of a complete right mediovisceral rotation, or more selectively by mobilizing only the duodenum and pancreas. The narrow relation between the anterior side of the IVC and the posterior side of the portal vein should be kept in mind, to avoid any damage to the latter during the dissection.

The clamping techniques do not differ much from those used for the infrarenal segment. To obtain a dry operation field at the Juxtarenal level requires the simultaneous clamping of both renal veins, sometimes including the renal arteries.

Control over the inflow and outflow of the Juxtarenal segment usually does not cause any problems. However, the outflow of the juxtahepatic IVC may be difficult because it is a short segment. Exerting anteroposterior pressure on the liver and thereby compressing the end of the juxtahepatic JVC leads to the same result. Reflux from the suprarenal vein, if any, is usually minimal. The reconstruction options for the Juxtarenal and juxtahepatic segments of the IVC can be superposed on those for the infrarenal segment in case of simple lesions. They basically consist of direct closure. Although a stenosis with a 75% caliber reduction due to this suture may be acceptable, we find it important to preserve a residual lumen of at least 30% of the initial diameter. Correction of remaining stenoses regarded excessive is the only indication for enlargement procedures by means of a venous patch rather than prosthetic material. Complete replacement of this caval segment using a venous or prosthetic graft is exceptional and restricted to cases with extensive vessel wall damage in patients whose hemodynamic condition and hemostasis allow for a complex reconstruction.

INJURIES OF THE MAJOR BRANCHES

Iliac veins.

Apart from the osseous trauma to the pelvis, iatrogenic lesions from laparoscopic procedures or maneuvers to obtain control at the common iliac artery are the most common causes of this type of injury. Access to the ilio caval junction and the distal ends of the iliac veins becomes difficult due to the bleeding that quickly fills the pelvic cavity. The best route is obtained via mobilization of the right colon, retaining it to the left of the aorta and the right common iliac artery, transected between two clamps. The ureter is the only critical structure in this region. Hemostasis is obtained by compressing the IVC with gauzes against the spine and the common iliac veins against the promontory. Hemostasis of iliac vein injuries extending into the internal iliac veins is more difficult, because of their rich collateral circulation. Direct closure is standard. A too extensive venous damage should be treated with ligation of an iliac vein or ilio caval junction. The large number of side branches between the iliac veins and the reno-azygolumbar network explains why these ligations are usually well tolerated.

Renal veins.

Injuries to the renal veins account for 8% to 12% of abdominal vascular injuries. They occur in 6% to 13% of the IVC injuries. These veins are injured by penetrating as well as by closed traumas. Iatrogenic trauma of the left retro-aortic renal vein during abdominal aortic surgery, should be avoided by careful analysis of the pre-operative computed tomography (CT) scan. Surgical exploration of retroperitoneal peri-renal hematomas is not justified in the case of a closed trauma, until an intravenous pyelography, a renal angiogram or a CT scan in a stable patient have shown a normal renal excretion.

In contrast, surgical exploration of peri-renal penetrating injuries is standard.

The right renal vein is accessed by means of mobilization of the duodenum and colon. The left renal vein is approached via a median longitudinal incision of the retroperitoneum. To reduce the bleeding it may be useful to control and clamp the renal arteries. A lateral closure, performed under digital control, either after clamping the injured vein or after lateral clamping of the IVC at its ostium, can most often be realized. If ligation of the right renal vein is necessary, one should choose between a nephrectomy and a renal autotransplantation if the hemodynamics allow for it. Ligation of the left renal vein is well tolerated as long as the capsular and genital veins are spared.

Azygos vein.

The azygos vein can be injured through penetrating and closed traumas. A massive hemothorax is common and indicates an approach via a right thoracotomy. The bleeding can be enhanced while spreading the ribs. There is a considerable risk of air embolization, which is why one should opt for an initial compression maneuver rather than excessive aspiration of the operation field. Final treatment consists of ligation of the azygos vein with lateral closure of the SVC when it is controlled by a Satinsky clamp.

Venous brachiocephalic trunk.

The right and left venous brachiocephalic trunks join to form the SVC. A lesion at this level may extend into the SVC.

In practice, the left trunk is the most affected because of its length and its tract, which crosses the median line and is exposed particularly during sternotomies for cardiac procedures. Ligation is well tolerated without any sequelae.

Postoperative measures

Whether the lesion of the IVC is repaired, ligated or simply compressed, certain measures must be taken to prevent thrombo-embolic complications resulting from stasis of blood in the lower part of the body. These comprise elevation of the legs, elastic compression and antithrombotic drugs. There is no consensus on the anticoagulation regimen.

Late sequelae, such as deep venous insufficiency, are rare regardless of the treatment chosen.

Follow-up and prognostic factors

In nearly 50% of cases, patients suffering from a traumatic lesion of the IVC die before any treatment is given. The results of 20 series in the literature, comprising 2032 operated patients, are presented in the Table, which shows that the mortality rate for all the different locations is 44% on average, ranging from 21% to 75%. No improvement is clear with time, despite a substantial progression in treatment options. Nevertheless it is plausible that the

improvement of collection and transport of the wounded has led to the operation of more and more diseased patients.

Death occurs mostly within 24 hours. In more than 90% of the cases this is due to massive bleeding, mainly during attempts to explore and repair the damage. During the early follow-up period, the bleeding induces an irreversible disseminated intravascular coagulopathy. Multi-organ failure or a sepsis, often related to intestinal lesions, are the other major causes of death after this period. The presence of shock on arrival, the existence of concomitant lesions, especially of the aorta, the closed character of the trauma, absent spontaneous hemostasis of the lesion and the retrohepatic or juxtadiaphragmatic localization are significantly associated with a poor outcome

Methodical instructions for students V years

(Vascular Surgery)

Lesson № 9 (Practical - 6 hours).

TOPIC: Arterial thrombosis and embolism.

Topics: 1. Arterial thrombosis

2. Arterial embolism.

3. Surgical treatment of arterial thrombosis and embolism

Purpose: To be able to diagnose, to know the clinic of acute vascular insufficiency of the lower extremities, depending on the causes, clinical features of disease, and to justify the conservative and surgical treatment

Professional oriented students:

Statistics show an increase in acute arterial embolism and thrombosis - severe complications, which will meet the doctors of all specialties. However, the problem of care for patients with this disease is still far from solved, as evidenced by the high mortality rate - from 20 to 35%, and the high frequency of limb amputation at the gangrene - almost 20% of patients.

Injuries are an important social and medical problem. In recent years, increased the number of serious injuries and connected, which often lead to severe bleeding and death

Methodology for practical work

The practical part of the session 9.00 - 12.00

Algorithm for communication of students with patients with any pathology, which is seen on the subject (communication skills):

1. Greet and identify himself.
2. The face should be welcoming smile - this allows you to establish a trust relationship with the patient.
3. A patient in a pleasant form should explain the purpose of the visit, the subject and the duration of the conversation and get his consent.
4. If a patient only comes to the hospital to conduct correctly, and quiet conversation with his relatives, which together with the doctor to inform them about the previous diagnosis, hospitalization, for some surveys, which are scheduled to perform in the future.
5. Before the physical examination survey methods to explain what the patient survey will be carried out, indicate some discomfort and discomfort that may feel the patient at the time of the survey, noting bound by the survey in the diagnosis of this disease and to obtain his consent.
6. If you need transportation to the place of examination (visual room, X-ray, ultrasound study) to explain its need for the patient.
7. Prepare for the survey (for data pathologies meant inspection, palpation limb aortoarteriography, ultrasound vascular feet, Doppler) - wash your hands with warm water, put on signets, prepare tools for the performance of other diagnostic manipulation.
8. To hold something or other planned medical examination or manipulation.
9. Together with the attending physician in the correct and easy to understand format patient to explain the results of either survey.
10. Involve family and patient to talk in simple terms to explain to them the results of the survey data and in the presence of previous surveys to compare their results, be sure to ascertaining whether they understand your explanations.
11. Required only in the presence of the attending physician to substantiate the feasibility of surgical intervention for the treatment of this pathology in charge of the patient.

12. Following surgical treatment only in the presence of the attending physician and with his consent should communicate the results of surgical intervention the patient and his relatives as well as the possibility of this or early or late postoperative complications.

13. Under the conditions of examination of patients in the postoperative period should be explained to the patient as true to perform hygiene procedures and the like.

14. In polite to get consent from the patient to participate in the ligation.

15. Together with your doctor to explain to the patient, and when the needs and the immediate family, those or other actions regarding manipulations that have been implemented or planned to run in the future as well as the tactics of the subsequent treatment.

16. Finish the conversation should always be the wish of the patient the most rapid recovery.

Work 1

1. Collection of complaints, history, examination of the patient.
2. Identification of clinical symptoms and instrumental.
3. Grouping symptoms syndromes.
4. Determination of the leading syndrome.
5. Interpretation of laboratory - instrumental data
6. Rationale preliminary diagnosis
7. Differential diagnosis.
8. Formulation of clinical diagnosis.
9. Appointment of differentiated treatment programs according to the clinical protocol

Work 2. Browsing the Internet, reading room with cathedral library topical literature.

Program self-students

1. Anatomical functional characteristics of arteries and veins of the lower extremities.

2. The etiology, pathogenesis and classification of acute ischemia of lower extremities.
3. Factors convolution and protivosvertochnoy systems.
4. The mechanism of thrombosis

Break - 12.00-12.30

Seminar discussion of theoretical issues - 12.30-14.00

Theme № 1. Arterial thrombosis

1. The causes of arterial thrombosis.
2. Clinical characteristics of arterial thrombosis.
3. Classification of arterial thrombosis.
4. Differential diagnosis of acute thrombosis of major arteries.
7. Indications for conservative treatment, drugs that are used.
8. Anticoagulants, phybrinolytic, thrombolytic drugs.
9. Control methods for convolution system, their characteristics.

Theme № 2 Arterial embolism

1. Causes of arterial embolism.
2. Clinical characteristics of arterial embolism.
3. Classification of arterial embolism
4. Differential diagnosis of arterial embolism
7. Indications for conservative treatment, drugs that are used.
8. Anticoagulants, fibrinolytic, thrombolytic drugs.
9. Control methods for the convolution system, their characteristics

Theme № 3 Surgical treatment of arterial thrombosis and embolism

1. Indications for surgical treatment of arterial thrombosis
2. Indications for surgical treatment of arterial embolism
3. Contraindications to surgical treatment of arterial thrombosis
4. Contraindications to surgical treatment of arterial embolism
5. Access to the main arteries

Break - 14.00-14.15

Hour self-study students - 14.15-15.00

- Tutorial test licensing examinations «Step 2»;
- Assessment of students who have not passed on the eve of the test control system «Moodle»;
- Letting students practical skills in the corresponding entry in matrikulyar book.

Sample test items and situational problems.

1. The patient admitted to hospital with a diagnosis: embolism the left popliteal artery . What is the most probable cause of embolism?
2. The patient admitted to hospital with suspected embolism the left popliteal artery. What is the symptom will testify in favor of embolism?
3. What phase hemocoagulation inhibits heparin:
 - A. Only the formation of thrombin
 - B. No right answer
 - C. Only the formation of fibrin

D. Only the formation of thromboplastin

E. It operates on the phase of thrombotic

4. Indirect anticoagulants include:

A. Preparation of 4-oksikumarina

B. Preparations of alkaloids

C. Fibrinolytic drugs

D. Pentoksiphylin

E. Thrombolytic drugs

5. The absolute contraindication of anticoagulants include:

A. Bleeding of any location, hemorrhagic diathesis

B. Aplastic anemia

C. Respiratory failure

D. Cardiovascular insufficiency

E. Lack of cerebral circulation

The student should be able to:

1. Septic endocarditis

2. Apply trombolitichiskie drugs and anticoagulants.

3. Appoint conservative therapy for acute lower limb ischemia.

4. Determine the ripple in the typical spots on the major arteries of the lower extremities.

5. Rate dopplerometry.

6. Apply methods to temporarily stop bleeding.

7. Appoint conservative therapy in acute blood loss.

The answers to tests and situational tasks:

1. Septic endocarditis
2. Severe pain in the limbs
3. A.
4. A.
5. A.

Methodical instructions for lesson № 8

THEME: "Obliterating diseases of arteries of lower extremities.

Intestinal angina.

Practical - 6 hours

Topics: 1. Obliterating atherosclerosis of lower extremities

2. Occlusive disease of lower extremities

3. Abdominal angina

Aim: To be able to diagnose, to know the clinic chronic and acute ischemia of lower extremities, depending on the causes, clinical features of disease and to justify the conservative and surgical treatment

Professional oriented students:

Obliterating diseases of the extremities are the first place for the clinical importance and frequency and form a core group of organic arteriopathy, which are accessible to surgical treatment.

Statistics show an increase in acute arterial embolism and thrombosis - severe complications, which is necessary to meet the doctors of all specialties. However, the problem of care for patients with this disease is still far from solved, as evidenced by the high mortality

rate - from 20 to 35% and high frequency of limb amputation at the gangrene - almost 20% of patients.

Methodology for practical work

The practical part of the session 9.00 - 12.00

An algorithm for communication of students with patients, which is seen on the subject (communication skills):

Greet and identify himself.

The face should be welcoming smile - this allows you to establish a trust relationship with the patient.

A patient in a pleasant form should explain the purpose of the visit, the subject and the duration of the conversation and get his consent.

If a patient only comes to the hospital to conduct correctly, and quiet conversation with his relatives, which together with the doctor to inform them about the previous diagnosis, hospitalization, for some surveys, which are scheduled to perform in the future.

Before the physical examination survey methods to explain what the patient survey will be carried out, indicate some discomfort and discomfort that may feel the patient at the time of the survey, noting bound by the survey in the diagnosis of this disease and to obtain his consent.

If you need transportation to the place of examination (visual room, X-ray, ultrasound study) to explain its need for the patient.

Prepare for the survey (for data pathologies meant inspection, palpation limb aortoarteriografiya, ultrasound vascular legs, Doppler) - wash your hands with warm water, put on signets, prepare tools for the performance of other diagnostic manipulation.

To hold something or other planned medical examination or manipulation.

Together with the attending physician in the correct and easy to understand format patient to explain the results of either survey.

Involve family and patient to talk in simple terms to explain to them the results of the survey data, and in the presence of previous surveys to compare their results, be sure to

ascertaining whether they understand your explanations.

Must be only in the presence physician to substantiate the feasibility of surgical intervention for the treatment of this disease to supervise the patient.

Following surgical treatment only in the presence of the attending physician and with his consent should communicate the results of surgical intervention the patient and his relatives as well as the possibility of this or early or late postoperative complications.

Under the conditions of examination of patients in the postoperative period should be explained to the patient as true to perform hygiene procedures and the like.

In polite to get consent from the patient to participate in the ligation.

Together with your doctor to explain to the patient, and when the needs and next of kin of those or other actions regarding manipulations that have been implemented or planned to run in the future as well as the tactics of the subsequent treatment.

Finish the conversation should always be the wish of the patient the most rapid recovery.

Work 1

1. Collection of complaints, history, examination of the patient.
2. Identification of clinical symptoms and instrumental.
3. Grouping symptoms syndromes.
4. Determination of the leading syndrome.

Work 2. Browsing the Internet, reading room with cathedral library topical

literature.

Program self-students

1. The anatomic and functional features of arteries of lower extremities
2. The etiology, pathogenesis and classification of chronic lower limb ischemia
3. The etiology, pathogenesis and classification of acute lower limb ischemia.
4. The mechanism of action and dose antispasmodics, analgesics, anticoagulants, antiplatelet agents, angioprotectors and vitamin preparations/

Break - 12.00-12.30

Seminar discussion of theoretical issues - 12.30-14.00

Theme № 1 obliterating atherosclerosis of lower extremities

Etiology and pathogenesis of obliterative atherosclerosis of lower extremities.

Classification of chronic ischemia on Fontane.

Classification of chronic ischemia and the level of occlusion of arteries in obliterating atherosclerosis of A.A. Shalimov.

Modern theory and risk factors in the development of atherosclerosis.

Methods of the arterial system.

Complications of atherosclerotic lesions of lower limb arteries and methods for their prevention.

Definition, clinical characteristics and methods of surgical treatment of Leriche syndrome.

Indications and contraindications for conservative treatment of obliterative atherosclerosis of arteries of lower extremities.

Indications and contraindications for surgical treatment of obliterative atherosclerosis of arteries of the lower extremities.

Early postoperative complications of reconstructive operations on arteries of lower

extremities in obliterating atherosclerosis and methods for their prevention.

Rehabilitation of patients who had undergone reconstructive surgery on the aorta and major arteries.

Modern methods aortoarteriografii, complications of aortography and methods of prevention.

Methods to reduce the concentration of cholesterol and lipoproteins in blood plasma (pharmacological, instrumental).

Theme № 2 obliterating endarteriit lower extremities

Etiology and pathogenesis of obliterative endarteriitis lower extremities.

Classification of obliterative endarteriitis lower limbs Shabanov and fountains.

Features of clinical course of obliterative endarteriitis lower extremities.

Differential diagnosis of obliterative endarteriitis lower extremities with obliterative atherosclerosis.

Differential diagnosis of obliterative endarteriitis lower extremities with diabetic angiopathy, Raynaud's syndrome, nonspecific cryoglobulinemia.

Indications and contraindications for conservative treatment of obliterative endarteriitis lower extremities.

Principles of conservative treatment of obliterative endarteriitis lower extremities

Indications and contraindications for surgical treatment of obliterative endarteriitis lower extremities, methods of surgical treatment.

Rehabilitation of patients with obliterative endarteriitom lower extremities.

Theme № 3 abdominal angina

Causes of abdominal ischemic syndrome

Clinical characteristics of abdominal ischemic syndrome

Classification of abdominal ischemic syndrome

Differential diagnosis of abdominal ischemic syndrome.

Surgical tactics and methods of surgical treatment of abdominal ischemic syndrome.

Features of the postoperative period after surgery for abdominal ischemic syndrome.

Indications for conservative treatment, drugs that are used.

Break - 14.00-14.15

Hour self-study students - 14.15-15.00

- Tutorial test licensing examinations «Step 2»;
- Assessment of students who have not passed on the eve of the test control system «Moodle»;
- Letting students practical skills in the corresponding entry in matrikulyar book.

Sample test items and situational challenges.

1. Patient 64 years old, complained of rapid fatigue when walking, the feeling of coldness in the lower extremities, the appearance of pain in the lower leg muscles during walking a distance of 150-200 meters is ill about 12 years in the past 3 years noted the deterioration. When viewed from the skin of the lower extremities with a pale shade, cool at the feet, hyperkeratosis, poor body hair on the shins. Ripple in all arteries of both lower extremities (foot artery, popliteal, femoral) is absent. Diagnosis?

2. Sick 29 years old, was admitted with complaints of rapid fatigue, feeling cold in the lower extremities, the appearance of pain in the muscles of legs at a distance of 300 meters had felt unwell for 6 years and connects onset of supercooling. The general condition of the patient was satisfactory. Skin of the lower extremities at the level of the feet and lower third of the

tibia with a pale shade, cool to the touch, delicate, dry. Ripple in the arteries of the lower extremity is determined by the femoral artery at the knee - is weakened, the arteries of the foot - is absent. Ripple in the right thigh and popliteal arteries is satisfactory, at the foot arteries - is absent. Diagnosis?

3. The patient, 61 years old, was admitted to the vascular department with complaints of constant freezing toes, rapid fatigue and the appearance of pain in the muscles of legs, thighs, buttocks and sometimes when walking at a distance of 120-150 meters Sick for 6 years, the deterioration of their condition noted in last year. Above the abdominal aortic systolic murmur auscultated. On examination the skin of the lower extremities, with a pale shade, especially at the feet, dry and cool to the touch. Ripple in the peripheral arteries of the lower extremities is absent at all levels. Diagnosis?

4. What operations are used in obliterating atherosclerosis of the aorta and arteries?

- A. Saphenektomy;
- B. Embolectomy;
- C. Endarterectomy, bypass surgery, prosthetics.
- D. Operation Troyanov-Trendelenburg, Babcock;
- E. Operation Linton, Kukketa.

5. Please provide the most frequent complications of reconstructive operations in arteriosclerosis obliterans of the aorta and arteries of the lower extremities.

- A. Acute thrombophlebitis in the great saphenous vein;
- B. Acute thrombophlebitis in the small saphenous vein;
- C. Thrombosis of the inferior vena cava;
- D. Thrombosis segment reconstruction;

E. Chronic venous insufficiency.

6. Leriche syndrome develops:

A. At an atherosclerotic occlusion of the subclavian artery;

B. At an atherosclerotic occlusion of the popliteal artery;

C. At an atherosclerotic occlusion of the femoral artery;

D. At an atherosclerotic occlusion of terminal part of the abdominal aorta or common, external iliac arteries;

E. At an atherosclerotic occlusion of arteries shins.

7. What complications may arise during percutaneous catheterization of the aorta by Seldinger?

A. Bleeding, thrombosis, embolism.

B. Acute thrombophlebitis leg veins.

C. Relaxation of the diaphragm.

D. Thrombosis of the subclavian vein.

E. Endocarditis.

The student must know:

1. The etiology of atherosclerotic lesions and endarteriitis lower extremities.

2. Classification of chronic lower limb ischemia by Fontane.

3. Classification of atherosclerotic lesions at the level of occlusion (AA Shalimov).

4. Definition, clinical characteristics and treatment methods Leriche syndrome.

5. Indications and contraindications for surgical treatment of obliterative atherosclerosis endarteriitis and lower limb arteries.
6. Methods of the arterial system.
7. The differential diagnosis of obliterating atherosclerosis and obliterating endarteriitis arteries of the lower extremities.
8. Rehabilitation of patients who had undergone reconstructive surgery on the aorta and major arteries at the atherosclerotic lesions.
9. Methods to reduce the concentration of cholesterol and lipoproteins in blood plasma (pharmacological, instrumental).
10. The aetiology of abdominal ischemic syndrome.
11. Classification of abdominal ischemic syndrome ..
12. Clinical characteristics of abdominal ischemic syndrome.
13. The differential diagnosis of abdominal ischemic syndrome.
14. Surgical tactics in abdominal ischemic syndrome.
15. Complications of abdominal ischemic syndrome.
16. Features of the postoperative period after surgery for abdominal ischemic syndrome.

The student should be able to:

1. To assess the aorto-Arteriogram.
2. Apply thrombolytic drugs, and anticoagulants.
3. Appoint conservative therapy in obliterating atherosclerosis and occlusive disease of the lower extremities.
4. Determine the ripple in the typical spots on the major arteries of the lower extremities.

5. Rate this result is coagulation.

The answers to tests and situational tasks:

1 - obliterating atherosclerosis of lower extremities, Leriche, chronic arterial insufficiency II B degree.;

2 - obliterating endarteriitis lower extremities, chronic arterial insufficiency II A degree.

3 - obliterating atherosclerosis of lower limb arteries. Bilateral Leriche. chronic arterial insufficiency II degree.

4 - C

5 - D

6 - D

7 - A

Methodical instruction for lesson № 11

TOPIC: Varicose veins of lower extremities. Postthrombotic syndrome.

Lymphedema.

Practical - 6 hours

Topics: 1. Varicose veins of lower extremities.

2. Postthrombotic syndrome.

3. Lymphedema.

Purpose: To be able to diagnose varicose disease according to stage of disease, clinical features, to substantiate the diagnosis, methods of conservative and surgical treatment. Teach diagnosis, differential diagnosis, research methods, the choice of treatment, choice of surgical method of reconstruction of venous thrombosis, postthrombotic syndrome, and lymphedema.

Professional oriented students:

Varicose disease is one of the most common surgical disease, which occurs in 12-17% of the population. It is more common in middle age, and its complication as venous ulcers, chronic dermatitis, thrombophlebitis, bleeding from varicose veins often leads to lower efficiency, as is sometimes the cause of disability.

Thrombosis of the venous system occur in 27,4-41,0% of all cases of pathology of the venous system. Thrombosis of the venous system is accompanied by a high level of complications, which lead to postthrombotic syndrome, and cause pulmonary embolism. Postthrombotic syndrome is diagnosed in 0,3-0,4% of cases as a result of delayed or full treatment of acute deep vein thrombosis or thrombosis of the inferior vena cava.

Correction of metastatic spread remains a pressing problem of modern surgery. In

connection with the development and improvement of special methods of research of the lymphatic system, the introduction of the practice of microsurgical techniques, new directions in the treatment of lymphedema - performing operations directly on the lymphatic system.

Methodology for practical work

The practical part of the session 9.00 - 12.00

Algorithm for communication of students with patients with any pathology, which is seen on the subject (communication skills):

1. Greet and identify himself.
2. The face should be welcoming smile - this allows you to establish a trust relationship with the patient.
3. A patient in a pleasant form should explain the purpose of the visit, the subject and the duration of the conversation and get his consent.
4. If a patient only comes to the hospital to conduct correctly, and quiet conversation with his relatives, which together with the doctor to inform them about the previous diagnosis, hospitalization, for some surveys, which are scheduled to perform in the future.
5. Before the physical examination survey methods to explain what the patient survey will be carried out, indicate some discomfort and discomfort that may feel the patient at the time of the survey, noting bound by the survey in the diagnosis of this disease and to obtain his consent.
6. If you need transportation to the place of examination (visual room, X-ray, ultrasound study) to explain its need for the patient.
7. Prepare for the survey (for data pathologies meant inspection, palpation limb aortoarteriografiya, ultrasound vascular feet, Doppler) - wash your hands with warm water, put on signets, prepare tools for the performance of other diagnostic manipulation.
8. To hold something or other planned medical examination or manipulation.
9. Together with the attending physician in the correct and easy to understand format patient to explain the results of either survey.
10. Involve family and patient to talk in simple terms to explain to them the results of

the survey data and in the presence of previous surveys to compare their results, be sure to ascertaining whether they understand your explanations.

11. Must be only in the presence physician to substantiate the feasibility of surgical intervention for the treatment of this disease to supervise the patient.

12. Following surgical treatment only in the presence of the attending physician and with his consent should communicate the results of surgical intervention the patient and his relatives as well as the possibility of this or early or late postoperative complications.

13. Under the conditions of examination of patients in the postoperative period should be explained to the patient as true to perform hygiene procedures and the like.

14. In polite to get consent from the patient to participate in the ligation.

15. Together with your doctor to explain to the patient, and when the needs and next of kin of those or other actions regarding manipulations that have been implemented or planned to run in the future as well as the tactics of the subsequent treatment.

16. Finish the conversation should always be the wish of the patient the most rapid recovery.

Work 1

1. Collection of complaints, history, examination of the patient.
2. Identification of clinical symptoms and instrumental.
3. Grouping symptoms syndromes.
4. Determination of the leading syndrome.
5. Interpretation of laboratory - instrumental data
6. Rationale preliminary diagnosis
7. Differential diagnosis.
8. Formulation of clinical diagnosis.
9. Appointment of differentiated treatment programs according to the clinical protocol

Work 2. Browsing the Internet, reading room with cathedral library topical

literature.

Break - 12.00-12.30

Seminar discussion of theoretical issues - 12.30-14.00

Theme № 1 Varicose veins of lower extremities.

1. Etiology and pathogenesis of varicose veins.
2. Clinical characteristics of varicose veins.
3. Classification of varicose veins.
4. Methods and indications for phlebography.
5. Functional Tests to determine the state of valve surface, communicative and deep veins of the lower extremities.
6. Indications and contraindications for surgical treatment of varicose veins of lower extremities.
7. Sequence of operations saphenectomy.
8. Causes of recurrence of varicose veins of the lower extremities after saphenectomy, methods of prevention.
9. Repeated operations in case of recurrent varicose veins of lower extremities.

Theme № 2 Postthrombotic syndrome

1. Causes of postthrombotic syndrome.
2. Classification of postthrombotic syndrome
3. Clinic postthrombotic syndrome
4. Diagnosis of postthrombotic syndrome
5. Differential diagnosis of postthrombotic syndrome
6. Kosevativnoe treatment postthrombotic syndrome

7. Surgical treatment of postthrombotic syndrome
8. Rehabilitation of patients with postthrombotic syndrome

Theme № 3 Lymphedema.

1. Etiology and pathogenesis of lymphedema.
2. Clinical characteristics of lymphedema.
3. Classification of lymphedema.
4. Diagnosis: lymphography.
5. Methods of conservative treatment.
6. Indications for surgical treatment.
7. Methods of surgical treatment for lymphedema.

Break - 14.00-14.15

Hour self-study students - 14.15-15.00

- Tutorial test licensing examinations «Step 2»;
- Assessment of students who have not passed on the eve of the test control system «Moodle»;
- Letting students practical skills in the corresponding entry in matrikulyar book.

Sample test items and situational challenges.

1. A patient admitted to hospital with a diagnosis: Varicose veins the left lower extremity. At the examination revealed only varicose saphenous veins of legs without edema. What stage of varicose veins is in a patient?
2. A patient admitted to hospital with a diagnosis: Varicose veins left lower limb,

chronic venous insufficiency I degree. What kind of treatment the patient is the best?

3. How much blood are flows through the superficial veins?

- a. 10-15%
- b. 5%
- c. 30-40%
- d. 70-80%
- e. 90%

4. Where are falls the great saphenous vein?

- A. Femoral vein
- B. Calf veins
- C. Popliteal vein
- D. External iliac vein
- E. Vena cava inferior

5. Where are runs a small subcutaneous vein?

- A. Popliteal vein
- B. Vena cava inferior
- C. External iliac vein
- D. Thigh vein
- E. Calf veins

Source of knowledge and skills

The student must know:

1. The aetiology and pathogenesis of varicose disease.
2. Clinical characteristics of venous insufficiency.
3. Methods of examination of the venous system of lower limbs.
4. Functional Tests to determine the state of valve surface, communicative and deep

veins of the lower extremities.

5. Indications and contraindications for surgical treatment of varicose veins of lower extremities.

6. Sequence of operations saphenectomy.

7. Causes of recurrence of varicose veins of the lower extremities after saphenectomy, methods of prevention.

8. The etiology, pathogenesis, conditions postthrombotic syndrome.

9. Classification of postthrombotic syndrome.

10. Clinical manifestations of postthrombotic syndrome.

11. Indications and contraindications for surgical treatment of postthrombotic syndrome.

12. Indications and contraindications for surgical treatment in postthrombotic syndrome.

14. Clinical manifestations of postthrombotic syndrome.

15. Clinical manifestations of postthrombotic syndrome.

16. Anticoagulants, thrombolytic, fibrinolytic drugs.

17. Aetiology, pathogenesis lymphedema.

18. Classification of lymphedema.

19. Clinical manifestations of lymphedema of the lower extremities.

20. Methods of studying the lymphatic system.

21. Indications and methods for performing lymphography.

22. Indications and contraindications for surgical treatment of lymphedema.

23. Indications and methods of conservative treatment of lymphedema.

24. Differential diagnosis limfedematic limbs

The student should be able to:

1. Carry out functional tests to determine the status of valves surface, communicative and deep veins of the lower extremities.
2. Rate dopplerometry.
3. To evaluate clotting system.
4. To evaluate anticoagulant system.
5. Rate venogram.
6. Sample Rate Homans, Levenberg, Moses.
7. Rate limphogram.
8. Conduct a differential diagnosis lymphostasis with vascular pathology of the lower extremities.
9. Appoint conservative treatment lymphostasis.

The answers to tests and situational tasks:

- 1 - I
- 2 - Elastic compression
- 3 - A
- 4 - A
- 5 - A

Information:

Basic:

Guidelines made

ass.pof. Kostiv S.Ya.

Обсуждено на заседании кафедры

" 11" января 2013 р. протокол № 9

Methodological instruction for students 5-year

Methodical instruction for lesson № 12

Topic: Thrombosis of main veins.

Practical - 6 hours

Topics: 1. Deep vein thrombosis in the inferior vena cava.

2. Deep vein thrombosis in the superior vena cava.

3. Thrombosis of superficial veins.

Purpose: To be able to diagnose, to know the clinic vein thrombosis, depending on the causes, clinical features of disease, and to justify the conservative and surgical treatment

Professional oriented students:

Venous thrombosis - an acute disease characterized by the formation of a blood clot in a vein with more or less pronounced inflammatory process and a violation of the blood flow. The presence of inflammatory component in the area of thrombosis determine the other name of this disease - thrombophlebitis.

This complication frequently encountered in the postoperative period, averaging 27-30%. The importance of prevention, early diagnosis and treatment phlebemphraxis due to the fact that 2-10% of patients developed venous thrombosis is threatening complications such as pulmonary embolism (PE), with 0,26% of the cases it becomes a cause of death. Pulmonary embolism and deep vein thrombosis as a state with common pathogenetic roots, unite the concept of venous thromboembolism (embolic complications). The number of patients with a feasibility study of the main disease is increasing every year.

Methodology for practical work

The practical part of the session 9.00 - 12.00

Algorithm for communication of students with patients with any pathology, which is seen on the subject (communication skills):

1. Greet and identify himself.
2. The face should be welcoming smile - this allows you to establish a trust relationship with the patient.
3. A patient in a pleasant form should explain the purpose of the visit, the subject and the duration of the conversation and get his consent.

12. Following surgical treatment only in the presence of the attending physician and with his consent should communicate the results of surgical intervention the patient and his relatives as well as the possibility of this or early or late postoperative complications.

13. Under the conditions of examination of patients in the postoperative period should be explained to the patient as true to perform hygiene procedures and the like.

14. In polite to get consent from the patient to participate in the ligation.

15. Together with your doctor to explain to the patient, and when the needs and next of kin of those or other actions regarding manipulations that have been implemented or planned to run in the future as well as the tactics of the subsequent treatment.

16. Finish the conversation should always be the wish of the patient the most rapid recovery.

Work 1

1. Collection of complaints, history, examination of the patient.
2. Identification of clinical symptoms and instrumental.
3. Grouping symptoms syndromes.
4. Determination of the leading syndrome.
5. Interpretation of laboratory - instrumental data
6. Rationale preliminary diagnosis
7. Differential diagnosis.
8. Formulation of clinical diagnosis.
9. Appointment of differentiated treatment programs according to the clinical protocol

Work 2. Browsing the Internet, reading room with cathedral library topical literature.

Program self-students

1. Anatomical functional features of the veins of the upper and lower extremities.

2. The etiology, pathogenesis and classification of thrombosis.
3. Factors convolution and protivosvertochnoy systems.
4. The mechanism of thrombosis

Break - 12.00-12.30

Seminar discussion of theoretical issues - 12.30-14.00

Theme № 1 Deep vein thrombosis in the vena cava inferior.

1. Etiology of deep vein thrombosis in the vena cava inferior
2. Clinical characteristics of deep vein thrombosis in the vena cava inferior.
3. Classification of deep vein thrombosis in the vena cava inferior
4. Methods and indications for phlebography.
5. Diagnosis of deep vein thrombosis in the vena cava inferior
6. Indications to surgical treatment of deep vein thrombosis in the vena cava inferior
7. Contraindications to surgical treatment of deep vein thrombosis in the vena cava inferior.
8. Conservative treatment of deep vein thrombosis in the vena cava inferior.
9. Surgical treatment of deep vein thrombosis in the vena cava inferior

Theme № 2 Deep vein thrombosis in the vena cava superior.

1. Etiology of deep vein thrombosis in the vena cava superior
2. Clinical characteristics of deep vein thrombosis in the vena cava superior.
3. Classification of deep vein thrombosis in the vena cava superior
4. Methods and indications for phlebography.
5. Diagnosis of deep vein thrombosis in the vena cava superior

6. Indications to surgical treatment of deep vein thrombosis in the vena cava superior
7. Contraindications to surgical treatment of deep vein thrombosis in the vena cava superior.
8. Conservative treatment of deep vein thrombosis in the vena cava superior.
9. Surgical treatment of deep vein thrombosis in the vena cava superior

Theme № 3 Thrombosis of superficial veins.

1. The etiology of thrombosis of superficial veins
2. The clinical characteristics of thrombosis of superficial veins.
3. Classification of thrombosis of superficial veins
4. Methods and indications for ultrasound.
5. Diagnosis of thrombosis of superficial veins
6. Indications to surgical treatment of thrombosis of superficial veins
7. Contraindications to surgical treatment of superficial venous thrombosis.
8. Conservative treatment of superficial venous thrombosis.
9. Surgical treatment of thrombosis of superficial veins

Break - 14.00-14.15

Hour self-study students - 14.15-15.00

- Tutorial test licensing examinations «Step 2»;
- Assessment of students who have not passed on the eve of the test control system «Moodle»;
- Letting students practical skills in the corresponding entry in matrikulyar book.

Sample test items and situational challenges.

1. The patient complains on burning pain in the limbs and the presence of painful dense strand of progress varicose veins in the leg. What is the most likely diagnosis in a patient?

2. The patient complains of burning pain in the limbs and the presence of painful dense strand of progress varicose veins in the leg with the transition to the lower third of the thigh. What is the most likely diagnosis in a patient?

3. Edema of lower limbs characteristic:

- A. Thrombosis of the inferior vena cava
- B. Leriche
- C. Aortic aneurysm
- D. Paget's Syndrome-Schröter
- E. Thrombosis of superior vena cava

4. Violation of the sensitivity characteristic:

- A. Artery Embolism
- B. Varicose
- C. Deep vein thrombosis
- D. Subcutaneous thrombophlebitis
- E. Lymphedema

5. Paresis of the limbs is characteristic:

- A. A. Atherothrombosis
- B. B. Varicose
- C. C. DVT
- D. D. Subcutaneous thrombophlebitis
- E. E. Lymphedema

Source of knowledge and skills

The student must know:

1. The etiology, pathogenesis, conditions of thrombosis of the venous system.

- 2 Classification of thrombosis of the venous system.
3. Clinical manifestations of acute thrombophlebitis of subcutaneous veins of the lower extremities.
4. Indications and contraindications for surgical treatment of acute thrombophlebitis of subcutaneous veins of the lower extremities.
5. Methods of operating the elimination of acute thrombophlebitis of subcutaneous veins of the lower extremities.
6. Indications and contraindications for conservative treatment of acute thrombophlebitis of subcutaneous veins of the lower extremities.
7. Clinical manifestations of venous thrombosis shins.
8. Clinical manifestations of acute ilio-femoral segment.
9. Clinical manifestations of thrombosis of the inferior vena cava.
10. Acute thrombosis of the hepatic veins - syndrome Budd-Hiari.
11. Clinical manifestations of the syndrome Pedzhetta-Shrettera.
12. Clinical manifestations of blue flegmazi, treatment, prognosis.
13. Anticoagulants, thrombolytic, fibrinolytic drugs.

The student should be able to:

1. Carry out functional tests to determine the status of valves surface, kommunikantnyh and deep veins of the lower extremities.
2. Rate ultrasound.
3. To evaluate clotting system.
4. To evaluate anticoagulant system.
5. Rate venogram.

6. Appoint conservative treatment in Thrombosis

The answers to tests and situational tasks:

1 - Thrombophlebitis of subcutaneous veins.

2 - Ascending thrombophlebitis of subcutaneous veins

3 - A

4 – A

5 - A

Обсуждено на заседании кафедры

" 11" января 2013 р. протокол № 9

Methodical instruction for students V- years

(Vascular Surgery)

Lesson № 10 (PRACTICAL - 6 hours)

THEME: Injuries vessels.

Topics: 1. Trauma arteries

2. Trauma veins

3. Combined vascular injury

Purpose: To be able to diagnose, to know the clinic injuries limb vessels, depending on the causes, clinical features of disease, and to justify the conservative and surgical treatment

Professional oriented students:

Until recently, injury and damage to blood vessels were considered pathological, specific wartime. Nevertheless, many domestic and foreign authors have convincing evidence of a significant increase in the number of injuries of major blood vessels in time of peace, which in the overall structure of injury reach 2%.

The rapid development of industry and technology, agricultural mechanization, household contribute to the high level of injuries. This situation increases the importance of emergency angiosurgery in addressing these important social objectives, as a reduction of disability and reduce the time not disability, early medical and vocational rehabilitation of victims.

Further improvement in the quality of treatment of injuries of major vessels is dependent on improvements in diagnostic techniques, the introduction of new diagnostic and medical equipment, developing operational methods, the introduction of modern science, pharmacology, rehabilitation, rational organization of the Vascular Service.

In peacetime, the share of damage to major vessels of the upper extremities account for 32,3%, lower extremities - 58,8%.

Methodology for practical work

The practical part of the session 9.00 - 12.00

Algorithm for communication of students with patients with any pathology, which is seen on the subject (communication skills):

1. Greet and identify himself.
2. The face should be welcoming smile - this allows you to establish a trust relationship with the patient.
3. A patient in a pleasant form should explain the purpose of the visit, the subject and the duration of the conversation and get his consent.
4. If a patient only comes to the hospital to conduct correctly, and quiet conversation with his relatives, which together with the doctor to inform them about the previous diagnosis, hospitalization, for some surveys, which are scheduled to perform in the future.
5. Before the physical examination survey methods to explain what the patient survey will be carried out, indicate some discomfort and discomfort that may feel the patient at the time of the survey, noting bound by the survey in the diagnosis of this disease and to obtain his consent.
6. If you need transportation to the place of examination (visual room, X-ray, ultrasound study) to explain its need for the patient.
7. Prepare for the survey (for data pathologies meant inspection, palpation limb aortoarteriograffiya, ultrasound vascular leg doplerograffiya) - wash your hands with warm water, put on signets, prepare tools for the performance of other diagnostic manipulation.
8. To hold something or other planned medical examination or manipulation.
9. Together with the attending physician in the correct and easy to understand format patient to explain the results of either survey.
10. Involve family and patient to talk in simple terms to explain to them the results of the survey data and in the presence of previous surveys to compare their results, be sure to

ascertaining whether they understand your explanations.

11. Required only in the presence of the attending physician to substantiate the feasibility of surgical intervention for the treatment of this pathology in charge of the patient.

12. Following surgical treatment only in the presence of the attending physician and with his consent should communicate the results of surgical intervention the patient and his relatives as well as the possibility of this or early or late postoperative complications.

13. Under the conditions of examination of patients in the postoperative period should be explained to the patient as true to perform hygiene procedures and the like.

14. In polite to get consent from the patient to participate in the ligation.

15. Together with your doctor to explain to the patient, and when the needs and the immediate family, those or other actions regarding manipulations that have been implemented or planned to run in the future as well as the tactics of the subsequent treatment.

16. Finish the conversation should always be the wish of the patient the most rapid recovery.

Work 1

1. Collection of complaints, history, examination of the patient.
2. Identification of clinical symptoms and instrumental.
3. Grouping symptoms syndromes.
4. Determination of the leading syndrome.
5. Interpretation of laboratory - instrumental data
6. Rationale preliminary diagnosis
7. Differential diagnosis.
8. Formulation of clinical diagnosis.
9. Appointment of differentiated treatment programs according to the clinical protocol

Work 2. Browsing the Internet, reading room with cathedral library topical literature.

Program self-students

1. Anatomical functional characteristics of arteries and veins of the lower extremities
2. Anatomical functional characteristics of arteries and veins of upper extremities
3. Etiology of vascular injury
4. Pathogenesis of vascular injury
5. Classification of vascular injury
6. Clinic injuries arteries
7. The clinic combined injuries
8. Diagnosis of vascular injuries
7. Temporary stop bleeding
8. Final stop bleeding
9. Factors convolution and coagulation systems
10. Postoperative management of patients with vascular injury

Break - 12.00-12.30

Seminar discussion of theoretical issues - 12.30-14.00

Theme № 1 Trauma arteries

1. Causes of injury of the arteries.
2. Clinical characteristics of injuries of the arteries.
3. Classification of injuries of the arteries.
4. Differential diagnosis of arterial injury.
5. Surgical tactics in injuries of the arteries
6. Methods of operative treatment of injuries of the arteries.
7. Features of the postoperative period after surgery on the injured arteries.

8. Indications for conservative treatment, drugs that are used.
9. Anticoagulants, fibrinolytic thrombolytic drugs.
10. Control methods for convolution system, their characteristics.

Theme № 2 Trauma veins

1. Causes of injury veins.
2. Clinical characteristics of injured veins.
3. Classification of injuries veins.
4. Differential diagnosis of venous injury.
5. Surgical tactics in injuries veins
6. Methods of operative treatment of injured veins.
7. Features of the postoperative period after surgery on the injured veins.
8. Indications for conservative treatment, drugs that are used.
9. Anticoagulants, fibrinolytic thrombolytic drugs.
10. Control methods for convolution system, their characteristics.

Theme № 3 Combined vascular injury

1. Causes of combined injuries of the vessels.
2. Clinical characteristics of combined injuries of the vessels.
3. Classification of vascular injury.
4. Differential Diagnosis of combined injuries of the vessels.
5. Surgical tactics in combined injuries of vessels
6. Methods of surgical treatment of combined injuries of the vessels.

7. Features of the postoperative period after surgical intervention for combined injuries of the vessels.
8. Indications for conservative treatment, drugs that are used.
9. Anticoagulants, fibrinolytic thrombolytic drugs.
10. Control methods for convolution system, their characteristics.

Break - 14.00-14.15

Hour self-study students - 14.15-15.00

- Tutorial test licensing examinations «Step 2»;
- Assessment of students who have not passed on the eve of the test control system «Moodle»;
- Letting students practical skills in the corresponding entry in matrikulyar book.

The seminars discussion of theoretical issues

Sample test items and situational problems.

1. A patient admitted to hospital with a gunshot wound in the lower groin ligament. Injury what vessel should be suspected?
2. A patient admitted to hospital with a gunshot wound in the popliteal fossa. Injury what vessel should be suspected?
 - A. Popliteal artery
 - B. Common femoral artery
 - C. Common iliac
 - D. Aorta
 - E. Internal iliac artery
3. Where, anatomically, is the most dangerous part brachial artery ligation:
 - A. No right answer
 - B. Distal separation of the deep artery of arm
 - C. In the middle
 - D. In the lower third of
 - E. Near the ulnar artery
4. The vessel should be bind:

- A. Near the injury
 - B. Distal from the injury site
 - C. On the middle of damage
 - D. It does not matter
 - E. In place of separation of the artery
5. Complications the stop bleeding by ligation of the vessel:
- A. Rebleeding
 - B. Ischemic contracture of the limbs
 - C. Trophic ulcer
 - D. The complications do not develop
 - E. Paresis of the limbs

The student should be able to:

1. To assess the aorto-arteriogramu
2. Rate coagulogram.
3. Evaluate the results ultrasound research
4. Apply thrombolytic drugs and anticoagulants.
5. Appoint conservative therapy for vascular injury
6. Determine the ripple in the typical spots on the major arteries of the lower extremities.
7. Apply methods to temporarily stop bleeding.
8. Appoint conservative therapy in acute blood loss.

The answers to tests and situational tasks:

1- Common femoral vein

2 - Popliteal artery

3 – A

4 – A

5 - A

" 11" января 2013 р. протокол № 9

METHODICAL INSTRUCTIONS FOR STUDENTS V YEARS

Lesson № 13

Topic: Pulmonary embolism.

Practical - 6 hours

Purpose: To be able to diagnose pulmonary embolism know the clinic, the clinical features of disease and to justify the conservative and surgical treatment

Professional oriented students:

VTE is a major cause of sudden death in people. It is difficult to 0,1-0,3% of surgical operations and is responsible for 20-40% of fatal cases. However, PE is not less frequently observed in medical patients, because of the prevalence of risk factors for this pathology.

Methodology for practical work

The practical part of the session 9.00 - 12.00

Algorithm for communication of students with patients with any pathology, which is seen on the subject (communication skills):

1. Greet and identify himself.
2. The face should be welcoming smile - this allows you to establish a trust relationship with the patient.
3. A patient in a pleasant form should explain the purpose of the visit, the subject and the duration of the conversation and get his consent.
4. If a patient only comes to the hospital to conduct correctly, and quiet conversation with his relatives, which together with the doctor to inform them about the previous diagnosis,

hospitalization, for some surveys, which are scheduled to perform in the future.

5. Before the physical examination survey methods to explain what the patient survey will be carried out, indicate some discomfort and discomfort that may feel the patient at the time of the survey, noting bound by the survey in the diagnosis of this disease and to obtain his consent.

6. If you need transportation to the place of examination (visual room, X-ray, ultrasound study) to explain its need for the patient.

7. Prepare for the survey (for data pathologies meant inspection, palpation limb aortoarteriograffiya, ultrasound vascular leg doplerograffiya) - wash your hands with warm water, put on signets, prepare tools for the performance of other diagnostic manipulation.

8. To hold something or other planned medical examination or manipulation.

9. Together with the attending physician in the correct and easy to understand format patient to explain the results of either survey.

10. Involve family and patient to talk in simple terms to explain to them the results of the survey data and in the presence of previous surveys to compare their results, be sure to ascertaining whether they understand your explanations.

11. Required only in the presence of the attending physician to substantiate the feasibility of surgical intervention for the treatment of this pathology in charge of the patient.

12. Following surgical treatment only in the presence of the attending physician and with his consent should communicate the results of surgical intervention the patient and his relatives as well as the possibility of this or early or late postoperative complications.

13. Under the conditions of examination of patients in the postoperative period should be explained to the patient as true to perform hygiene procedures and the like.

14. In polite to get consent from the patient to participate in the ligation.

15. Together with your doctor to explain to the patient, and when the needs and next of kin of those or other actions regarding manipulations that have been implemented or planned to run in the future as well as the tactics of the subsequent treatment.

16. Finish the conversation should always be the wish of the patient the most rapid

recovery.

Work 1

1. Collection of complaints, history, examination of the patient.
2. Identification of clinical symptoms and instrumental.
3. Grouping symptoms syndromes.
4. Determination of the leading syndrome.
5. Interpretation of laboratory - instrumental data
6. Rationale preliminary diagnosis
7. Differential diagnosis.
8. Formulation of clinical diagnosis.
9. Appointment of differentiated treatment programs according to the clinical protocol

Work 2. Browsing the Internet, reading room with cathedral library topical literature.

Program self-students

1. The anatomic and functional characteristics of veins of lower extremities and pelvis
2. Factors convolution and protivosvertochnoy systems.
3. The mechanism of thrombosis in the venous system.
4. The anatomic and functional features of pulmonary arteries
5. Principles of postoperative period

Break - 12.00-12.30

Seminar discussion of theoretical issues - 12.30-14.00

1. Terms of thrombosis in the venous system.
2. Indications for surgical and conservative treatment of venous thrombosis.

3. Principles of surgical and conservative treatment of venous thrombosis.
4. Classification of pulmonary embolism.
5. Peculiarities of hemodynamics of the right heart and pulmonary circulation.
6. Clinical manifestations of pulmonary embolism.
7. Clinical forms of pulmonary embolism (cardiac, pulmonary, cerebral).
8. ECG signs of pulmonary embolism.
9. Radiological signs of pulmonary embolism.
10. Contemporary pulmonary embolism diagnosis (determination of D-dimer, ultrasonography, angiopulmonografiya).
11. Differential diagnosis of pulmonary embolism with myocardial infarction.
12. Therapy of pulmonary embolism, the control of the convection of the blood system.
13. Indications and methods of surgical treatment of pulmonary embolism.
14. Indications and methods of endovascular interventions for pulmonary embolism.
15. Total prevention of pulmonary embolism.
16. Indications and contraindications to the use of vena filters.
17. Indications and methods of correction of pulmonary hypertension.

Break - 14.00-14.15

Hour self-study students - 14.15-15.00

- Tutorial test licensing examinations «Step 2»;
- Assessment of students who have not passed on the eve of the test control system «Moodle»;
- Letting students practical skills in the corresponding entry in matrikulyar book.

The workshops discuss theoretical issues

Sample test items and situational problems.

1. The patient admitted to the hospital with a diagnosis deep vein thrombosis left lower extremity. The patient suddenly began to worry shortness of breath, retrosternal pain. What complication can be suspected in a patient?
2. The patient admitted to the hospital with a diagnosis deep vein thrombosis left lower extremity. The patient suddenly began to worry shortness of breath, retrosternal pain. What method diagnosis should be used to refine the diagnosis?
3. What is the main danger the subcutaneous thrombophlebitis?
 - A. Pulmonary embolism
 - B. Venous insufficiency
 - C. Trophic ulcer
 - D. Gangrene fingers on the lower extremity
 - E. Paralysis
4. Palee skin is characteristic for:
 - A. Artery Embolism
 - B. Varicose
 - C. Deep phlebothrombosis
 - D. Postthrombotic syndrome
 - E. Phlegmon limb
5. Expressed cold extremities is characteristic for:
 - A. Atherothrombosis
 - B. Varicose
 - C. Deep phlebothrombosis
 - D. Postthrombotic syndrome
 - E. Phlegmon limb

The student should be able to:

1. Rate coagulogram.
2. Rate ECG.
3. Apply thrombolytic drugs, and anticoagulants.
4. Appoint conservative therapy in the body.

The answers to tests and situational tasks:

- 1 - Pulmonary embolism
- 2 - ECG
- 3 - A.
- 4 – A
- 5 - A

Обсуждено на заседании кафедры

" 11" января 2013 р. протокол № 9

MODULE 1. ABDOMINAL SURGERY

Text test questions

1. Acute appendicitis in the 1st phase is necessary to differentiate from:
 - A. * gastric ulcer
 - B. pancreatitis
 - C. cholecystitis
 - D. intestinal obstruction
 - E. strangulated hernia

2. After appendectomy the patient stands out of bed on:
 - A. * first day
 - B. second day
 - C. third day
 - D. fourth day
 - E. fifth day

3. After appendectomy to early postoperative complications belongs:
 - A. * peritonitis
 - B. intestinal fistula
 - C. ventral hernia
 - D. ligature fistula
 - E. colitis

4. After appendectomy to late postoperative complications belongs:
 - A. * intestinal fistula
 - B. appendicular infiltrate
 - C. pilephlebitis
 - D. peritonitis
 - E. colitis

5. Appendectomy after the treatment of appendicular infiltrate performed after:
 - A. * 2-4 months
 - B. 1-2 weeks
 - C. 3-4 weeks
 - D. 1-2 months
 - E. 3-5 days

6. Appendectomy, as a rule, is performed under such anaesthesia:
 - A. * intravenous anaesthesia
 - B. local anaesthesia
 - C. ether anaesthesia
 - D. conducting anaesthesia
 - E. endotracheal anaesthesia

7. Appendicular infiltrate appears after:
 - A. * 3-5 days
 - B. 1-2 days
 - C. 5-6 days
 - D. 7-8 days
 - E. 8-10 days

8. Appendicular infiltrate is treated:

- A. * conservative therapy, then surgery
 - B. only conservative therapy
 - C. puncture
 - D. drainage
 - E. only surgical treatment
9. Appendicular infiltrate is treated:
- A. * antibiotics, paranephral blockade, detoxication therapy
 - B. antiseptics, analgesia, antibiotics, anti-inflammatory therapy
 - C. antibiotics, diuretics, antispasmodic, anti-inflammatory therapy
 - D. analgesia, antibiotics, diuretics, anti-inflammatory therapy
 - E. anti-inflammatory drugs, paranephral blockade, detoxication therapy
10. Bartomier's sign is typical for:
- A. * acute appendicitis
 - B. acute cholecystitis
 - C. acute intestinal obstruction
 - D. food poisoning
 - E. acute pancreatitis
11. Black colour, fibrino-purulent fur, perforation are the signs of:
- A. * gangreno-perforative appendicitis
 - B. phlegmonous appendicitis
 - C. gangrenous appendicitis
 - D. catarrhal appendicitis
 - E. dystrophic appendicitis
12. Black colour, fibrino-purulent fur, pus in the lumen are the signs of:
- A. * gangrenous appendicitis
 - B. phlegmonous appendicitis
 - C. catarrhal appendicitis
 - D. gangreno-perforative appendicitis
 - E. dystrophic appendicitis
13. Blumberg's sign in Petit triangle is:
- A. * Gabay's sign
 - B. Rovsing's sign
 - C. Sitkovsky's sign
 - D. Obrastsow's sign
 - E. Kulenkampf's sign
14. Blumberg's sign is typical for:
- A. * acute appendicitis
 - B. acute thrombophlebitis
 - C. pneumothorax
 - D. food poisoning
 - E. bleeding ulcer
15. Causes of the appendicular infiltrate development:
- A. * late hospitalisation, misdiagnosed appendicitis
 - B. aggressive infection, impaired immunity
 - C. adhesions, increased immunity
 - D. peritonitis, abscessing
 - E. surgical trauma, infection

16. Characteristic changes in the general blood analysis in appendicitis:
- A. * neutrophil leucocytosis with deviation of the differential count to the left
 - B. neutrophil lymphocytosis with deviation of the differential count to the left
 - C. neutrophil eosinophilia with deviation of the differential count to the left
 - D. neutrophil leucocytosis with deviation of the differential count to the right
 - E. white cells neutrophilia with deviation of the differential count to the right
17. Chronic primary appendicitis - is the development of pathological changes in appendix after:
- A. * without the signs of acute appendicitis in anamnesis
 - B. acute appendicitis
 - C. appendicular infiltrate
 - D. appendicular abscess
 - E. pilephlebitis
18. Chronic residual appendicitis arises up after:
- A. * acute appendicitis
 - B. chronic appendicitis
 - C. colicks
 - D. recurrent appendicitis
 - E. primary chronic appendicitis
19. Chronic residual appendicitis arises up after:
- A. * appendicular infiltrate
 - B. chronic appendicitis
 - C. recurrent appendicitis
 - D. colicks
 - E. primary chronic appendicitis
20. Chronic residual appendicitis arises up after:
- A. * appendicular abscess
 - B. colicks
 - C. chronic appendicitis
 - D. recurrent appendicitis
 - E. primary chronic appendicitis
21. Conservative treatment of appendicular infiltrate is going on:
- A. * 1-2 weeks
 - B. 1 week
 - C. 3-4 weeks
 - D. 1-2 months
 - E. 2-4 months
22. Dunphy's sign is typical for:
- A. * acute appendicitis
 - B. acute cholecystitis
 - C. acute intestinal obstruction
 - D. food poisoning
 - E. acute pancreatitis
23. During appendectomy the most frequent complication is:
- A. * bleeding
 - B. infiltrate
 - C. leak of the sutures

- D. infecting
- E. peritonitis

24. Dyspeptic syndrome is characteristic for acute appendicitis in:

- A. * children
- B. females
- C. males
- D. pregnant
- E. elderly patients

25. Dyspeptic syndrome is characteristic for acute appendicitis in:

- A. * children
- B. females
- C. males
- D. pregnant
- E. elderly patients

26. For acute appendicitis is typical:

- A. * Kocher-Volkovitch's sign
- B. Ortner's sign
- C. Homans sign
- D. Sklyarov's sign
- E. Meyo-Robson sign

27. For acute appendicitis is typical:

- A. * Rovsing's sign
- B. Ortner's sign
- C. Homans sign
- D. Sklyarov's sign
- E. Meyo-Robson sign

28. For acute appendicitis is typical:

- A. * Sitkovsky's sign
- B. Ortner's sign
- C. Homans sign
- D. Sklyarov's sign
- E. Meyo-Robson sign

29. For acute appendicitis is typical:

- A. * Bartomier's sign
- B. Ortner's sign
- C. Homans sign
- D. Sklyarov's sign
- E. Meyo-Robson sign

30. For acute appendicitis is typical:

- A. * Dunphy's sign
- B. Ortner's sign
- C. Homans sign
- D. Sklyarov's sign
- E. Meyo-Robson sign

31. For acute appendicitis is typical:

- A. * Blumberg's sign

- B. Ortner's sign
- C. Homans sign
- D. Sklyarov's sign
- E. Meyo-Robson sign

32. For acute appendicitis is typical:

- A. * Voskresenky's sign
- B. Ortner's sign
- C. Homans sign
- D. Sklyarov's sign
- E. Meyo-Robson sign

33. For acute appendicitis is typical:

- A. * Rozdolsky's sign
- B. Ortner's sign
- C. Homans sign
- D. Sklyarov's sign
- E. Meyo-Robson sign

34. For acute appendicitis is typical:

- A. * Yaure-Rozanov's sign
- B. Ortner's sign
- C. Homans sign
- D. Sklyarov's sign
- E. Meyo-Robson sign

35. For acute appendicitis is typical:

- A. * Gabay's sign
- B. Ortner's sign
- C. Homans sign
- D. Sklyarov's sign
- E. Meyo-Robson sign

36. For acute appendicitis is typical:

- A. * Psoas sign
- B. Ortner's sign
- C. Homans sign
- D. Sklyarov's sign
- E. Meyo-Robson sign

37. For acute appendicitis is typical:

- A. * Obrastsow's sign
- B. Ortner's sign
- C. Homans sign
- D. Sklyarov's sign
- E. Meyo-Robson sign

38. For acute appendicitis typical t° is:

- A. * 38° C
- B. 37° C
- C. subfebrile
- D. 37-39° C
- E. 38-40° C

39. For appendectomy the most suitable surgical access is:
- A. * Volkovich-Dyakonov
 - B. McBurney
 - C. Lenander
 - D. Sprengel
 - E. Kocher
40. For pelvic appendicitis is characteristic the sign:
- A. * Kulenkampf's sign
 - B. Yaure-Rozanov sign
 - C. Sitkovsky's sign
 - D. Obrastsov's sign
 - E. Voskresensky's sign
41. For retrocecal appendicitis is characteristic the sign:
- A. * Yaure-Rozanov sign
 - B. Sitkovsky's sign
 - C. Obrastsov's sign
 - D. Voskresensky's sign
 - E. Kulenkampf's sign
42. For retrocecal appendicitis is characteristic the sign:
- A. * Gabay's sign
 - B. Sitkovsky's sign
 - C. Obrastsov's sign
 - D. Voskresensky's sign
 - E. Kulenkampf's sign
43. For retroperitoneal appendicitis is characteristic the sign:
- A. * Pasternatsky's
 - B. Sitkovsky's
 - C. Yaure-Rozanov
 - D. Rovzing's
 - E. Koer's
44. For the left-side appendicitis is typical:
- A. * The painfulness of the left iliac region
 - B. Expressed pain in a right lumbar area
 - C. Flank tenderness in right lower quadrant
 - D. Clinic of irritation of pelvic organs
 - E. Painfulness of anterior rectal wall and posterior vaginal vault
45. For the pelvic appendicitis is typical:
- A. * Clinic of irritation of pelvic organs
 - B. The painfulness of the left iliac region
 - C. Expressed pain in a right lumbar area
 - D. Flank tenderness in right lower quadrant
 - E. Peritoneal signs
46. For the pelvic appendicitis is typical:
- A. * Painfulness of anterior rectal wall
 - B. The painfulness of the left iliac region
 - C. Expressed pain in a right lumbar area
 - D. Flank tenderness in right lower quadrant

E. Peritoneal signs

47. For the pelvic appendicitis is typical:

- A. * Painfulness of posterior vaginal vault
- B. The painfulness of the left iliac region
- C. Expressed pain in a right lumbar area
- D. Flank tenderness in right lower quadrant
- E. Peritoneal signs

48. For the perforation of appendix is not characteristic:

- A. * Decrease of body temperature
- B. Acute pain in a right iliac area, especially expressed after false improvement
- C. Tension of the abdominal wall at first in a right iliac area, and then spreading on other departments
- D. Increasing swelling of abdomen
- E. Leucocytosis

49. For the retrocaecal appendicitis is not typical:

- A. * Volkovcha-Kocher's sign
- B. delayed diagnostics
- C. late entrance of patients in the hospital
- D. frequent development of destructive forms
- E. weak expressed signs of peritoneal irritation

50. For the retrocecal appendicitis is typical:

- A. * Yaure-Rozanov sign
- B. Rovsing's sign
- C. Blumberg's sign
- D. Voskresensky's sign
- E. Kulenkampf's sign

51. For the retrocecal appendicitis is typical:

- A. * Gabay's sign
- B. Rovsing's sign
- C. Blumberg's sign
- D. Voskresensky's sign
- E. Kulenkampf's sign

52. For the retrocecal appendicitis is typical:

- A. * Pasternatsky's sign
- B. Rovsing's sign
- C. Blumberg's sign
- D. Voskresensky's sign
- E. Kulenkampf's sign

53. For the retrocecal appendicitis is typical:

- A. * Psoas sign
- B. Rovsing's sign
- C. Blumberg's sign
- D. Voskresensky's sign
- E. Kulenkampf's sign

54. For the retrocecal appendicitis is typical:

- A. * Expressed pain in a right lumbar area

- B. Flank tenderness in right lower quadrant
- C. The painfulness of the left iliac region
- D. Clinic of irritation of pelvic organs
- E. Painfulness of anterior rectal wall and posterior vaginal vault

55. For the retroperitoneal appendicitis is typical:

- A. * Flank tenderness in right lower quadrant
- B. Peritoneal signs
- C. The painfulness of the left iliac region
- D. Clinic of irritation of pelvic organs
- E. Painfulness of anterior rectal wall and posterior vaginal vault

56. For the simple appendicitis is typical:

- A. * Rovsing's sign
- B. Blumberg's sign
- C. Yaure-Rozanov sign
- D. Voskresensky's sign
- E. Kulenkampf's sign

57. For the simple appendicitis is typical:

- A. * Sitkovsky's sign
- B. Blumberg's sign
- C. Yaure-Rozanov sign
- D. Voskresensky's sign
- E. Kulenkampf's sign

58. For the simple appendicitis is typical:

- A. * Bartomier's sign
- B. Blumberg's sign
- C. Yaure-Rozanov sign
- D. Voskresensky's sign
- E. Kulenkampf's sign

59. For the simple appendicitis is typical:

- A. * Dunphy's sign
- B. Blumberg's sign
- C. Yaure-Rozanov sign
- D. Voskresensky's sign
- E. Kulenkampf's sign

60. Gabay's sign is typical for:

- A. * acute appendicitis
- B. acute thrombophlebitis
- C. pneumothorax
- D. food poisoning
- E. bleeding ulcer

61. Hyperaemia, thickening, oedema of appendix are the signs of:

- A. * catarrhal appendicitis
- B. phlegmonous appendicitis
- C. gangrenous appendicitis
- D. gangreno-perforating appendicitis
- E. dystrophic appendicitis

62. Hyperemia, fibrino-purulent fur, pus the lumen are the signs of:
- A. * phlegmonous appendicitis
 - B. catarrhal appendicitis
 - C. gangrenous appendicitis
 - D. gangreno-perforative appendicitis
 - E. dystrophic appendicitis
63. In what location of appendix the rectal examination is the most informing?
- A. * Pelvic
 - B. Retrocaecal
 - C. Madian
 - D. Subhepatic
 - E. Retroperitoneal
64. Increased pain with coughing is:
- A. * Dunphy's sign
 - B. Rovsing's sign
 - C. Sitkovsky's sign
 - D. Obrastsov's sign
 - E. Kulenkampf's sign
65. Inexpressive abdominal pain in acute appendicitis is characteristic for:
- A. * elderly patients
 - B. children
 - C. females
 - D. males
 - E. pregnant
66. Inexpressive abdominal pain in acute appendicitis is characteristic for:
- A. * elderly patients
 - B. children
 - C. females
 - D. males
 - E. pregnant
67. Inexpressive leucocytosis in acute appendicitis is characteristic for:
- A. * elderly patients
 - B. females
 - C. children
 - D. pregnant
 - E. males
68. Inexpressive leucocytosis in acute appendicitis is characteristic for:
- A. * elderly patients
 - B. females
 - C. children
 - D. pregnant
 - E. males
69. Inexpressive muscular tension of anterior abdominal wall in acute appendicitis is characteristic for:
- A. * elderly patients
 - B. females
 - C. children

- D. pregnant
- E. males

70. Inexpressive muscular tension of anterior abdominal wall in acute appendicitis is characteristic for:

- A. * elderly patients
- B. females
- C. children
- D. pregnant
- E. males

71. Initially-gangrenous appendicitis differs from inflammatory-gangrenous form mostly developing in persons:

- A. * of elderly age
- B. children of early age
- C. pregnant in the first half of pregnancy
- D. pregnant in the second half of pregnancy
- E. with concomitant diseases

72. Kocher-Volkovitch's sign is typical for:

- A. * acute appendicitis
- B. acute cholecystitis
- C. acute intestinal obstruction
- D. food poisoning
- E. acute pancreatitis

73. Lymphoid hypoplasia determines the peculiarities of the clinical course of appendicitis in:

- A. * children
- B. elderly patients
- C. pregnant
- D. males
- E. females

74. Lymphoid hypoplasia determines the peculiarities of the clinical course of appendicitis in:

- A. * children
- B. elderly patients
- C. pregnant
- D. males
- E. females

75. Microhematuria is typical for such kind of appendicitis:

- A. * retroperitoneal
- B. retrocecal
- C. pelvic
- D. subhepatic
- E. left-side

76. Migration of pain to the right iliac area from epigastric is:

- A. * Kocher-Volkovitch's sign
- B. Rovsing's sign
- C. Sitkovsky's sign
- D. Obrastsov's sign
- E. Kulenkampf's sign

77. Modern method of appendectomy is:
- A. * laparoscopic
 - B. microlaparotomy
 - C. laparocentesis
 - D. laparotomy
 - E. ligation
78. Obrastsov's sign is typical for:
- A. * acute appendicitis
 - B. acute thrombophlebitis
 - C. pneumothorax
 - D. food poisoning
 - E. bleeding ulcer
79. On the line between the anterior-superior process of the iliac bone and umbilicus located the point:
- A. * McBurney's
 - B. Kalk's
 - C. Kehr's
 - D. Lenander's
 - E. Volkovich-Dyakonov
80. Only during the operation is possible the differential diagnostics of acute appendicitis with:
- A. * terminal ileitis
 - B. renal colic
 - C. acute pyelonephritis
 - D. acute paraproctitis
 - E. acute pancreatitis
81. Pain during digital examination of rectum - is:
- A. * Kulenkampf's sign
 - B. Obrastsov's sign
 - C. Voskresensky's sign
 - D. Kocher-Volkovitch's sign
 - E. Sitkovsky's sign
82. Pain during palpation in a lumbar region - is the sign:
- A. * Yaure-Rozanov sign
 - B. Sitkovsky's sign
 - C. Obrastsov's sign
 - D. Voskresensky's sign
 - E. Kulenkampf's sign
83. Pain during palpation in a lumbar region after taking away of the hand is the sign:
- A. * Gabay's sign
 - B. Sitkovsky's sign
 - C. Obrastsov's sign
 - D. Voskresensky's sign
 - E. Kulenkampf's sign
84. Pain during palpation in the Petit triangle - is the sign:
- A. * Yaure-Rozanov sign
 - B. Sitkovsky's sign
 - C. Obrastsov's sign

- D. Voskresensky's sign
 - E. Kulenkampf's sign
85. Pain during percussion by fingers of anterior abdominal wall - is:
- A. * Rozdolsky's sign
 - B. Obrastsow's sign
 - C. Sitkovsky's sign
 - D. Voskresensky's sign
 - E. Kulenkampf's sign
86. Pain during removing of the hand from abdominal wall after its pressing - is:
- A. * Shchotkin-Blumberg's sign
 - B. Rovsing's sign
 - C. Sitkovsky's sign
 - D. Obrastsow's sign
 - E. Kulenkampf's sign
87. Pain during sliding of hand on abdominal wall - is:
- A. * Voskresensky's sign
 - B. Sitkovsky's sign
 - C. Obrastsow's sign
 - D. Kocher-Volkovitch's sign
 - E. Bartomier-Mikhelson's sign
88. Pain in the iliac region during elevation of the leg - is:
- A. * Obrastsow's sign
 - B. Sitkovsky's sign
 - C. Kocher-Volkovitch's sign
 - D. Bartomier-Mikhelson's sign
 - E. Voskresensky's sign
89. Pain in the right iliac region by pushing of the left - is:
- A. * Rovsing's sign
 - B. Sitkovsky's sign
 - C. Obrastsow's sign
 - D. Voskresensky's sign
 - E. Kulenkampf's sign
90. Pain in the right iliac region during palpation of the iliac region on the left side - is:
- A. * Bartomier-Mikhelson's sign
 - B. Sitkovsky's sign
 - C. Obrastsow's sign
 - D. Voskresensky's sign
 - E. Kocher-Volkovitch's sign
91. Pain on extension of right thigh is:
- A. * Psoas sign
 - B. Rovsing's sign
 - C. Sitkovsky's sign
 - D. Obrastsow's sign
 - E. Kulenkampf's sign
92. Painfulness during palpation of Petit triangle is:
- A. * Yaure-Rozanov's sign

- B. Rovsing's sign
- C. Sitkovsky's sign
- D. Obrastsov's sign
- E. Kulenkampf's sign

93. Painfulness of posterior vaginal vault is typical for:

- A. * Pelvic appendicitis
- B. Retrocecal appendicitis
- C. Phlegmonous appendicitis
- D. Simple appendicitis
- E. Left-side appendicitis appendicitis

94. Psoas sign is typical for:

- A. * acute appendicitis
- B. acute thrombophlebitis
- C. pneumothorax
- D. food poisoning
- E. bleeding ulcer

95. Rapid destruction of the appendix in the course of acute appendicitis is characteristic for:

- A. * elderly patients
- B. children
- C. pregnant
- D. males
- E. females

96. Rapid destruction of the appendix in the course of acute appendicitis is characteristic for:

- A. * elderly patients
- B. children
- C. pregnant
- D. males
- E. females

97. Reduced reactivity of the organism influences on the peculiarities of the course of acute appendicitis in:

- A. * elderly patients
- B. females
- C. males
- D. pregnant
- E. children

98. Reduced reactivity of the organism influences on the peculiarities of the course of acute appendicitis in:

- A. * elderly patients
- B. females
- C. males
- D. pregnant
- E. children

99. Rovsing's sign is typical for:

- A. * acute appendicitis
- B. acute cholecystitis
- C. acute intestinal obstruction
- D. food poisoning

- E. acute pancreatitis
100. Rozdolsky's sign is typical for:
- A. * acute appendicitis
 - B. acute thrombophlebitis
 - C. pneumothorax
 - D. food poisoning
 - E. bleeding ulcer
101. Sitkovsky's sign is typical for:
- A. * acute appendicitis
 - B. acute cholecystitis
 - C. acute intestinal obstruction
 - D. food poisoning
 - E. acute pancreatitis
102. Strengthening of pain in right iliac region on the left side - is:
- A. * Sitkovsky's sign
 - B. Obrastsow's sign
 - C. Voskresensky's sign
 - D. Kocher-Volkovitch's sign
 - E. Bartomier-Mikhelson's sign
103. The absence of muscular tenderness is typical for:
- A. * Pelvic appendicitis
 - B. Retrocecal appendicitis
 - C. Phlegmonous appendicitis
 - D. Simple appendicitis
 - E. Left-side appendicitis appendicitis
104. The appendix ends its formation at the age of:
- A. * 7 years
 - B. 6 months
 - C. 1 year
 - D. 3 years
 - E. 3 months
105. The bailer form of appendix is characteristic for:
- A. * new-born
 - B. males
 - C. females
 - D. pregnant
 - E. elderly patients
106. The Bartomier's sign is typical for:
- A. * Simple appendicitis
 - B. Retrocecal appendicitis
 - C. Retroperitoneal appendicitis
 - D. Pelvic appendicitis
 - E. Left-side appendicitis
107. The Blumberg's sign is typical for:
- A. * Phlegmonous appendicitis
 - B. Simple appendicitis

- C. Retrocecal appendicitis
 - D. Retroperitoneal appendicitis
 - E. Pelvic appendicitis
108. The changes in clinical manifestation of acute appendicitis in pregnancy is characterized :
- A. * by the absence of signs of peritoneal irritation
 - B. by the presence of signs of peritoneal irritation
 - C. by the presence of expressed signs of peritoneal irritation
 - D. by displacement of the signs of peritoneal irritation
 - E. by the change of the character of signs of peritoneal irritation
109. The changes of clinical manifestations of acute appendicitis in pregnancy are caused by the displacement of appendix in relation to cecum:
- A. * upword
 - B. lateral
 - C. downword
 - D. medial
 - E. retroperitoneal
110. The changes of clinical manifestations of acute appendicitis in pregnancy are caused by:
- A. * distension of anterior abdominal wall by uterus
 - B. inflammation of uterus
 - C. irritation of anterior abdominal wall by uterus
 - D. compression of appendix by uterus
 - E. inflammation of the right ovarium
111. The changes of clinical manifestations of acute appendicitis in pregnancy are caused by:
- A. * absence of muscular tension of anterior abdominal wall
 - B. absence of tension of the uterus
 - C. presence of tension of the uterus
 - D. expressed muscular tension of anterior abdominal wall
 - E. presence of tension of peritoneum of anterior abdominal wall
112. The clinical manifestation of acute appendicitis does not relate to destructive changes in the appendix in:
- A. * elderly patients
 - B. children
 - C. females
 - D. males
 - E. pregnant
113. The clinical manifestation of acute appendicitis in pregnancy depends on:
- A. * the term of pregnancy
 - B. degree of inflammatory changes
 - C. the relation of appendix to peritoneum
 - D. the duration of appendicitis
 - E. the form of appendicitis
114. The clinical manifestation of appendicular infiltrate is:
- A. * swelling
 - B. the signs of peritoneal irritation
 - C. muscular tension
 - D. high temperature
 - E. leucocytosis

115. The clinical manifestations of acute appendicitis in pregnancy are characterised by the changes of:
- A. * localization of pain
 - B. severity of pain
 - C. irradiation of pain
 - D. duration of pain
 - E. character of pain
116. The clinical manifestations of acute appendicitis in the first trimester of the pregnancy are:
- A. * typical
 - B. atypical
 - C. expressed
 - D. unexpressed
 - E. absent
117. The clinical manifestations of acute appendicitis in the second trimester of the pregnancy are:
- A. * typical
 - B. atypical
 - C. expressed
 - D. unexpressed
 - E. absent
118. The clinical manifestations of acute appendicitis in the third trimester of the pregnancy are:
- A. * atypical
 - B. typical
 - C. expressed
 - D. unexpressed
 - E. absent
119. The conditions, which contribute to the formation of appendicular infiltrate include:
- A. * Phlegmonous changes of appendix
 - B. Chronic appendicitis
 - C. Meckel's diverticulum
 - D. Pylephlebitis
 - E. Perforation of appendix
120. The destructive changes in the appendix don't relate to the clinical manifestation of acute appendicitis in:
- A. * elderly patients
 - B. children
 - C. females
 - D. males
 - E. pregnant
121. The distinctive peculiarities of acute appendicitis in the second half of pregnancy are:
- A. * Weak express of pain syndrome, similar to the ligamentary tension of uterus
 - B. Absence of Volkovcha-Kocher's sign
 - C. Expressed signs of peritoneal irritation
 - D. The express local muscular tension in a right iliac area
 - E. Expressed of Obraztsov's sign
122. The Dunphy's sign is typical for:

- A. * Simple appendicitis
 - B. Retrocecal appendicitis
 - C. Retroperitoneal appendicitis
 - D. Pelvic appendicitis
 - E. Left-side appendicitis
123. The dysuria is typical for:
- A. * Pelvic appendicitis
 - B. Retrocecal appendicitis
 - C. Phlegmonous appendicitis
 - D. Simple appendicitis
 - E. Left-side appendicitis appendicitis
124. The expressed deviation of the differential leukocyte count to the left in acute appendicitis is characteristic for persons :
- A. * elderly patients
 - B. females
 - C. males
 - D. pregnant
 - E. children
125. The expressed pain in a right lumbar area is typical for:
- A. * Retrocecal appendicitis
 - B. Phlegmonous appendicitis
 - C. Simple appendicitis
 - D. Left-side appendicitis appendicitis
 - E. Pelvic appendicitis
126. The Gabay's sign is typical for:
- A. * Retrocecal appendicitis
 - B. Phlegmonous appendicitis
 - C. Simple appendicitis
 - D. Left-side appendicitis appendicitis
 - E. Pelvic appendicitis
127. The most frequent complications of appendicitis are:
- A. * infiltrate, abscess, pilephlebitis, peritonitis
 - B. infiltrate, abscess, thrombophlebitis, hepatitis
 - C. conglomerate, adhesions, cystitis, peritonitis
 - D. infiltrate, conglomerate, hepatitis
 - E. abscess, peritonitis, adhesions, phlebitis
128. The most informative for differentiation of appendicitis with a basal pleurisy is:
- A. * X-ray film
 - B. percussion
 - C. tomography
 - D. auscultation
 - E. bronchoscopy
129. The most informative for differentiation of appendicitis with an epigastric form of myocardial infarction are the changes in:
- A. * ECG
 - B. hemodynamic disturbances
 - C. expressed shortness of breath

- D. auscultation
 - E. tachycardia
130. The most informative for differentiation of appendicitis with food poisoning is:
- A. * frequent vomit
 - B. single vomit
 - C. nausea
 - D. increased peristalsis
 - E. slow peristalsis
131. The most informative for differentiation of appendicitis with gastric phlegmon is:
- A. * esophagogastroscopy
 - B. roentgenoscopy
 - C. palpation
 - D. laparocentesis
 - E. ultrasound examination
132. The most informative for differentiation of appendicitis with intercostal neuralgia is:
- A. * paravertebral blockade
 - B. laparoscopy
 - C. microlaparotomy
 - D. laparocentesis
 - E. peridural blockades
133. The most informative for differentiation of appendicitis with perforative ulcer of duodenum is:
- A. * absence of hepatic dullness
 - B. presence of hepatic dullness by percussion
 - C. absence of the splenic dullness
 - D. presence of a high tympanic sound by percussion
 - E. absence of the gastric dullness
134. The most informative for the differentiation of appendicitis with cholecystitis is:
- A. * ultrasound examination
 - B. X-ray film
 - C. anamnesis
 - D. laparocentesis
 - E. laparoscopy
135. The most informative for the differentiation of appendicitis with intestinal obstruction is:
- A. * X-ray film
 - B. ultrasound examination
 - C. blockade
 - D. laparotomy
 - E. laparoscopy
136. The most informative for the differentiation of appendicitis with pancreatitis is:
- A. * ultrasound examination
 - B. blockades
 - C. laparostomy
 - D. laparoscopy
 - E. X-ray film
137. The most informing method of instrumental diagnostics of acute appendicitis is:

- A. * tomography
 - B. esophagogastroscopy
 - C. colonoscopy
 - D. gastroscopy
 - E. contrasting roentgenoscopy
138. The most informing method of instrumental diagnostics of acute appendicitis is:
- A. * ultrasound examination
 - B. contrasting roentgenoscopy
 - C. gastroscopy
 - D. esophagogastroscopy
 - E. colonoscopy
139. The most prominent clinical sign of chronic appendicitis is:
- A. * pain by deep palpation
 - B. pain by percussion
 - C. pain by superficial palpation
 - D. skin hyperesthesia
 - E. pain by bimanual palpation
140. The omental hypoplasia influences on the peculiarities of the course of acute appendicitis in:
- A. * children
 - B. females
 - C. males
 - D. pregnant
 - E. elderly patients
141. The omental hypoplasia influences on the peculiarities of the course of acute appendicitis in:
- A. * children
 - B. females
 - C. males
 - D. pregnant
 - E. elderly patients
142. The pain all over the whole abdomen in acute appendicitis is characteristic for:
- A. * children
 - B. females
 - C. pregnant
 - D. males
 - E. elderly patients
143. The pain all over the whole abdomen in acute appendicitis is characteristic for:
- A. * children
 - B. females
 - C. pregnant
 - D. males
 - E. elderly patients
144. The painfulness of anterior rectal wall is typical for:
- A. * Pelvic appendicitis
 - B. Retrocecal appendicitis
 - C. Phlegmonous appendicitis

- D. Simple appendicitis
 - E. Left-side appendicitis appendicitis
145. The painfulness of the left iliac region is typical for:
- A. * Left-side appendicitis appendicitis
 - B. Pelvic appendicitis
 - C. Retrocecal appendicitis
 - D. Phlegmonous appendicitis
 - E. Simple appendicitis
146. The Pasternatsky's sign is typical for:
- A. * Retrocecal appendicitis
 - B. Phlegmonous appendicitis
 - C. Simple appendicitis
 - D. Left-side appendicitis appendicitis
 - E. Pelvic appendicitis
147. The peculiarities of the clinical course of appendicitis in children are caused:
- A. * by the bailed form of appendix
 - B. by the tubular form of appendix
 - C. by hypertrophy of appendix
 - D. by atrophy of appendix
 - E. by the spherical form of appendix
148. The peculiarities of the clinical course of appendicitis in children are caused:
- A. * by the bailed form of appendix
 - B. by the tubular form of appendix
 - C. by hypertrophy of appendix
 - D. by atrophy of appendix
 - E. by the spherical form of appendix
149. The pelvic appendicitis manifests by:
- A. * F. tenesmi
 - B. G. spasms
 - C. H. myalgia
150. paresis
- A. J. enuresis
151. The pelvic appendicitis manifests by:
- A. * diarrhea
 - B. vomiting
 - C. constipation
 - D. nausea
 - E. colicks
152. The pelvic appendicitis manifests by:
- A. * dysurination
 - B. dyspepsia
 - C. hyperthermia
 - D. hematuria
 - E. dystrophy
153. The psoas sign is typical for:
- A. * Retrocecal appendicitis

- B. Phlegmonous appendicitis
 - C. Simple appendicitis
 - D. Left-side appendicitis appendicitis
 - E. Pelvic appendicitis
154. The pulling rectal pain is typical for:
- A. * Pelvic appendicitis
 - B. Retrocecal appendicitis
 - C. Phlegmonous appendicitis
 - D. Simple appendicitis
 - E. Left-side appendicitis appendicitis
155. 154. The purulent inflammation of portal vein as the complication of acute appendicitis - is:
- A. * pilephlebitis
 - B. mesadenitis
 - C. tiplitis
 - D. thrombophlebitis
 - E. adnexitis
156. The rapid spread of inflammatory process in acute appendicitis is characteristic for:
- A. * children
 - B. females
 - C. males
 - D. pregnant
 - E. elderly patients
157. The rapid spread of inflammatory process in acute appendicitis is characteristic for:
- A. * children
 - B. females
 - C. males
 - D. pregnant
 - E. elderly patients
158. The removal of appendix from apex - is :
- A. * antegrade appendectomy
 - B. retrograde appendectomy
 - C. retrocecal appendectomy
 - D. antececal appendectomy
 - E. laparoscopic appendectomy
159. The removal of appendix from the base is:
- A. * Retrograde appendectomy
 - B. antegrade appendectomy
 - C. retrocecal appendectomy
 - D. antececal appendectomy
 - E. laparoscopic appendectomy
160. The Rovsing's sign is typical for:
- A. * Simple appendicitis
 - B. Retrocecal appendicitis
 - C. Retroperitoneal appendicitis
 - D. Pelvic appendicitis
 - E. Left-side appendicitis

161. The Rozdolsky's sign is typical for:
- A. * Phlegmonous appendicitis
 - B. Simple appendicitis
 - C. Retrocecal appendicitis
 - D. Retroperitoneal appendicitis
 - E. Pelvic appendicitis
162. The sign of gas migration is called:
- A. * Rovsing's sign
 - B. Kocher's sign
 - C. Sitkovsky's sign
 - D. Bartomier's sign
 - E. Dunphy's sign
163. The Sitkovsky's sign is typical for:
- A. * Simple appendicitis
 - B. Retrocecal appendicitis
 - C. Retroperitoneal appendicitis
 - D. Pelvic appendicitis
 - E. Left-side appendicitis
164. The tenesmi are typical for:
- A. * Pelvic appendicitis
 - B. Retrocecal appendicitis
 - C. Phlegmonous appendicitis
 - D. Simple appendicitis
 - E. Left-side appendicitis appendicitis
165. The undiagnosed destructive appendicitis complicated by:
- A. * infiltrate
 - B. fistula
 - C. adhesions
 - D. bleeding
 - E. colic
166. The Voskresenky's sign is typical for:
- A. * Phlegmonous appendicitis
 - B. Simple appendicitis
 - C. Retrocecal appendicitis
 - D. Retroperitoneal appendicitis
 - E. Pelvic appendicitis
167. The Yaure-Rozanov sign is typical for:
- A. * Retrocecal appendicitis
 - B. Phlegmonous appendicitis
 - C. Simple appendicitis
 - D. Left-side appendicitis appendicitis
 - E. Pelvic appendicitis
168. To the chronic secondary appendicitis belongs:
- A. * residual
 - B. catarrhal
 - C. empyema

- D. phlegmonous
 - E. gangrenous
169. Tumour with fluctuation are the main clinical manifestation of:
- A. * appendicular abscess
 - B. appendicular peritonitis
 - C. appendicular infiltrate
 - D. appendicular mesadenitis
 - E. appendicular typhlitis
170. Typical complications of the appendicitis are:
- A. * infiltrate, abscess, peritonitis, pilephlebitis
 - B. abscess, phlegmon, paraproctitis, pilephlebitis
 - C. infiltrate, gangrene, paraproctitis, pilephlebitis
 - D. abscess, phlegmon, peritonitis, pilephlebitis
 - E. infiltrate, abscess, osteomyelitis, pilephlebitis
171. Voskresenky's sign is typical for:
- A. * acute appendicitis
 - B. acute thrombophlebitis
 - C. pneumothorax
 - D. food poisoning
 - E. bleeding ulcer
172. What clinical picture is typical for appendicitis in children?
- A. * Clinic of destructive forms of appendicitis and intoxication
 - B. Abdominal distension
 - C. Absence of dyspeptic manifestation
 - D. Absence of muscular tenderness
 - E. Clinic of acute intestinal obstruction
173. What complication is typical for acute appendicitis?
- A. * Appendicular infiltrate
 - B. Appendicular bleeding
 - C. Acute intestinal obstruction
 - D. Appendicular-intestinal fistula
 - E. Malignization
174. What complication is typical for acute appendicitis?
- A. * Appendicular abscess
 - B. Appendicular bleeding
 - C. Acute intestinal obstruction
 - D. Appendicular-intestinal fistula
 - E. Malignization
175. What does the Bartomier-Mikhelson's sign mean?
- A. * The increase of pain intensity during the palpation of right iliac area when the patient lies on the left side.
 - B. Increased pain with coughing
 - C. Pain in right lower quadrant during palpation of left lower quadrant
 - D. Increase of pain in a right iliac area when the patient lies on the left side
 - E. Migration of pain to the right iliac area from epigastric
176. What does the Blumberg's sign mean?

- A. * The sharp increase of pain quick taking off the hand during palpation of anterior abdominal wall.
 - B. Increased pain with coughing
 - C. Pain in right lower quadrant during palpation of left lower quadrant
 - D. Increase of pain in a right iliac area when the patient lies on the left side
 - E. Migration of pain to the right iliac area from epigastric
177. What does the Dunphy's sign mean?
- A. * Increased pain with coughing
 - B. Pain in right lower quadrant during palpation of left lower quadrant
 - C. Increase of pain in a right iliac area when the patient lies on the left side
 - D. The increase of pain intensity during the palpation of right iliac area when the patient lies on the left side.
 - E. Migration of pain to the right iliac area from epigastric
178. What does the examination of infant children in acute appendicitis require to use?
- A. * Chloralhydrate enema
 - B. Contrast enema
 - C. Siphon enema
 - D. Cleaning enema
 - E. X-ray with barium swallow
179. What does the Gabay's sign mean?
- A. * Blumberg's sign in Petit triangle
 - B. Pain in right lower quadrant during palpation of left lower quadrant
 - C. Migration of pain to the right iliac area from epigastric
 - D. Tapping of lumbar region cause the pain
 - E. Increase of pain in a right iliac area when the patient lies on the left side
180. What does the Gabay's sign mean?
- A. * Blumberg's sign in Petit triangle
 - B. Increased pain with coughing
 - C. Pain in right lower quadrant during palpation of left lower quadrant
 - D. Increase of pain in a right iliac area when the patient lies on the left side
 - E. Migration of pain to the right iliac area from epigastric
181. What does the Kocher's sign mean?
- A. * Migration of pain to the right iliac area from epigastric
 - B. Pain in right lower quadrant during palpation of left lower quadrant
 - C. Increase of pain in a right iliac area when the patient lies on the left side
 - D. The increase of pain intensity during the palpation of right iliac area when the patient lies on the left side.
 - E. Increased pain with coughing
182. What does the Pasternatsky's sign mean?
- A. * Tapping of lumbar region cause the pain
 - B. Pain in right lower quadrant during palpation of left lower quadrant
 - C. Increase of pain in a right iliac area when the patient lies on the left side
 - D. Increased pain with coughing
 - E. Migration of pain to the right iliac area from epigastric
183. What does the psoas sign mean?
- A. * Pain on extension of right thigh
 - B. Increased pain with coughing

- C. Pain in right lower quadrant during palpation of left lower quadrant
 - D. Increase of pain in a right iliac area when the patient lies on the left side
 - E. Migration of pain to the right iliac area from epigastric
184. What does the psoas-sign mean?
- A. * Pain on extension of right thigh
 - B. Painfulness during palpation of Petit triangle
 - C. Migration of pain to the right iliac area from epigastric
 - D. Tapping of lumbar region cause the pain
 - E. Increase of pain in a right iliac area when the patient lies on the left side
185. What does the Rovsing's sign mean?
- A. * Pain in right lower quadrant during palpation of left lower quadrant
 - B. Increase of pain in a right iliac area when the patient lies on the left side
 - C. The increase of pain intensity during the palpation of right iliac area when the patient lies on the left side.
 - D. Increased pain with coughing
 - E. Migration of pain to the right iliac area from epigastric
186. What does the Rozdolsky's sign mean?
- A. * Painfulness in a right iliac area during percussion
 - B. Pain in right lower quadrant during palpation of left lower quadrant
 - C. Increase of pain in a right iliac area when the patient lies on the left side
 - D. Increased pain with coughing
 - E. Migration of pain to the right iliac area from epigastric
187. What does the Rozdolsky's sign mean?
- A. * Painfulness in a right iliac area during percussion.
 - B. Increased pain with coughing
 - C. Pain in right lower quadrant during palpation of left lower quadrant
 - D. Increase of pain in a right iliac area when the patient lies on the left side
 - E. Migration of pain to the right iliac area from epigastric
188. What does the Sitkovsky's sign mean?
- A. * Increase of pain in a right iliac area when the patient lies on the left side
 - B. Pain in right lower quadrant during palpation of left lower quadrant
 - C. The increase of pain intensity during the palpation of right iliac area when the patient lies on the left side.
 - D. Increased pain with coughing
 - E. Migration of pain to the right iliac area from epigastric
189. What does the Voskresenky's sign mean?
- A. * Increase of pain during quick sliding movements by the tips of fingers from epigastric to right iliac area
 - B. Pain in right lower quadrant during palpation of left lower quadrant
 - C. Increase of pain in a right iliac area when the patient lies on the left side
 - D. Increased pain with coughing
 - E. Migration of pain to the right iliac area from epigastric
190. What does the Voskresenky's sign mean?
- A. * The increase of pain during quick sliding movements by the tips of fingers from epigastric to right iliac area.
 - B. Increased pain with coughing
 - C. Pain in right lower quadrant during palpation of left lower quadrant

- D. Increase of pain in a right iliac area when the patient lies on the left side
 - E. Migration of pain to the right iliac area from epigastric
191. What does the Yaure-Rozanov sign mean?
- A. * Painfulness during palpation of Petit triangle
 - B. Pain in right lower quadrant during palpation of left lower quadrant
 - C. Migration of pain to the right iliac area from epigastric
 - D. Tapping of lumbar region cause the pain
 - E. Increase of pain in a right iliac area when the patient lies on the left side
192. What does the Yaure-Rozanov sign mean?
- A. * Painfulness during palpation of Petit triangle
 - B. Increased pain with coughing
 - C. Pain in right lower quadrant during palpation of left lower quadrant
 - D. Increase of pain in a right iliac area when the patient lies on the left side
 - E. Migration of pain to the right iliac area from epigastric
193. What dyspeptic manifestations are typical for acute appendicitis?
- A. * Single nausea and vomiting
 - B. Constant vomiting and nausea without any relief
 - C. Vomiting by bile without any relief
 - D. Absence of peristalsis
 - E. Constant diarrhea
194. What form of appendicitis the signs of peritoneal irritation are absent in?
- A. * chronic
 - B. calculous
 - C. perforative
 - D. appendicular infiltrate
 - E. appendicular abscess
195. What form of the appendicitis results in the developing of fibrosis of the appendix?
- A. * chronic
 - B. phlegmonous
 - C. catarrhal
 - D. gangrenous
 - E. perforative
196. What form of the appendicitis results in the obliteration of the appendix??
- A. * chronic
 - B. phlegmonous
 - C. catarrhal
 - D. gangrenous
 - E. perforative
197. What is the lethality in acute appendicitis caused by?
- A. * late hospitalization
 - B. tactical errors
 - C. concomitant diseases
 - D. technical errors during an operation
 - E. severity of disease
198. What is the medical tactic of the acute appendicitis in pregnant:
- A. * to operate

- B. to prescribe antibiotics
 - C. to prescribe conservative therapy
 - D. to observe
 - E. to interrupt pregnancy
199. What is the treatment of appendicular infiltrate?
- A. * Conservative treatment
 - B. Draining operation
 - C. Appendectomy
 - D. Hemicolectomy
 - E. Caecostomy
200. What manifestation is predominant for pelvic appendicitis?
- A. * Clinic of irritation of pelvic organs (dysuria, pulling rectal pain, tenesmi)
 - B. Clinic of acute abdomen
 - C. Clinic of retroperitoneal phlegmon
 - D. Clinic of acute intestinal obstruction
 - E. Clinic of acute pancreatitis
201. What manifestation is predominant for retroperitoneal appendicitis?
- A. * Clinic of retroperitoneal phlegmon
 - B. Clinic of acute abdomen
 - C. Dyspeptic syndrome
 - D. Clinic of acute intestinal obstruction
 - E. Clinic of acute pancreatitis
202. What manifestation is typical for pelvic appendicitis?
- A. * Absence of muscular tenderness
 - B. Clinic of retroperitoneal phlegmon
 - C. Clinic of acute intestinal obstruction
 - D. Clinic of acute abdomen
 - E. Clinic of acute pancreatitis
203. What objective manifestations are typical for acute appendicitis?
- A. * Muscular tension in a right iliac area
 - B. Abdominal distension
 - C. Absence of hepatic dullness
 - D. Absence of peristalsis
 - E. Rigidity of anterior abdominal wall
204. What objective manifestations are typical for retrocaecal appendicitis?
- A. * Pain and muscular rigidity in a right iliac area during palpation
 - B. Abdominal distension
 - C. Absence of hepatic dullness
 - D. Clinic of retroperitoneal phlegmon
 - E. Rigidity of anterior abdominal wall
205. What objective manifestations are typical for retrocaecal appendicitis?
- A. * Painfulness of anterior rectal wall and posterior vaginal vault
 - B. Abdominal distension
 - C. Absence of hepatic dullness
 - D. Clinic of retroperitoneal phlegmon
 - E. Rigidity of anterior abdominal wall

206. What sign is typical for phlegmonous appendicitis in contrast to simple appendicitis?
- A. * Blumberg's sign
 - B. Kocher's sign
 - C. Bartomier's sign
 - D. Sitkovsky's sign
 - E. Dunphy's sign
207. What sign is typical for phlegmonous appendicitis in contrast to simple appendicitis?
- A. * Voskresenky's sign
 - B. Sitkovsky's sign
 - C. Bartomier's sign
 - D. Kocher's sign
 - E. Dunphy's sign
208. What sign is typical for retrocaecal appendicitis in contrast to simple appendicitis?
- A. * Pasternatsky's sign
 - B. Kocher's sign
 - C. Bartomier's sign
 - D. Sitkovsky's sign
 - E. Dunphy's sign
209. What sign is typical for retrocaecal appendicitis in contrast to simple appendicitis?
- A. * Psoas sign
 - B. Sitkovsky's sign
 - C. Bartomier's sign
 - D. Kocher's sign
 - E. Dunphy's sign
210. What signs are typical for gangrenous appendicitis in contrast to simple appendicitis?
- A. * Signs of intoxication
 - B. Signs of gas migration
 - C. Retention of stool or single diarrhea
 - D. Muscular tension in a right iliac area
 - E. Single nausea and vomiting
211. What signs are typical for phlegmonous appendicitis in contrast to simple appendicitis?
- A. * Peritoneal signs
 - B. Signs of gas migration
 - C. Signs of pain migration
 - D. Muscular tension in a right iliac area
 - E. Nausea and vomiting
212. Where does the pain arise in the onset of acute appendicitis?
- A. * Epigastric region
 - B. Left iliac region
 - C. Right iliac region
 - D. Left subcostal region
 - E. Right lumbar region
213. Where does the pain irradiate in acute appendicitis?
- A. * Not irradiate
 - B. Lumbar region
 - C. Left iliac region
 - D. Right scapular

- E. Perineum
214. Where is the pain localized in acute appendicitis?
- A. * Right iliac region
 - B. Epigastric region
 - C. Left iliac region
 - D. Left subcostal region
 - E. Right lumbar region
215. Where is the pain localized in left-side appendicitis?
- A. * Left iliac region
 - B. Epigastric region
 - C. Right iliac region
 - D. Left subcostal region
 - E. Right lumbar region
216. Where is the pain localized in retrocaecal appendicitis?
- A. * Right lumbar region
 - B. Right iliac region
 - C. Epigastric region
 - D. Left iliac region
 - E. Left subcostal region
217. Which method of appendectomy is used in children before age 3?
- A. * ligation
 - B. amputation
 - C. retrograde
 - D. antegrade
 - E. laparoscopic
218. Who usually suffer from gangrenous appendicitis?
- A. * People of old age
 - B. Newborns
 - C. Children
 - D. Pregnant women
 - E. Young men
219. Yaure-Rozanov's sign is typical for:
- A. * acute appendicitis
 - B. acute thrombophlebitis
 - C. pneumothorax
 - D. food poisoning
 - E. bleeding ulcer
220. A patient 40 years old, suffered ulcerous diseases of stomach. Last 2 days the pain became less intensive, but weakness and dizziness were appear. Rose from a bed and lost consciousness. Pale. There are insignificant pains in epigastrium. It is
- A. Combination perforation with bleeding
 - B. Perforation
 - C. Malignization of ulcer
 - D. Stenosis of ulcer
 - E. * Gastroenteric bleeding
221. A sick on a background the stones in the common bile duct needs icterus:

- A. To the urgent operation
 - B. Conservative treatment
 - C. * To the urgent operation after preoperative preparation
 - D. Cannulations of the abdominal artery
 - E. Plasmapheresis
222. A veritable postcholecystectomy syndrome can be conditioned only
- A. Cicatrical stenosis of the common bile duct
 - B. The stone of the common bile duct not found during an operation
 - C. Stenosis of the large duodenal nipple
 - D. Duodenostasis
 - E. * Decline of tone of sphincter Oddi and expansion of the common bile duct after cholecystectomy
223. A veritable postcholecystectomy syndrome can be conditioned only:
- A. By cicatrical stenosis of the common bile duct
 - B. By the stone of the common bile duct not found during an operation
 - C. By stenosis of large duodenal nipple
 - D. Duodenostasis
 - E. * By the decline of tone the sphincter Oddie and expansion of the common bile duct after cholecystectomy
224. Absolute indication to operative treatment the ulcerous illness is
- A. heavy pain syndrome
 - B. * perforation of ulcer
 - C. relapses more than 2 one time per a year
 - D. ulcerous anamnesis more than 10 years
 - E. giant ulcers
225. Absolute indication to operative treatment the ulcerous illness is
- A. * voluminous bleeding
 - B. callous ulcers
 - C. relapses more than 2 one time per a year
 - D. ulcerous anamnesis more than 10 years
 - E. heavy pain syndrome
226. Absolute indication to operative treatment the ulcerous illness is
- A. ulcerous anamnesis more than 10 years
 - B. * bleeding what do not stopped with conservative
 - C. perforation ulcer in anamnesis
 - D. heavy pain syndrome
 - E. relapses more than 3 times per a year
227. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. ulcerous anamnesis more than 10 years
 - C. relapse ulcer after the resection of stomach
 - D. relapses more than 3 times per a year
 - E. * cicatrical-ulcerous stenosis of pylorus
228. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. * malignization ulcers
 - C. ulcerous anamnesis more than 10 years

- D. heavy pain syndrome, proof heartburn
 - E. relapse ulcer after vagotomy
229. Absolute sign of unstable hemostasis
- A. * profluvium blood from a vessel;
 - B. absence blood in a stomach and bulb of duodenum;
 - C. presence light blood and faltungs of blood in a stomach;
 - D. all answers are correct;
 - E. all answers are not correct
230. Acute cholecystitis usually begins with
- A. Increases the temperature
 - B. Appearance of vomiting
 - C. * Pains under a rib on the right
 - D. Disorders of chair
 - E. Weights are in an epigastric area
231. Acute cholecystitis usually begins with:
- A. Increases of temperatures
 - B. Appearances of vomiting
 - C. * Pains in right under rib space
 - D. Disorders of defecation
 - E. Weights in the epigastric area
232. Acute pancreatitis with a heavy flow treat in terms:
- A. Ambulatory
 - B. Permanent establishment
 - C. * Department of intensive therapy
 - D. All answers are faithful
 - E. A faithful answer is not present
233. After cholecystectomy drainage is more frequent than all used
- A. By Robson - Vishnevskiy
 - B. By Holsted - Pikovskiy
 - C. * To the couch of the gall-bladder and Winslow foramen
 - D. By Ker
 - E. Combination draining by Pikovskiy and Spasokukotskiy
234. After cholecystostomy drainage more frequent than all used:
- A. By Robson-Vishnevskiy
 - B. By Holsted-Pikovskiy
 - C. * By Spasokukotskiy
 - D. By Ker
 - E. Combination draining by Pikovskiy and Spasokukotskiy
235. After time of origin complications acute pancreatitis select:
- A. Premature and remote
 - B. Urgent and deferred
 - C. Primary and second
 - D. * Early and late
 - E. Any of variants faithful
236. After what operation at ulcerous illness the natural arc of meal is saved on a digestive tract

- A. Valter-Braun's gastroenterostomy
 - B. not saved after any operation
 - C. resection by Bilrot II
 - D. * resection by Bil'rot I
 - E. saved after all transferred operations
237. After what operation innervation of pyloric department of stomach is saved
- A. * selective vagotomy
 - B. barrel vagotomy
 - C. selective proximal vagotomy
 - D. at all transferred
 - E. not saved after all operations
238. All surgical interferences at the destructive forms of acute pancreatitis divide on:
- A. * Early, late, deferred operations
 - B. Primary, second, repeated operations
 - C. Invasion, not invasion operations
 - D. Complicated, operations are not complicated
 - E. Not divided
239. Among acute surgical diseases acute pancreatitis occupies:
- A. First place
 - B. * Third place
 - C. Fifth place
 - D. Second - third place
 - E. Most widespread
240. An intravenous cholecystography are indicated and informing at
- A. Gall-bladder is palpated
 - B. To the icterus
 - C. Peritonitis
 - D. * Calming down attack of the acute cholecystitis
 - E. Cholangitis
241. An intravenous cholecystography is indicated and informing:
- A. At presence of palpation the gall-bladder
 - B. At an icterus
 - C. At peritonitis
 - D. * At the calming down attack of the acute cholecystitis
 - E. At a cholangitis
242. As the first period flowing of acute pancreatitis is named:
- A. * Haemodynamic violations and pancreatic shock
 - B. To functional insufficiency of parenchymatous organs
 - C. Degenerative and festerings complications
 - D. All answers are faithful
 - E. A right answer is not present
243. As the second period flowing of acute pancreatitis is named:
- A. * Haemodynamic violations and pancreatic shock
 - B. To functional insufficiency of parenchymatous organs
 - C. Degenerative and festerings complications
 - D. All answers are faithful
 - E. A right answer is not present

244. As the third period flowing of acute pancreatitis is named:
- A. Haemodynamic violations and pancreatic shock
 - B. * To functional insufficiency of parenchymatous organs
 - C. Degenerative and festering complications
 - D. All answers are faithful
 - E. A right answer is not present
245. At a acute calculary cholecystitis can be used
- A. Extra operation
 - B. Urgent operation
 - C. Medicinal therapy is the planned operation in future
 - D. Only medicinal therapy
 - E. * All are right
246. At a acute calculary cholecystitis can be used:
- A. Extraordinary operation
 - B. Urgent operation
 - C. Conservative therapy is the planned operation in future
 - D. Only conservative therapy
 - E. * All transferred
247. At a frequent „fat” chair with disseminations of undigested meat and permanent thirst, it is foremost necessary to think about:
- A. * Chronic pancreatitis
 - B. Chronic duodenitis
 - C. Chronic hepatocholecystitis
 - D. Ulcerous diseases of duodenum
 - E. Hepatocirrhosis
248. At an acute and chronic cholecystitis application is contra-indicated
- A. Omnoponum
 - B. * Morphine hydrochloride
 - C. No-spa
 - D. Atropine sulfate
 - E. Spazmalgon
249. At beginning bleeding from an ulcer
- A. * pain diminishes
 - B. pain increases
 - C. there is knife-like pain
 - D. character of pain does not change
 - E. girdle pain
250. At bile-stones diseases cholecystectomy is indication
- A. * In all cases
 - B. At the latent form of disease
 - C. At the clinical signs of disease
 - D. Decline of ability to work
 - E. For patients more senior 55 years
251. At bleeding emergency operative interferences are executed
- A. * to 3 hours
 - B. to 1,5 hour

- C. to 6 hours
 - D. to 8 hours
 - E. 6 – 12 hours
252. At gangrenous cholecystitis is indication
- A. Deferred operation
 - B. Operation in default of effect from the conservative therapy
 - C. Conservative treatment
 - D. * Urgent operation
 - E. A decision-making depends on age of patient
253. At III stage blood loss at the bleeding ulcer the patient loses
- A. over 1000 ml blood
 - B. * over 2000 ml blood
 - C. over 500 ml blood
 - D. over 2500 ml blood
 - E. over 1500 ml blood
254. At III stage blood loss at the bleeding ulcer the patient loses
- A. more than 25 % blood volume
 - B. * more than 30 % blood volume
 - C. more than 20 % blood volume
 - D. more than 15 % blood volume
 - E. more than 35 % blood volume
255. At localization the stone in a cystic channel and absence infection the phenomenon is carried by the name
- A. Courvoisier's symptom
 - B. Acute cholecystitis
 - C. Hydrocholecystis
 - D. * Cyst of gall-bladder
 - E. All answers are not right
256. At pancreatitis abscesses and infected necroses execute such operations, except for:
- A. Opening of abscess with draining
 - B. Pancreaticnecrosekvestrektomy
 - C. Pancreaticsekvestrektomy
 - D. Pancreaticsekvestrektomy with laparostomy
 - E. * Total pancreatotomy
257. At the duodenum ulceroperation of choice is
- A. * resection by Bilrot I
 - B. resection by Bilrot II
 - C. resection of duodenum
 - D. selective proximal vagotomy
 - E. sewing up of ulcer
258. At the gastroenteric bleeding the middle degree of blood loss is diagnosed at next indexes
- A. Hb below 80 g/l
 - B. * Hb 80-100 g/l
 - C. red corpuscles below $2,5 \cdot 10^{12}/l$
 - D. red corpuscles of $3,5-4,0 \cdot 10^{12}/l$
 - E. Ht below 25%

259. At the III item of activity hemostasis and III stage blood loss from the I – III stage blood loss indicated
- A. * urgent operations (6 – 12 hours);
 - B. emergency operations (to 3 hours);
 - C. exigent operations (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
260. At the V item activity of hemostasis and at the recurrent bleeding of the I – III item of blood loss indicated
- A. * emergency operations (to 3 hours);
 - B. urgent operations (6 – 12 hours);
 - C. exigent (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
261. At transferring the stone from a gall-bladder in the common bile duct develops
- A. * Hepatic colic
 - B. Icterus
 - C. Festering cholangitis
 - D. Stenosis papillitis
 - E. Syndrome of Badd – Kiyary
262. At ulcerous illness can a bleeding source be
- A. artery;
 - B. veins;
 - C. shallow vessels and ulcers;
 - D. all answers are not correct.
 - E. * all answers are correct
263. At what disease pain of girdle character is characteristic:
- A. Gastric ulcers
 - B. Acute cholecystitis
 - C. Intestinal impassability
 - D. * Acute pancreatitis
 - E. Acute cystitis
264. At what pathology is absence pulsation of abdominal aorta
- A. * Acute cholecystitis
 - B. Acute pancreatitis
 - C. Perforated ulcer
 - D. Intestinal obstruction
 - E. Acute appendicitis
265. At what pathology is appearance cyanosis the sides of stomach:
- A. * Acute pancreatitis
 - B. Perforated ulcer
 - C. Acute cholecystitis
 - D. Intestinal obstruction
 - E. Acute appendicitis
266. At what pathology is appearance of sickliness in left costal-vertebral coal:
- A. * Acute pancreatitis
 - B. Acute cholecystitis

- C. Perforated ulcer
 - D. Intestinal obstruction
 - E. A right answer is not present
267. Basic method examination the patients with the uncomplicated cholecystitis
- A. Infusion cholegraphy
 - B. ERCP
 - C. * Sonography
 - D. Laparoskopy
 - E. Gastroduodenoscopy
268. Bergman's sign is characteristic for
- A. * bleeding ulcer
 - B. for cicatrical-ulcerous pylorostenosis
 - C. perforated ulcers
 - D. penetration ulcers
 - E. malignization ulcers
269. Berhstein's sign characteristic for
- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatrical-ulcerous pylorostenosis
270. Bile-stones diseases can cause everything, except for
- A. Cystic-duodenal fistula
 - B. Mechanical icterus
 - C. Acute cholecystitis
 - D. * Intra-abdominal bleeding
 - E. Cholangitis
271. Bile-stones diseases is dangerous all transferred, except for
- A. * Development the postnecrotic hepatocirrhosis
 - B. Cancer transformation of gall-bladder
 - C. Second pancreatitis
 - D. Development of destructive cholecystitis
 - E. Mechanical icterus
272. Bleeding ulcer, complicated blood loss III stage degrees, requires
- A. * blood and its components transfusions
 - B. transfusion of salt solutions
 - C. transfusion of colloid solutions
 - D. transfusion of salt and colloid solutions
 - E. infusion therapy does not need
273. Blood loss I stage characterized such indexes
- A. Ht 48-44, Hb 120
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 31-23, Hb 80
 - D. * Ht 38-32, Hb 100
 - E. Ht 44-40, Hb 110 /?
274. Blood loss II stage characterized

- A. * Ht 23 and below, Hb 50 and below
 - B. Ht 31-23, Hb 80
 - C. Ht 44-40, Hb 110
 - D. Ht 48-44, Hb 120
 - E. Ht 48-44, Hb 120
275. Blood loos III stage characterized a degree such indexes
- A. * Ht 31-23, Hb 80
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 38-32, Hb 100
 - D. Ht 44-40, Hb 110
 - E. Ht 48-44, Hb 120
276. Blumberg's sign is
- A. Sickliness at palpation of blind gut in position the patient on the left side
 - B. * Sickliness at the acute tearing away the palpation hand
 - C. Appearance or strengthening the pains in position on the left side
 - D. Percussion sickliness in a right iliac area
 - E. At pressing on a left arm in the left iliac area shove there causes a sickliness in a right iliac area
277. Bonde's sign at acute pancreatitis:
- A. * Swelling the stomach only in epigastrium
 - B. Cyanosis sides of stomach and trunk
 - C. Cyanosis skin of stomach
 - D. Ictericness round a belly-button
 - E. Cyanosis of hands
278. Can not stipulate a mechanical icterus
- A. Cancer the head of pancreas
 - B. * Stone of cystic channel
 - C. Chronic pancreatitis
 - D. Stone the general bilious channel
 - E. Tumour large duodenal papilla
279. Caused a remittent icterus is
- A. The wedged stone of terminal department of the common bile stone
 - B. The tumour of the common bile stone
 - C. The stone of cystic channel
 - D. * The valve stone of the common bile stone
 - E. Stricture of the common bile stone
280. Characteristic complication acute pancreatitis is:
- A. * Pancreonecrosis
 - B. Pylephlebitis
 - C. Hepatocirrhosis
 - D. Veritable pancreas cyst
 - E. Hepatitis
281. Characteristic complication the acute pancreatitis is:
- A. Paranephritis
 - B. Douglas's abscess
 - C. Pylephlebitis
 - D. Cyst of pancreas

- E. * Pancreonecrosis
282. Characteristic laboratory sign of the acute uncomplicated cholecystitis
- A. Diastasia
 - B. * Leukocytosis
 - C. Hypoglycemia
 - D. Glucosuria
 - E. Hyperbilirubinemia
283. Complication of choledocolitiasis
- A. Hydrocholecystis
 - B. Empyema of gall-bladder
 - C. * Icterus, cholangitis
 - D. Chronic active hepatitis
 - E. Perforate cholecystitis, peritonitis
284. Complications of acute cholecystitis
- A. Bleeding
 - B. * Empyema of gall-bladder
 - C. Syndrome of v. cava sup.
 - D. Artery-venous fistula
 - E. All answers are right
285. Complications of acute cholecystitis
- A. Bleeding
 - B. * Hepatic-renal insufficiency
 - C. Syndrome of v. cava sup.
 - D. Artery-venous fistula
 - E. All answers are right
286. Complications of acute cholecystitis
- A. Bleeding
 - B. * Mechanical icterus
 - C. Syndrome of v. cava sup.
 - D. Artery-venous fistula
 - E. All answers are right
287. Complications of acute cholecystitis
- A. Bleeding
 - B. * Hydrocholecystis
 - C. Syndrome of v. cava sup.
 - D. Artery-venous fistula
 - E. All answers are right
288. Complications of acute cholecystitis
- A. Bleeding
 - B. * Perforation of gall-bladder
 - C. Syndrome of v. cava sup.
 - D. Artery-venous fistula
 - E. All answers are right
289. Complications of acute cholecystitis
- A. Bleeding
 - B. * Peritonitis

- C. Syndrome of v. cava sup.
 - D. Artery-venous fistula
 - E. All answers are right
290. Complications of acute cholecystitis
- A. Bleeding
 - B. * Approximately cystic infiltration
 - C. Syndrome of v. cava sup.
 - D. Artery-venous fistula
 - E. All answers are right
291. Complications of acute cholecystitis
- A. Bleeding
 - B. * Approximately cystic abscess
 - C. Syndrome of v. cava sup.
 - D. Artery-venous fistula
 - E. All answers are right
292. Complications of the acute cholecystitis
- A. Bleeding
 - B. * Cholangitis
 - C. Syndrome v. cava sup.
 - D. Artery-venous fistula
 - E. All answers are right
293. Conservative treatment the acute pancreatitis includes:
- A. * Hunger
 - B. Povzner's diet №5
 - C. Povzner's diet №15
 - D. Moderation in a meal
 - E. Morning gymnastics
294. Courvoisier's symptom is
- A. Painless megascopic gall-bladder, patient is not yellow
 - B. Sickly megascopic gall-bladder, patient is not yellow
 - C. * Painless megascopic gall-bladder, patient is yellow
 - D. A gall-bladder don't palpaton
 - E. All answers are not right
295. De-Cerven's sing is characteristic for
- A. bleeding ulcer
 - B. * perforated ulcers
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatrical-ulcerous pylorostenosis
296. Diet at bleeding gastric and duodenum ulcers
- A. * Meulengracht's
 - B. 1 by Pevznerom
 - C. 5 by Pevznerom
 - D. 15 by Pevznerom
 - E. 7 by Pevznerom
297. Disappearance or diminishing the pain with beginning of bleeding from an ulcer is

- A. * Bergman's sign
 - B. Spazarskiy's sign
 - C. Mendel's sign
 - D. De Keven's sign
 - E. Eleker's sign
298. Duration the period of primary shock at a perforated ulcer
- A. * 3-6 hours
 - B. 6-12 hours
 - C. 1-3 hours
 - D. 12-24 hours
 - E. 24-36 hours
299. Early complications the acute pancreatitis is not:
- A. * Fistula of pancreas
 - B. Pancreatic shock
 - C. Collapse
 - D. Ferment peritonitis
 - E. Pancreatic delirious syndrome
300. Eleker's sign is characteristic for
- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorostenosis
301. ERCP apply at:
- A. Postcholecystectomy syndrome
 - B. Stenosing papillitis
 - C. * Stenosis the supraduodenal department of choledoch
 - D. Stricture the terminal department of choledoch
 - E. Mechanical icterus
302. Esophagogastroduodenoscopy can find out next changes in a stomach, except for
- A. tumours
 - B. ulcers
 - C. bleeding polypuses
 - D. erosions
 - E. * changes of evacuation function
303. Etiology of the acute cholecystitis:
- A. * Infection and stagnation of bile
 - B. Stagnation of bile
 - C. An infection in a gall-bladder
 - D. Duodenostasis
 - E. All answers are right
304. For a colic, caused a cholelithiasis, not characteristically
- A. A megalgia in a right side
 - B. Nausea
 - C. * Blumberg's sign in a right side
 - D. Ortner's sign
 - E. Merfi sign

305. For a mechanical icterus, conditioned the stones of the common bile duct , not characteristically
- Symptom of Kurvuazie
 - Increase the direct bilirubine of blood
 - Increase of alkaline phosphathase
 - A considerable increase level the transaminasis in plasma
 - * Absence the stercobiline in an excrement
306. For a patient 48 years clinical picture the acute phlegmon cholecystitis and phenomenon of the local peritonitis. Conservative treatment was conduct. Over 6 hours from a receipt great pains appeared in a stomach, death-damp, pulse is 120 in min, a stomach is tense and acute sickly in all departments, Blumberg's sing is positive. It is decided to make an operation
- * Cholecystectomy, revision the bilious channels, draining the abdominal region
 - Gastrotomy, sewing of acute ulcers
 - Cholecystectomy, draining and sanitization abdominal region
 - Sewing up of the perforated opening, sanitization and draining abdominal region
 - Cholecystectomy and gastrotomy
307. For an acute catarrhal cholecystitis not characteristic:
- Nausea
 - * Ker's sing
 - Merfi sing
 - Absence tension of muscles in right under rib space
 - Mussi sing
308. For an acute catarrhal cholecystitis not characteristically
- Nausea
 - Ker's sing
 - Merfi sing
 - * Tension the muscles in right underrib space
 - Symptom by Myussi
309. For an icterus on soil the stone ofcommon bile duct not characteristically:
- * Urobilinuria
 - Increase of alkaline phosphathase
 - A normal or lowered albumen in blood
 - Increase the bilirubine of blood
 - Normal or moderato enhanceable transaminase
310. For an icterus owing to stones of the common bile duct not characteristic
- * Urobilinuria
 - Increase of alkaline phosphatase
 - A normal or lowered albumen in blood
 - Increase bilirubine of blood
 - Normal or moderato increase of transaminase
311. For bleeding ulcer characteristic sign is
- * pain in an epigastrium;
 - knife-like pain;
 - signs irritation of peritoneum;
 - presence fresh blood in incandescence
 - melena;

312. For bleeding ulcer characteristically
- * melena
 - tension the muscles of front abdominal wall
 - Spazarskiy's sign
 - sickness the back vault of vagina
 - irradiation pain in a shoulder or shoulder-blade
313. For clarification the character icterus and reason of its origin don't used
- Computer tomography
 - * Peroral cholecystocholangiography
 - Throughskin transhepatic cholangiography
 - ERCPG
 - Sonography
314. For clarification character of the icterus and reason of its development is necessary to make:
- X-ray examination of the subhepatic space, infusion cholecystography, ERCP
 - Sonography, ERCP
 - Infusion cholecystography, ERCP
 - * Sonography, infusion cholecystography, ERCP
 - ERCP
315. For diagnostics of acute pancreatitis most informing is:
- * Sonography
 - CT
 - Cholangiography
 - Esophagogastroduodenoscopy
 - Colonoscopy
316. For motion of disease ulcerous illness of middle weight characteristically
- development of complications
 - * relapses 1-2 times per a year
 - 4 and anymore relapses on a year
 - 5 and more relapses are on a year
 - 3 and anymore relapses on a year
317. For pancreonecrosis characteristically is:
- * Rapid progress, strengthening pain, proof enteroplegia, growth haemodynamic violations
 - Rapid progress, diminishing pain, strengthening of моторики of intestine, growth haemodynamic violations
 - Slow progress, strengthening pain, phase of imaginary prosperity.
 - Abortive flow, toxemia, development shock.
 - Appearance light interval
318. For perforated ulcer characteristically
- * tension the muscles of front abdominal wall
 - melena
 - vomiting by coffee-grounds
 - high intestinal impassability
 - vomiting stagnant gastric maintenance
319. For pneumoperitoneum is characteristic symptom
- * Zhober's;
 - Khelatid's;

- C. Podlag's;
 - D. Vigats's;
 - E. Udin's.
320. For the abortive flowing characteristically:
- A. * A process limited to the acute edema with convalescence in 7-8 days
 - B. A process limited to tearing away of the pathologically changed gland
 - C. A process limited to tearing away of the pathologically unchanged gland
 - D. A disease completed so not attaining clinical displays
 - E. Changes from the side of organ are not present
321. For the clinic of acute cholangitis not characteristically
- A. High temperature
 - B. Pains in right under rib space
 - C. Icterus
 - D. Leucocytosis
 - E. * Unsteady liquid stool
322. For the clinic of acute obturation cholangitis not characteristically
- A. Icterus
 - B. Increase of temperature
 - C. * Diminishing sizes the liver
 - D. Leucocytosis
 - E. Increase the liver
323. For the exposure the stone of common bile duct without an icterus used more frequent than all
- A. * Sonography
 - B. Intravenous cholecystocholangiography
 - C. ERCPG
 - D. Peroral cholecystography
 - E. Low blood pressure duodenography
324. For the exposure the stone of the common bile duct not used:
- A. Sonography
 - B. Intravenous cholecystocholohgiography
 - C. ERPKHG
 - D. Transhepatic cholegraphy
 - E. * Low pressure duodenography
325. For the heavy flow of ulcerous illness characteristically
- A. 2 and anymore relapses on a year
 - B. * 3 and anymore relapses on a year
 - C. 4 and anymore relapses on a year
 - D. 5 and more relapses are on a year
 - E. 6 and more relapses are on a year
326. For the heavy flow of ulcerous illness characteristically
- A. * development of complications
 - B. seasonal exacerbation more not frequent 1-2 times per a year
 - C. 1-2 relapse on a year
 - D. liquid, but protracted exacerbation
 - E. exacerbation duration more than 10 days

327. For what pathology appearance of violet spots on the skin of person and trunk is characteristic:
- A. Perforated ulcer
 - B. Acute cholecystitis
 - C. * Acute pancreatitis
 - D. Intestinal obstruction
 - E. Acute appendicitis
328. From what department degestive tract developmentp more frequent than all the bleeding at the Mallory-Weiss syndrome
- A. gastric fundus
 - B. * cardial pert;
 - C. pyloric department;
 - D. from duodenal;
 - E. from a thick intestine
329. Giant ulcer is an ulcer measuring
- A. over 4,5 cm
 - B. * over 3 cm
 - C. over 4 cm
 - D. over 5 cm
 - E. over 3,5 cm
330. Hemobilia is
- A. * all answers are correct;
 - B. bleeding the bilious ways and liver;
 - C. bleeding the general bilious channel;
 - D. bloody clot in the big duodenal papilla;
 - E. all answers are not correct.
331. Holsted's sing at acute pancreatitis:
- A. Violet spots on face and trunk
 - B. Cyanosis sides of stomach and trunk
 - C. * Cyanosis skin of stomach
 - D. Icteritiousness round a belly-button
 - E. Cyanosys of hands
332. How many is the period of haemodynamic violations and pancreatic shock lasts:
- A. * 1-3 days
 - B. 3-7 days
 - C. More 7 days
 - D. 2 weeks
 - E. 2 hour
333. How many is the period of degenerative and festerings complications lasts:
- A. 1-3 days
 - B. 3-7 days
 - C. * More 7 days
 - D. 2 weeks
 - E. 2 hour
334. How many is the period of functional insufficiency of parenchymatous organs lasts:
- A. 1-3 days
 - B. * 3-7 days

- C. More 7 days
 - D. 2 weeks
 - E. 2 hour
335. How often does the pancreatitis department the general bilious channel pass through the head of pancreas?:
- A. * 80-90 %
 - B. 90-100 %
 - C. 75-85 %
 - D. 50-60 %
 - E. 40-50 %
336. In a gall-bladder stone formation don't promote
- A. Stagnation of bile in a bladder
 - B. Exchange violations
 - C. Inflammatory changes in a gall-bladder
 - D. Diskinetic of the bile excretive ways
 - E. * Violation secretion the pancreas
337. In obedience to classification complications of acute pancreatitis, after etiology and pathogeny, distinguish such complications, except for:
- A. Infectiously inflammatory
 - B. Enzymic
 - C. * Allergic
 - D. Mixed
 - E. Trombogemoragic
338. In the case of bile-stones diseases an urgent operation is indicated at
- A. Occlusion of cystic channel
 - B. Cholecystopancreatitis
 - C. * Perforate cholecystitis
 - D. The mechanical icterus
 - E. The hepatic colic
339. In what area of stomach practically never is not origin of ulcers, or it is extraordinarily rarely?
- A. small curvature of stomach;
 - B. back wall of stomach, nearer to small curvature;
 - C. large curvature of stomach
 - D. * cardiac part of stomach;
 - E. pylorus.
340. In what vein is a venous outflow carried out in from a stomach?
- A. * V. Portae;
 - B. V. odd;
 - C. V. pair;
 - D. V. overhead hollow;
 - E. V. lower hollow;
341. Indication to early operative interference at acute pancreatitis is:
- A. Acute oedematous pancreatitis
 - B. Acute pancreatolysis
 - C. * Acute traumatic pancreatitis at the „fresh” break the gland
 - D. Acute fatty pancreatitis

- E. A faithful answer is not present
342. Indication to early operative interference at acute pancreatitis is:
- A. Acute oedematous pancreatitis
 - B. Acute pancreatolysis
 - C. * Acute biliary pancreatitis
 - D. Acute fatty pancreatitis
 - E. Forming of pseudocyst
343. Indication to early operative interference at acute pancreatitis is:
- A. Acute pancreatolysis
 - B. Acute oedematous pancreatitis
 - C. * Progressive multiple organ failure what not added conservative therapy during 48-72 hours
 - D. Acute fatty pancreatitis
 - E. Forming of pseudocyst
344. Indications to special intraoperative examination bilious ways
- A. * A cholangitis, expansion of the common bile duct, plural shallow concrements in a gall-bladder, mechanical icterus in anamnesis
 - B. Cholangitis, expansion of the common bile duct, plural shallow concrements in a gall-bladder
 - C. Expansion of the common bile duct, icterus in the moment of operation, plural shallow concrements in a gall-bladder
 - D. Expansion of the common bile duct, mechanical icterus in anamnesis
 - E. All right
345. Indications to the special intraoperative examination the bilious ways
- A. Expansion the common bile duct, mechanical icterus in anamnesis
 - B. Expansion the common bile duct, icterus in the moment of operation, plural shallow concrements in a gall-bladder
 - C. * All right
 - D. A cholangitis, expansion the common bile duct, plural shallow concrements in a gall-bladder, mechanical icterus in anamnesis
 - E. Cholangitis, expansion the common bile duct, plural shallow concrements in a gall-bladder
346. Intraoperative cholangiographic is not absolutely indicated at
- A. Shallow stone in the common bile duct
 - B. Suspicion on the cancer the large duodenal nipple
 - C. Expansion of the common bile duct
 - D. To the mechanical icterus in anamnesis
 - E. * Switched-off gall-bladder
347. Intraoperative cholangiography at cholecystectomy used for
- A. Exposures of cholangitis
 - B. Researches of peristalsis of the general bilious channel
 - C. Researches the tone of sphincter Oddi
 - D. * Retrograde filling of intrahepatic bilious channels
 - E. Exceptions the concrements in channels
348. Intraoperative cholangiography is absolutely indication at everything, except for:
- A. Presences of shallow stone are in the common bile duct
 - B. Suspicion on the cancer of the large duodenal nipple

- C. Expansions the common bile duct
 - D. Mechanical icterus in anamnesis
 - E. * Switched-off gall-bladder
349. Intraoperative cholangiography at cholecystectomy used for
- A. Researches of peristalsis the general bilious channel
 - B. Retrograde filling of intrahepatic bilious channels
 - C. Researches tone the sphincter Oddi
 - D. * Exceptions concrements in channels
 - E. Exposures cholangitis
350. Intraoperative cholangiography is not indication at
- A. * Finding concrements in the common bile duct at palpation
 - B. Cancer the head of pancreas
 - C. The icterus in anamnesis
 - D. Expansion of common bile duct
 - E. The icterus during an operation
351. Kerte's sign at acute pancreatitis:
- A. Absence pulsation the abdominal aorta
 - B. Sickliness in left costal-vertebral coal
 - C. * Sickliness and proof tension the muscles in an epigastrium with passing to left subcostal area
 - D. Ictericness round a belly-button
 - E. Skin hyperesthesia in projection the gland
352. Kulen's sign at acute pancreatitis:
- A. Violet spots on face and trunk
 - B. Cyanosis sides of stomach and trunk
 - C. Cyanosis skin of stomach
 - D. * Ictericness round a belly-button
 - E. Cyanosis of hands
353. Kurvazie symptoms is not characteristic for
- A. * Acute calculary cholecystitis
 - B. Tumor the head of pancreas
 - C. The pancreatitis
 - D. Tumours large duodenal nipple
 - E. Tumours common bile duct
354. Large ulcer is an ulcer measuring
- A. 1-4 cm
 - B. 1-3 cm
 - C. 3-5 cm
 - D. 2- 6 cm
 - E. * 2-3 cm
355. Little ulcer it is an ulcer measuring
- A. * to 0,5 cm
 - B. 0,5-1 cm
 - C. to 1,0 cm
 - D. 3 to 1,5 cm
 - E. 0,5-1,5 cm

356. Meets the most frequent localization bleeding the digestive tract is
- gullet;
 - stomach;
 - rectum;
 - * duodenum;
 - colon
357. Megascopic sickly gall-bladder, positive Ortner's sign, Obraztsov's sign, Merfi sign, Ker's sign more frequent meet at
- * Acute cholecystitis
 - The hydrocholecystitis
 - Syndrom by Kurvuaz'e
 - Hepatitis
 - Panerkatitis
358. Melena is
- black designed chair
 - * black liquid tarry chair
 - a discoloured liquid excrement
 - foamy stinking emptying of black
 - an excrement designed veined blood
359. Melena is a characteristic sign
- * bleeding ulcer
 - for cicatrical-ulcerous pylorus stenosis
 - perforeted ulcers
 - penetration ulcers
 - malignization ulcers
360. Method intraoperative diagnostics the pathology of bilious ways
- Intravenous cholegraphy
 - * Choledochoscopy
 - Selective celiacography
 - Peroral cholecystography
 - All answers are right
361. Mayo-Robson's sign at acute pancreatitis:
- Absence pulsation the abdominal aorta
 - * Sickliness in left costal-vertebral coal
 - Sickliness and proof tension the muscles in an epigastrium with passing to left subcostal area
 - Icteritiousness round a belly-button
 - Skin hyperesthesia in projection the gland
362. Mondor's sign at acute pancreatitis:
- * Violet spots on face and trunk
 - Cyanosis sides of stomach and trunk
 - Cyanosis skin of stomach
 - Icteritiousness round a belly-button
 - Cyanosys of hands
363. Most informing method at a bleeding ulcer
- survey sciagraphy the organs of abdominal region
 - * EFGDS

- C. sciagraphy the stomach with contrasting
 - D. Sonography
 - E. Laparoskopy
364. 145. Most widespread laparoscopic operation at bile-stone illness:
- A. Cholecystectomy with revision the bilious ways
 - B. Ideal cholecysectomy
 - C. * Choledoholitotomy
 - D. Cholecystectomy
 - E. All answers are right
365. Name classic complications of ulcerous illness
- A. bleeding, pylorostenosis, second pancreatitis, malignization, perforation
 - B. * perforation, penetration, bleeding, pylorostenosis, malignization
 - C. malignization, pylorostenosis, penetration, anaemia, perforation
 - D. bleeding, perforation, second pancreatitis, anaemia, malignization
 - E. perforation, peritonitis, pancreatitis, bleeding, penetration
366. Name most frequent complication after ERDPH:
- A. * Pancreatitis
 - B. Cholangitis
 - C. Pancreatic sepsis
 - D. Reactive cholecystitis
 - E. Obstructing papillitis
367. Name principal reason the acute pancreatitis:
- A. Trauma the pancreas
 - B. * Bile-stone diseases
 - C. Alimentary factor
 - D. Chronic alcoholic pancreatitis
 - E. Cardiospasm
368. Name the optimum lines the operative interference concerning a acute pancreatitis after the beginning of disease:
- A. 7-8 days
 - B. 1-3 days
 - C. 1-5 days
 - D. 3-5 days
 - E. * Surgical treatment is not indicate
369. Name the optimum volume of operation at acute biliary pancreatitis:
- A. Deleting exsudate from an abdominal region
 - B. Decapsulation pancreas
 - C. Pancreatectomy
 - D. * Sanitization and draining the bilious ways
 - E. Draining the chanel of pancreas
370. Normal indexes the billirubin of blood:
- A. 0,10-0,68 mcmol/l
 - B. * 8,55-20,52 mcmol/l
 - C. 2,50-8,33 mcmol/l
 - D. 3,64-6,76 mcmol/l
 - E. 7,62-12,88 mcmol/l

371. Normal width of the common bile duct
- A. To 0,4 cm
 - B. * 0,5-0,7 cm
 - C. 0,8-1,3 cm
 - D. 1,4-2,0 cm
 - E. Over 2,0 cm
372. On a background choledocholithiasis needs a sick icterus
- A. To the urgent operation
 - B. Medicinal treatment
 - C. * To the urgent operation after preoperative preparation
 - D. Cannulations of the abdominal artery
 - E. Plazmopheresis
373. Operating access at operations on a stomach
- A. * Upper-middle laparotomy
 - B. Lower-middle laparotomy
 - C. Pararectum access
 - D. Volokovich-Dyakonov's access
 - E. Pfanenhtil's access
374. pathognomonic symptom at acute pancreatitis is:
- A. Pasternatskiy's sing
 - B. * Kulen's sing
 - C. Ker's sing
 - D. Lenander's sing
 - E. Roving's sing
375. Patient which the gastroenteric bleeding in house is necessary
- A. * To send a patient in surgical permanent establishment
 - B. To appoint rest, enter Cacl, vicasol
 - C. To wash a stomach, appoint a cold, rest of supervision
 - D. To send a patient in a therapeutic gastroenterology separation
 - E. A right answer absents
376. Patient with a gangrenous cholecystitis is indicating:
- A. * Urgent operation
 - B. Operation at default of effect from conservative therapy
 - C. Conservative treatment
 - D. Deferred operation
 - E. A decision-making depends on age of patient
377. Radical operation at a bleeding gastric ulcer and duodenum consists in
- A. sewing vessels on a draught;
 - B. * vagotomy or resection the stomach;
 - C. sewing vessels in an ulcer;
 - D. gastroenteroanastomosis;
 - E. all answers are faithful
378. Relative absolute indication to operative treatment ulcerous illness is
- A. * penetration of ulcer
 - B. ulcerous anamnesis more than 15 years
 - C. malignization ulcers
 - D. perforation of ulcer

- E. relapses more than 3 times per a year
379. Resection of stomach by Bilrot II belongs to
- A. * radical operation
 - B. palliative operation
 - C. draining operations
 - D. organ protect operation
 - E. does not belong to any group
380. Selective proximal vagotomy belongs to
- A. palliative
 - B. draining
 - C. * organ protect operation
 - D. resection
 - E. does not belong to any group
381. Signs of stable hemostasis
- A. * absence blood in a stomach and duodenum bulb;
 - B. presence the light blood and faltungs of blood in a stomach;
 - C. profluvium blood from a vessel;
 - D. all answers correct;
 - E. all answers are not correct
382. Signs of unstable hemostasis
- A. * the pulsation of vessel is determined;
 - B. the bottom ulcer is covered a fibrin;
 - C. profluvium blood from a vessel;
 - D. all answers are correct;
 - E. all answers are not correct.
383. Specify the optimum volume operation at acute biliar pancreatitis:
- A. Deleting exsudate from abdominal region
 - B. Decapsulation pancreas
 - C. Pancreatectomy
 - D. * Sanitization and draining bilious ways
 - E. Draining pancreas channel
384. Stone formation in a gall-bladder promote
- A. Infection, stagnation of bile, exchange violations, inflammatory processes in a bubble, constitution, enhanceable amount of bilious acids
 - B. * An infection, stagnation of bile, exchange violations, inflammatory processes in a bubble, sex, constitution
 - C. Stagnation of bile, inflammatory processes in a bubble, inflammatory processes in a bubble, half, enhanceable amount of bilious acids
 - D. An infection, stagnation of bile, exchange violations, inflammatory processes in a bubble, enhanceable amount of bilious acids
 - E. All answers correct
385. Stoneformation in a gall-bladder promote:
- A. * An infection, stagnation of bile, exchange violations, inflammatory processes in a bubble, sex, constitution
 - B. Infection, stagnation of bile, exchange violations, inflammatory processes in a bubble, constitution, raised amount of bilious acids

- C. Stagnation of bile, inflammatory processes in a bubble, inflammatory processes in a bubble, sex, raised amount of bilious acids
 - D. An infection, stagnation of bile, exchange violations, inflammatory processes in a bubble, raised amount of bilious acids
 - E. All answers correct
386. Symptoms perforation the gall-bladder are
- A. * Strengthening of pains, appearance Blumberg's sign on all stomach, irradiation the pain in a right shoulder
 - B. Megascopic sickly gall-bladder
 - C. Positive Ortner's sign
 - D. Positive Obraztsov's sign
 - E. All answers correct
387. The attack of hepatic (bilious) colic arises up:
- A. * Suddenly, acutely
 - B. After a initial period
 - C. Gradually, gradually
 - D. After the protracted starvation
 - E. After supercooling
388. The attack of hepatic (bilious) colic development
- A. * Suddenly, acutely
 - B. After a initial period
 - C. Gradually, gradually
 - D. After the protracted starvation
 - E. After supercooling
389. The characteristic laboratory sign of the acute uncomplicated cholecystitis is:
- A. Diastasia
 - B. * Leucocytosis
 - C. Hypoglycemia
 - D. Glucosuria
 - E. Hyperbilirubinemia
390. The Courvoisier's symptom is not observed at a cancer
- A. Heads of pancreas
 - B. Supraduodenal part of the common bile stone
 - C. Retroduodenal part of general bilious channel
 - D. Large duodenal papilla
 - E. * Gall-bladder
391. The index litogenic bile is determined correlation
- A. Cholesterol, bilirubine and lecithin
 - B. Billirubine, bilious acids and lecithin
 - C. Cholesterol, bilious acids and bilirubine
 - D. * Cholesterol, bilious acids and lecithin
 - E. Billirubine and lecithin
392. The laboratory signs of total pancreonecrosis is:
- A. Growth glucose concentration
 - B. Diminishing maintenance fibrinogenum
 - C. * Growth activity diastase
 - D. Diminishing activity diastase

- E. Growth index AST
393. The leading clinical symptoms the acute pancreatitis is:
- A. * Stomach-ache
 - B. Vomiting by „coffee-grounds”
 - C. Disuria
 - D. Febrile temperature of body
 - E. Lock
394. The liquid painted a bile in an abdominal region is not observed at
- A. * Break pus hydatidoma
 - B. To the protracted mechanical icterus
 - C. Spontaneous bilious peritonitis
 - D. Perforations of gall-bladder
 - E. Perforations the ulcer of duodenum
395. The liquid painted a bile in an abdominal region is not observed at
- A. Perforations the ulcer of duodenum
 - B. Perforations the gall-bladder
 - C. To the protracted mechanical icterus
 - D. * Break the pus hydatidoma
 - E. Spontaneous bilious peritonitis
396. The nosotropic mechanisms bleedingness at ulcerous illness is
- A. * all answers are correct.
 - B. permanent hyperemia all system of stomach
 - C. different degree dystrophy of superficial layers the mucus shell
 - D. accumulation the central mucopolysaccharides
 - E. hypoplastic, dystrophic processes
397. The patients with a gangrenous cholecystitis is indication
- A. Conservative treatment
 - B. Deferred operation
 - C. A decision-making depends on age of patient
 - D. Operation at default of effect from medicinal therapy
 - E. * Urgent operation
398. The secretory function stomach is carried out the next membrane of stomach
- A. * mucous membrane
 - B. internal muscular layer
 - C. serosal
 - D. mucous submembrane
 - E. external layer
399. The special examination the extrahepatic bilious ways is absolutely indicated at
- A. Suspicion on stenosis of large duodenal papilla, expansion the common bile duct, mechanical icterus in the moment of operation
 - B. Suspicion on stenosis of large duodenal papilla, expansion the common bile duct, to the mechanical icterus in anamnesis, mechanical icterus in the moment of operation
 - C. Expansion the common bile duct, mechanical icterus in the moment of operation
 - D. Shallow stone in the common bile duct, suspicion on stenosis of large duodenal papilla, expansion the common bile duct, mechanical icterus in the moment of operation
 - E. * All right

400. The special research extrahepatic bilious ways is absolutely indicated at:
- A. Shallow stone in common bile duct, suspicion on stenosis the large duodenal papilla, expansion of the common bile duct, mechanical icterus in the moment of operation
 - B. Suspicion on stenosis of large duodenal papilla, expansion of the common bile duct, mechanical icterus in the moment of operation
 - C. At expansion of the common bile duct
 - D. * All right
 - E. All not right
401. To absolute indication to operative interference at ulcerous illness does not belong
- A. * scary-ulcerous stenosis
 - B. perforation of ulcer
 - C. profuse bleeding
 - D. diameter ulcer a more than 3 cm
 - E. bleeding what does not stopped with conservative
402. To complications of the acute calculary cholecystitis does not attribute:
- A. * Phlebeurysm gullet
 - B. Mechanical icterus
 - C. Cholangitis
 - D. Subhepatic abscess
 - E. Peritonitis
403. To complications of the acute stone cholecystitis does not attribute
- A. * Varicose widening the vein of gullet
 - B. Mechanical icterus
 - C. Cholangitis
 - D. Under hepatic abscess
 - E. Peritonitis
404. To early complications acute pancreatitis attribute:
- A. Shock
 - B. Acute hepatic-kidney insufficiency
 - C. Poured out peritonitis
 - D. Icterus
 - E. * All answers are faithful
405. To the gastric – intestinal bleeding of un ulcerous etiology belong
- A. * Mallory-Weiss syndrome;
 - B. hemorrhagic erosive gastritis;
 - C. diseases by Randyu – Oslera – Vebera;
 - D. Menetrie's sing;
 - E. all answers are correct.
406. To the intraoperative methods research the extrahepatic bilious ways does not pertain
- A. Palpation of the common bile duct
 - B. Choledochoscopy
 - C. Intraoperative cholangiography
 - D. Sounding of the common bile duct
 - E. * Intravenous cholangiography
407. To the intraoperative methods of research the extrahepatic bilious ways all behaves, except for:

- A. Palpation of the common bile duct
 - B. Choledochoscopy
 - C. Intraoperative cholangiography
 - D. Soundings of the common bile duct
 - E. * Intravenous holangiography
408. Turner's sign at acute pancreatitis:
- A. Violet spots on face and trunk
 - B. * Cyanosis sides of stomach and trunk
 - C. Cyanosis skin of stomach
 - D. Ictericness round a belly-button
 - E. Cyanosis of hands
409. Udin's sign at a perforated ulcer is
- A. * feeling at palpation shove the gases which penetrate through the perforated opening
 - B. dulling perforated sound in the lateral departments of stomach
 - C. disappearance of hepatic dullness
 - D. irradiation pain in a shoulder or shoulder-blade
 - E. sickliness the back vault of vagina
410. Vomiting coffee-grounds is a characteristic sign
- A. * bleeding ulcer
 - B. penetrative ulcers
 - C. perforated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorus stenosis
411. Vomiting what arose up in 4-6 hours after eating characteristic for
- A. chronic alcoholic gastritis
 - B. cancer and ulcers of cardia
 - C. * pylorus ulcers
 - D. achalasia of gullet
 - E. ulcer and cancer the body of stomach
412. Voskresenskiy's sign at acute pancreatitis:
- A. * Absence pulsation the abdominal aorta
 - B. Sickliness in left costal-vertebral coal
 - C. Sickliness and proof tension the muscles in an epigastrium with passing to left subcostal area
 - D. Ictericness round a belly-button
 - E. Skin hyperesthesia in projection the gland
413. What nosotropic conditionality Voskresenskiy's sign at acute pancreatitis:
- A. * Inflammatory edema of pancreas
 - B. Reflex paresis of colon
 - C. Thrombosis of abdominal aorta
 - D. Embolism of abdominal aorta
 - E. Development of peritonitis
414. What a clinical flow can be at acute pancreatitis:
- A. Easy, middle, heavy
 - B. Acute, chronic
 - C. * Abortive, making progress
 - D. Edema, necrosis

- E. Any variant
415. What basic method the treatment of acute pancreatitis is:
A. Surgical
B. * Conservative
C. Homoeopathic
D. Physical therapy
E. A right answer is not present
416. What cages of pancreas are make glucagon:
A. клетки
B. клетки
C. -клетки
D. None of cages
E. D-клетки
417. What cages of pancreas are make insulin:
A. клетки
B. клетки
C. -клетки
D. None of cages
E. D-клетки
418. What colouring of chair is most characteristic for bleeding from the ulcer of stomach and duodwnum?
A. * Tarry excrement
B. Presence on the formed excrement of strokes of red blood
C. Littlechanged blood in an excrement
D. Excrement of the raspberry colouring with the admixtures of mucus
E. Acholic excrement
419. What complication the ulcerous illness of stomach is most characteristically for the patients of elderly and senile age
A. perforation
B. perforation + bleeding
C. pylorus stenosis
D. malignization + penetration
E. * bleeding
420. What complications at a acute pancreatitis is behave to early:
A. * Peritonitis
B. Phlegmon retroperitoneum space
C. Formation of pseudocysts
D. Development of saccharine diabetes
E. Intestinal impassability
421. What complications at a acute pancreatitis is behave to late:
A. Peritonitis
B. * Phlegmon retroperitoneum space
C. Formation of pseudocysts
D. Development of saccharine diabetes
E. Intestinal impassability
422. What external signs are characteristic for the profuse bleeding from a gastric ulcer?

- A. Vomiting by the littlechanged blood, excrement of the raspberry colouring
 - B. * Vomiting by the littlechanged blood, tarry darkly-cherry chair
 - C. Vomiting by a complete mouth by dark blood with clots, black formed excrement
 - D. Vomiting on the type of "coffee-grounds", presence on the formed incandescence of strokes of red blood
 - E. Tarry darkly-cherry chair
423. What from operations does not execute at surgical treatment complicated acute pancreatitis:
- A. Through draining the stuffing-box bag
 - B. Abdominisation the pancreas
 - C. Omentopankreatopeksiy
 - D. Left-side resection of gland
 - E. * Pancreatojejunostomy
424. What from preparations has the expressed bacteriostatic action on Helicobacter pyloris
- A. * trichopol
 - B. Liciviroton
 - C. oxiferiskorbon
 - D. atropine
 - E. pirinzsipin
425. What from the transferred operations does not belong to organ protective
- A. trunk vagotomy
 - B. * resection by Bilrot II
 - C. selective vagotomy
 - D. selective proximal vagotomy
 - E. the all transferred does not belong
426. What from the transferred operations on the stomach organ protective is
- A. * selective proximal vagotomy
 - B. resection by Bilrot I
 - C. resection by Bilrot II
 - D. gastrectomy
 - E. all are transferred
427. What hormone of pancreas has influences on metabolism glucose:
- A. * Insulin
 - B. Vasopressin
 - C. Adrenalin
 - D. Somatotropin
 - E. Tiroksin
428. What hormone of pancreas has influences on the exchange of fats:
- A. Insulin
 - B. Glyukagon
 - C. * Lipocainu
 - D. Adrenalin
 - E. Somatotropin
429. What hormones undertake the protective operating on the mucous membrane of stomach, except for
- A. * ACTH
 - B. epidermal factor of growth
 - C. prostaglandin E

- D. estrogens
 - E. STH
430. What is blood supply the body and tail pancreas:
- A. * Splenic artery
 - B. A.gastroduodenalis
 - C. A.gastrica sinistra
 - D. A.cystica
 - E. Variously
431. What is condition hematomesis at acute pancreatitis:
- A. Presence concomitant gastric ulcer
 - B. Presence concomitant gastritis
 - C. * Formation erosions in a stomach
 - D. Violation of microcirculation
 - E. Enzymes in blood
432. What is necrectomy:
- A. Delete the necrotic area within the limits of nonviable fabrics
 - B. * Delete the necrotic area within the limits of healthy fabrics
 - C. Delete part of organ with his transversal cutting within the limits of the changed fabrics
 - D. Total delete of organ
 - E. There is not a faithful answer
433. What is pancreas located in relation to a peritoneum:
- A. * Retroperitoneal
 - B. Mesoperitoneal
 - C. Intraperitoneal
 - D. All answers are incorrect
 - E. Variously
434. What is pancreatectomy:
- A. Delete the necrotic area within the limits of nonviable fabrics
 - B. Delete the necrotic area within the limits of healthy fabrics
 - C. Delete part of organ with his transversal cutting within the limits of the changed fabrics
 - D. * Total delete of organ
 - E. There is not a faithful answer
435. What is resection the pancreas:
- A. Delete the necrotic area within the limits of nonviable fabrics
 - B. Delete the necrotic area within the limits of healthy fabrics
 - C. * Delete part of organ with his transversal cutting within the limits of the changed fabrics
 - D. Total delete of organ
 - E. There is not a faithful answer
436. What is sequestrotomy:
- A. * Delete the necrotic area within the limits of nonviable fabrics
 - B. Delete the necrotic area within the limits of healthy fabrics
 - C. Delete part of organ with his transversal cutting within the limits of the changed fabrics
 - D. Total delete of organ

- E. There is not a faithful answer
437. What level diastase answers a acute pancreatitis:
A. 100-160
B. 200-500
C. * 600-1000
D. 1000-1500
E. 10-20
438. What level diastase answers a chronic pancreatitis:
A. * 200-500
B. 100-160
C. 600-1000
D. 1000-1500
E. 10-20
439. What level diastase answers pancreonecrosis:
A. 600-1000
B. 200-500
C. 100-160
D. * 1000-1500
E. 10-20
440. What localization of ulcer is most characteristic for the patients of elderly and senile age
A. * cardial department of stomach
B. overhead third of gullet
C. lower third of gullet
D. bulb of duodewnum
E. small curvature
441. What method diagnostics hte ulcerous illness most informing
A. * esophagogastroduodenoscopy
B. analysis of excrement on the hidden blood
C. X-ray
D. global analysis of blood
E. research of gastric secretion
442. What method is it orientation possible to define the volume of hemorrhage on at the acute gastroenteric bleeding?
A. On maintenance red corpuscles, haemoglobin, Ht, thrombocytes
B. On blood volume
C. * On an arteriotony, pulse, state of patient
D. On a globular volume
E. On the level of thrombocytes
443. What most effective blocker secretion of pancreas at acute pancreatitis:
A. Cyanocobalamin
B. Ubretid
C. Arginine
D. * Sandostatin
E. Benzogeksoniy
444. What most effective treatment the formed uncomplicated cyst is:
A. External draining the cyst

- B. Marsupialization
 - C. Resection the cyst within the limits of the unchanged gland
 - D. * Cysticenterostomy
 - E. Cystogastrostomy
445. What most effective treatment the unformed complicated cyst is:
- A. Conservative treatment
 - B. * External draining cyst
 - C. Resection cyst within the limits of the unchanged gland
 - D. Cysticenterostomy
 - E. Cystogastrostomy
446. What most effective treatment the unformed uncomplicated cyst is:
- A. * Conservative treatment
 - B. External draining cyst
 - C. Resection cyst within the limits of the unchanged gland
 - D. Cysticenterostomy
 - E. Cystogastrostomy
447. What most optimum resort is which used for pathology the pancreas:
- A. Pyatigorsk
 - B. * Morshin
 - C. Kuyal'nik
 - D. Truskavets
 - E. Nemirov
448. What norm diastase is:
- A. * To 160
 - B. To 50
 - C. To 200
 - D. To 300
 - E. To 1200
449. What operation is most often used for localization the formed pseudocyst in the area of tail the pancreas:
- A. Cystojejunostomy on the eliminated loop
 - B. External draining the cyst
 - C. Cystogastrostomy
 - D. * Cystoduodenostomy
 - E. Cystoenteroanastomosis
450. What operation is used for suppuration the pseudocysts of pancreas:
- A. Cystojejunostomy on the eliminated loop
 - B. * External draining the cyst
 - C. Cystogastrostomy
 - D. Cystoduodenostomy
 - E. Cystoenteroanastomosis
451. What operation is used for the pseudocyst of pancreas in the 3th stage of its forming:
- A. * Cystojejunostomy on the eliminated loop
 - B. External draining the cyst
 - C. Cystogastrostomy
 - D. Cystoduodenostomy
 - E. Cystoenteroanastomosis

452. What operation on a pancreas is indicated at the oedematous form the acute pancreatitis:
- A. * Interference on a pancreas is not needed
 - B. Pancreatectomy
 - C. Omentopankreatopeksy
 - D. Abdominisation pancreas
 - E. Marsupialization
453. What preparation does behave to blocker H₂-retseptors?
- A. * tavegil
 - B. obzidan
 - C. hystdol
 - D. cerucal
 - E. oraza
454. What preparation does behave to blocker of muscarine receptors of coating cages?
- A. cymetidin
 - B. eglonin
 - C. * gastocepini
 - D. etimsiloli
 - E. vinylin
455. What preparation is applied at violation the extrasecretory function of pancreas at a chronic pancreatitis:
- A. Pyracetam
 - B. Papaverin
 - C. Pantocrin
 - D. * Panzinorm
 - E. Panthenol
456. What preparation is applied at violation the extrasecretory function pancreas at a chronic pancreatitis:
- A. Pyracetam
 - B. Papaverin
 - C. Pantocrin
 - D. * Mezim-forte
 - E. Panthenol
457. What preparation is attributed to the proteases inhibitors:
- A. Garamycin
 - B. Gaviskon
 - C. * Gordox
 - D. Halidor
 - E. Gramicidin
458. What preparation is attributed to the proteases inhibitors:
- A. Tocopherol
 - B. Triampur
 - C. Tagamet
 - D. * Trasylol
 - E. Trypsin
459. What preparation is not attributed to the inhibitors proteases:
- A. Pantripin

- B. Kontrikal
 - C. Gordox
 - D. Trasylol
 - E. * Trypsin
460. What preparations from the cytostatic group use for intensifying the chronic pancreatitis:
- A. Cyanocobalamin
 - B. Methyluracil
 - C. * 5-fluorouracil
 - D. Furadolizon
 - E. Mezimforte
461. What preparations, except for other properties, own yet and a bacteriostatic effect on *Helicobacter pylori*
- A. * all are transferred preparations
 - B. Almagel
 - C. Vinylin
 - D. De-nol
 - E. Claritromycin
462. What primary purpose treatment the patient with fatty pancreatonecrosisto the operation is:
- A. Liquidations the pain
 - B. * Disintoxication the organism
 - C. Liquidations crampy the big duodenal papilla
 - D. Declines secretory activity the pancreas
 - E. Improvements microcirculation
463. What primary purpose treatment the patients with the heavy form of hemorrhagic pancreatonecrosis to the operation is:
- A. Liquidations the pain
 - B. * Disintoxication the organism
 - C. Liquidations crampy the big duodenal papilla
 - D. Declines secretory activity the pancreas
 - E. Improvements microcirculation
464. What products are recommended in the diet of № 1?
- A. * hen in a steam kind
 - B. pancakes
 - C. raw egg-white
 - D. bread rye fresh
 - E. acute cheeses
465. What syndrome is characteristic for hemorrhagic erosive gastritis?
- A. * ulcerous
 - B. hemorrhagic;
 - C. pain;
 - D. all answers are correct;
 - E. all answers are not correct.
466. What time urgent operations are executed at acute bleeding
- A. * 6 – 12 hours;
 - B. 6 – 10 hours;
 - C. 6 – 8 hours
 - D. 6 – 14 hours;

- E. 6 – 20 hours
467. What violation of mineral exchange is characteristic for patients with ulcerous illness of stomach and intestine
- hypocalcemia
 - * hypokaliemia
 - Hyponatremia
 - Hypercalcemia
 - hyperkaliemia
468. When apply Teylor's method at ulcerous illness
- * at conservative treatment perforated ulcers
 - at conservative treatment sanguifluous ulcers
 - at conservative treatment penetration ulcers
 - at conservative treatment malignization ulcers
 - at conservative treatment of cicatrical pylorostenosis
469. With the purpose preparation to operation the patient with the protracted icterus of bail-stone diseases origin and phenomena hepatic insufficiency, it is necessary to make
- Endoscope papilotomy, throughskin transhepatic draining of hepaticocholedoch, endoscope papilotomy and nosebilliar draining
 - Throughskin transhepatic draining of the hepaticocholedoch, enteropersorption, lymphopersorption or hemopersorption, endoscope papilotomy and nosebilliar draining
 - * All right
 - Laparoscopic cholecystostomy, nosebilliar draining, throughskin transhepatic draining of hepaticocholedoh
 - Laparoscopic cholecystostomy, nosebilliar draining, throughskin transhepatic draining of hepaticocholedoch, endoscope papilotomy and nosebilliar draining
470. With transferring of stone from a gall-bladder in the common bile duct does not develop:
- Hepatic colic
 - Icterus
 - Festering cholangitis
 - Stenotic papillitis
 - * Syndrome by Badd-Khiary
471. A patient 2 hours ago fallen down from the first floor. State heavy. There are signs of the diffusive peritonitis. Survey sciagraphy of stomach is executed. What from roentgenologic symptoms diagnosis of break of cavernous organ will confirm?
- hight standings of diaphragm dome
 - Kloybers bowls
 - * free gas in an abdominal region
 - a free liquid in an abdominal region
 - infiltration in an abdominal region
472. A patient 2 hours ago got a blow in a stomach. Delivered in a urgent clinic in a grave condition with suspicion on the break of cavernous organ. What method of roentgenologic research will allow to specify a diagnosis?
- laparocentzis
 - laparoscopy
 - * sciagraphy of stomach
 - contrasting X-ray examination
 - irrigoscopy

473. A patient 40 years old, suffered ulcerous diseases of stomach. Last 2 days the pain became less intensive, but weakness and dizziness were appeared. Rose from a bed and lost consciousness. Pale. There are insignificant pains in epigastrium. It is
- Combination perforation with bleeding
 - Perforation
 - Malignization of ulcer
 - Stenosis of ulcer
 - * Gastroenteric bleeding
474. A patient entered to urgent with closed trauma of stomach. At an inspection are positive symptoms the irritation of peritoneum. The damage of internalss is suspected. What method of diagnostics does use for confirmation the diagnosis?
- angiography
 - X-ray examination
 - Sonography
 - * diagnostic laparotomy
 - diagnostic puncture
475. A patient entered urgent clinic in a grave condition. Pulse is 112 in min., AP - 11060, T - 35,1 C. It was found diagnosis the diffusive peritonitis. What treatment is rotined a patient?
- laparotsentez
 - laparoscopy
 - * operation
 - antibiotic
 - puncture
476. A patient entered urgent in a clinic on 3 days from the beginning of disease. The state is heavy, adynamic. Face of Hippocrates, pulse 138 in 1 min, AP - 8040. A stomach is blown away, moderato sickly at palpation. Shchotkin-Blyumbergs symptom is doubtful. A liquid is determined in the lower departments the stomach. A liquid, stinking excrement departs through gaping sphincter. That does explain the state of patient?
- intestinal impassability
 - * diffusivr peritonitis
 - mesenteric ischemia
 - toxic dilatation of colon
 - acute pancreatitis
477. A patient got the trauma of stomach 3 hours ago. Delivered in a urgent clinic with complaints about tormina. The lines of person are focus. Positive symptoms the irritation of peritoneum. At survey X-ray examination is found out free gas under the dome of diaphragm. A diagnosis is set: break of cavernous organ. What type of treatment is most expedient?
- cold on a stomach
 - laparotsentez
 - laparoscopy
 - * operative
 - antibiotic
478. A patient grumbles about great pain in a stomach, which arose up suddenly 6 hours ago. The diagnosis of peritonitis is set. What symptom is most characteristic for this diagnosis?
- increases of temperature
 - tachycardia
 - leucocytosis
 - tension of muscles the abdominal wall

- E. * irritations of peritoneum
479. A patient suffers a stenocardia. Became ill suddenly after the physical loading. Complaints about pain in a epigastric area, which spread on the right half of stomach. Positive Shchotkin-Blyumbergs symptom. Rectal – overhang and painfulness the front wall of rectum. It is not discovered the free gas on the survey sciagram of stomach. What is most reliable diagnosis?
- A. abdominal form of heart attack the myocardium
 - B. acute cholecystitis
 - C. acute pancreatitis
 - D. * peritonitis
 - E. peritonitis of apendicular character
480. A prophylaxis and treatment of postoperative enteroplegias at peritonitis is
- A. gastrotomy
 - B. gastrointestinotomy
 - C. * nasogastrointestinal intubation
 - D. intubation of abdominal region
 - E. intubation of stuffing-box bag
481. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. * malignization ulcers
 - C. ulcerous anamnesis more than 10 years
 - D. heavy pain syndrome, proof heartburn
 - E. relapse ulcer after vagotomy
482. Absolute sign of unstable hemostasis
- A. * profluvium blood from a vessel;
 - B. absence blood in a stomach and bulb of duodenum;
 - C. presence light blood and faltungs of blood in a stomach;
 - D. all answers are correct;
 - E. all answers are not correct
483. Acute pancreatitis with a heavy flow treat in terms:
- A. Ambulatory
 - B. Permanent establishment
 - C. * Department of intensive therapy
 - D. All answers are faithful
 - E. A faithful answer is not present
484. After time of origin complications acute pancreatitis select:
- A. Premature and remote
 - B. Urgent and deferred
 - C. Primary and second
 - D. * Early and late
 - E. Any of variants faithful
485. After what operation at ulcerous illness the natural arcade of meal is saved on a digestive tract
- A. Valter-Braun's gastroenterostomy
 - B. not saved after any operation
 - C. resection by Bilrot II
 - D. * resection by Bil'rot I
 - E. saved after all transferred operations

486. After what operation innervation of pyloric department of stomach is saved
- A. * selective vagotomy
 - B. barrel vagotomy
 - C. selective proximal vagotomy
 - D. at all transferred
 - E. not saved after all operations
487. Agents, which cause peritonitis, can be all except for:
- A. urines at the break of urinary bladder
 - B. tables of contents the stomach during the perforation of ulcer
 - C. to blood at the trauma of stomach
 - D. biles during the perforation of gall-bladder
 - E. * air in an abdominal region after laparoscopy research
488. All surgical interferences at the destructive forms of acute pancreatitis divide on:
- A. * Early, late, deferred operations
 - B. Primary, second, repeated operations
 - C. Invasion, not invasion operations
 - D. Complicated, operations are not complicated
 - E. Not divided
489. Among acute surgical diseases acute pancreatitis occupies:
- A. First place
 - B. * Third place
 - C. Fifth place
 - D. Second - third place
 - E. Most widespread
490. As the first period flowing of acute pancreatitis is named:
- A. * Haemodynamic violations and pancreatic shock
 - B. To functional insufficiency of parenchymatous organs
 - C. Degenerative and festerings complications
 - D. All answers are faithful
 - E. A right answer is not present
491. As the second period flowing of acute pancreatitis is named:
- A. * Haemodynamic violations and pancreatic shock
 - B. To functional insufficiency of parenchymatous organs
 - C. Degenerative and festerings complications
 - D. All answers are faithful
 - E. A right answer is not present
492. As the third period flowing of acute pancreatitis is named:
- A. Haemodynamic violations and pancreatic shock
 - B. * To functional insufficiency of parenchymatous organs
 - C. Degenerative and festerings complications
 - D. All answers are faithful
 - E. A right answer is not present
493. Aseptic inflammation of peritoneum can be caused:
- A. by a collibacillus
 - B. by staphylococuss
 - C. * by pancreatitis juice

- D. by an abscess
 - E. by intestinal maintenance
494. At a subdiaphragmatic abscess in a clinical picture characteristically all following, except for:
- A. declines the respiratory excursion of lights.
 - B. high standing of diaphragm dome.
 - C. concord pleurisy.
 - D. basale atelectasis of lights.
 - E. * blood spitting
495. At a subhepatic abscess can take place all, except for:
- A. pains in a thorax with an irradiation in a supraclavicular area
 - B. reactive pleurisy
 - C. * Courvoisier's symptom
 - D. Senator's symptom
 - E. Dyushen's symptom
496. At beginning bleeding from an ulcer
- A. * pain diminishes
 - B. pain increases
 - C. there is knife-like pain
 - D. character of pain does not change
 - E. girdle pain
497. At bleeding emergency operative interferences are executed
- A. * to 3 hours
 - B. to 1,5 hour
 - C. to 6 hours
 - D. to 8 hours
 - E. 6 – 12 hours
498. At festering peritonitis the disorder of hemodynamics not conditioned:
- A. by the decline of volume the circulatory blood
 - B. * by the increase of volume the circulatory blood
 - C. by the decline of tone the vascular wall
 - D. by the change of properties the hemorheologys
 - E. by violation of cardiovascular activity
499. At III stage blood loss at the bleeding ulcer the patient loses
- A. more than 25 % blood volume
 - B. * more than 30 % blood volume
 - C. more than 20 % blood volume
 - D. more than 15 % blood volume
 - E. more than 35 % blood volume
500. At pancreatitis abscesses and infected necroses execute such operations, except for:
- A. Opening of abscess with draining
 - B. Pancreaticnecrosekvestrektomy
 - C. Pancreaticsekvestrektomy
 - D. Pancreaticsekvestrektomy with laparostomy
 - E. * Total pancreatotomy
501. At peritonitis intestinal impassability develops, as a rule:

- A. mechanical
 - B. dynamic
 - C. spastic
 - D. * paralytic
 - E. mixed
502. At peritonitis of violation the proteometabolism characterized:
- A. by the increase of concentration the albumen
 - B. by the increase of concentration the globulins
 - C. diminishing of concentration the albumen
 - D. * diminishing of the albumen - globulins coefficient
 - E. by the increase of the albumen - globulins coefficient
503. At suspicion on a subdiaphragmatic abscess the followings methods of diagnostics are rotined, except for:
- A. * laparoscopy.
 - B. Sonography.
 - C. X-ray examination of thorax.
 - D. X-ray examination of abdominal region.
 - E. computer tomography
504. At suspicion on the abscess of Duglas space all followings methods of diagnostics are rotined, except for:
- A. rectal inspection.
 - B. * proctoscopy.
 - C. Sonography.
 - D. computer tomography.
 - E. vaginal research
505. At the duodenum ulceroperation of choice is
- A. * resection by Bilrot I
 - B. resection by Bilrot II
 - C. resection of duodenum
 - D. selective proximal vagotomy
 - E. sewing up of ulcer
506. At the gastroenteric bleeding the middle degree of blood loss is diagnosed at next indexes
- A. Hb below 80 g/l
 - B. * Hb 80-100 g/l
 - C. red corpuscles below $2,5 \cdot 10^{12}/l$
 - D. red corpuscles of $3,5-4,0 \cdot 10^{12}/l$
 - E. Ht below 25%
507. At the III item of activity hemostasis and III sage blood loss from the I – III sage blood loss indicated
- A. * urgent operations (6 – 12 hours);
 - B. emergency operations (to 3 hours);
 - C. exigent operations (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
508. At the V item activity of hemostasis and at the recurrent bleeding of the I – III item of blood loss indicated
- A. * emergency operations (to 3 hours);

- B. urgent operations (6 – 12 hours);
 - C. exigent (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
509. At ulcerous illness can a bleeding source be
- A. artery;
 - B. veins;
 - C. shallow vessels and ulcers;
 - D. all answers are not correct.
 - E. * all answers are correct
510. At what disease pain of girdle character is characteristic:
- A. Gastric ulcers
 - B. Acute cholecystitis
 - C. Intestinal impassability
 - D. * Acute pancreatitis
 - E. Acute cystitis
511. At what pathology is absence pulsation of abdominal aorta
- A. * Acute cholecystitis
 - B. Acute pancreatitis
 - C. Perforated ulcer
 - D. Intestinal obstruction
 - E. Acute appendicitis
512. At what pathology is appearance cyanosis the sides of stomach:
- A. * Acute pancreatitis
 - B. Perforated ulcer
 - C. Acute cholecystitis
 - D. Intestinal obstruction
 - E. Acute appendicitis
513. At what pathology is appearance of sickliness in left costal-vertebral coal:
- A. * Acute pancreatitis
 - B. Acute cholecystitis
 - C. Perforated ulcer
 - D. Intestinal obstruction
 - E. A right answer is not present
514. Atypical clinical motion of postoperative peritonitis is conditioned setting in a postoperative period:
- A. spasmolytic
 - B. anticoagulant
 - C. * anaesthetic
 - D. analeptics
 - E. cardiac
515. Bergman's sign is characteristic for
- A. * bleeding ulcer
 - B. for cicatricial-ulcerous pylorostenosis
 - C. perforated ulcers
 - D. penetration ulcers
 - E. malignization ulcers

516. Berhstein's sign characteristic for
- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorostenosis
517. Bleeding ulcer, complicated blood loss III stage degrees, requires
- A. * blood and its components transfusions
 - B. transfusion of salt solutions
 - C. transfusion of colloid solutions
 - D. transfusion of salt and colloid solutions
 - E. infusion therapy does not need
518. Blood loss I stage characterized such indexes
- A. Ht 48-44, Hb 120
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 31-23, Hb 80
 - D. * Ht 38-32, Hb 100
 - E. Ht 44-40, Hb 110 /?
519. Blood loss II stage characterized
- A. * Ht 23 and below, Hb 50 and below
 - B. Ht 31-23, Hb 80
 - C. Ht 44-40, Hb 110
 - D. Ht 48-44, Hb 120
 - E. Ht 48-44, Hb 120
520. Blood loss III stage characterized a degree such indexes
- A. * Ht 31-23, Hb 80
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 38-32, Hb 100
 - D. Ht 44-40, Hb 110
 - E. Ht 48-44, Hb 120
521. Bonde's sign at acute pancreatitis:
- A. * Swelling the stomach only in epigastrium
 - B. Cyanosis sides of stomach and trunk
 - C. Cyanosis skin of stomach
 - D. Ictericness round a belly-button
 - E. Cyanosis of hands
522. Characteristic complication acute pancreatitis is:
- A. * Pancreonecrosis
 - B. Pylephlebitis
 - C. Hepatocirrhosis
 - D. Veritable pancreas cyst
 - E. Hepatitis
523. Characteristic complication the acute pancreatitis is:
- A. Paranephritis
 - B. Douglas's abscess
 - C. Pylephlebitis

- D. Cyst of pancreas
 - E. * Pancreonecrosis
524. Conservative treatment the acute pancreatitis includes:
- A. * Hunger
 - B. Povzner's diet №5
 - C. Povzner's diet №15
 - D. Moderation in a meal
 - E. Morning gymnastics
525. De-Cerven's sign is characteristic for
- A. bleeding ulcer
 - B. * perforated ulcers
 - C. penetrated ulcers
 - D. malignitized ulcers
 - E. for cicatricial-ulcerous pylorostenosis
526. Decision role in differential diagnostics of peritonitis and acute vascular purpura is a symptom:
- A. * hemorrhagic rash on a skin
 - B. acute pain in a stomach
 - C. systole noise above the abdominal department of aorta
 - D. absence of pulsation of abdominal department of aorta
 - E. melena at rectal research
527. Decision role in differential diagnostics of peritonitis and break the bone of pelvis is:
- A. to appoint antibiotics
 - B. to appoint anaesthetic
 - C. to execute laparocentthesis
 - D. * to execute laparoscopy
 - E. to execute survey sciagraphy of abdominal region
528. Decision role in differential diagnostics the peritonitis and dissecting aneurysm of aorta , there is a symptom:
- A. aperistalsis
 - B. acute pain in a stomach
 - C. * systole noise above the abdominal department of aorta
 - D. absence of pulsation of abdominal department of aorta
 - E. melena at rectal research
529. Diet at bleeding gastric and duodenum ulcers
- A. * Meulengracht's
 - B. 1 by Pevznerom
 - C. 5 by Pevznerom
 - D. 15 by Pevznerom
 - E. 7 by Pevznerom
530. Diffusive festering peritonitis can be investigation of all transferred diseases, except for:
- A. perforations Meckel's diverticulum
 - B. destructive appendicitis
 - C. * stenosis of large duodenal nipple
 - D. Richter strangulation of hernia
 - E. acute intestinal impassability

531. Disappearance or diminishing the pain with beginning of bleeding from an ulcer is
- * Bergman's sign
 - Spazarskiy's sign
 - Mendel's sign
 - De Keven's sign
 - Eleker's sign
532. Draining the abdominal region is conducted at:
- phlegmonous appendicitis without exudation
 - * gangrenous appendicitis with exudation
 - phlegmonous appendicitis with serosal exudation odourless
 - there is not a right answer
 - catarrhal appendicitis
533. Duration the period of primary shock at a perforated ulcer
- * 3-6 hours
 - 6-12 hours
 - 1-3 hours
 - 12-24 hours
 - 24-36 hours
534. Early complications the acute pancreatitis is not:
- * Fistula of pancreas
 - Pancreatic shock
 - Collapse
 - Ferment peritonitis
 - Pancreatic delirious syndrome
535. Eleker's sign is characteristic for
- * perforated ulcers
 - bleeding ulcer
 - penetrated ulcers
 - malignized ulcers
 - for cicatricial-ulcerous pylorostenosis
536. ERCP apply at:
- Postcholecystectomy syndrome
 - Stenosing papillitis
 - * Stenosis the supraduodenal department of choledoch
 - Stricture the terminal department of choledoch
 - Mechanical icterus
537. Esophagogastroduodenoscopy can find out next changes in a stomach, except for
- tumours
 - ulcers
 - bleeding polypuses
 - erosions
 - * changes of evacuation function
538. Fibrinogenous impositions on a peritoneum are not at peritonitis:
- * serosal
 - fibrinogenous
 - festering
 - putrid

- E. excrement
539. For a patient, suffering ulcerous illness, sudden great pain in an epigastrium and unclear symptoms of peritonitis appeared. During subsequent days the display of these symptoms diminished, the state of patient had become better. It is possible to suppose at such clinic
- typical perforation the ulcer
 - * covered perforation
 - preperforative state
 - intensifying of ulcerous illness
 - there is not a right answer
540. For a perforation declivous organ all is characteristic in a free abdominal region, except for:
- acute began pains.
 - wooden belly.
 - collapse.
 - * oliguria.
 - tachycardia.
541. For bleeding ulcer characteristic sign is
- * pain in an epigastrium;
 - knife-like pain;
 - signs irritation of peritoneum;
 - presence fresh blood in incandescence
 - melena;
542. For bleeding ulcer characteristically
- * melena
 - tension the muscles of front abdominal wall
 - Spazarskiy's sing
 - sickliness the back vault of vagina
 - irradiation pain in a shoulder or shoulder-blade
543. For diagnostics of acute pancreatitis most informing is:
- * Sonography
 - CT
 - Cholangiography
 - Esophagogastroduodenoscopy
 - Colonoscopy
544. For motion of disease ulcerous illness of middle weight characteristically
- development of complications
 - * relapses 1-2 times per a year
 - 4 and anymore relapses on a year
 - 5 and more relapses are on a year
 - 3 and anymore relapses on a year
545. For pancreonecrosis characteristically is:
- * Rapid progress, strengthening pain, proof enteroplegia, growth haemodynamic violations
 - Rapid progress, diminishing pain, strengthening of моторики of intestine, growth haemodynamic violations
 - Slow progress, strengthening pain, phase of imaginary prosperity.
 - Abortive flow, toxemia, development shock.
 - Appearance light interval

546. For perforative appendicitis characteristically
- tension the muscles of front abdominal wall
 - there is the sudden strengthening of stomach-aches
 - rapid growth of clinical picture the peritonitis
 - Razdolskuy's symptom
 - * all transferred
547. For perforated ulcer characteristically
- * tension the muscles of front abdominal wall
 - melena
 - vomiting by coffee-grounds
 - high intestinal impassability
 - vomiting stagnant gastric maintenance
548. For peritonitis in the first 24 hours not typical
- aperistalsis intestine
 - * Kullenkamp's symptom
 - Tachycardia
 - dry language
 - tension the muscles of abdominal wall and positive Shchetkin-Blyumberg's symptom
549. For peritonitis there is a not characteristic symptom:
- Shchetkin-Blyumberg's symptom
 - Voskresenskiy's symptom
 - Kulenkampf's symptom
 - * Moebius's symptom
 - Krymov's symptom
550. For pneumoperitoneum is characteristic symptom
- * Zhober's;
 - Khelatid's;
 - Podlag's;
 - Vigats's;
 - Udin's.
551. For the abortive flowing characteristically:
- * A process limited to the acute edema with convalescence in 7-8 days
 - A process limited to tearing away of the pathologically changed gland
 - A process limited to tearing away of the pathologically unchanged gland
 - A disease completed so not attaining clinical displays
 - Changes from the side of organ are not present
552. For the heavy flow of ulcerous illness characteristically
- 2 and anymore relapses on a year
 - * 3 and anymore relapses on a year
 - 4 and anymore relapses on a year
 - 5 and more relapses are on a year
 - 6 and more relapses are on a year
553. For the heavy flow of ulcerous illness characteristically
- * development of complications
 - seasonal exacerbation more not frequent 1-2 times per a year
 - 1-2 relapse on a year

- D. liquid, but protracted exacerbation
 - E. exacerbation duration more than 10 days
554. For the late stage of peritonitis all is characteristic, except for:
- A. swelling of stomach
 - B. hypovolemia
 - C. disappearance of intestinal noises
 - D. hypoproteinemia
 - E. * increased peristalsis
555. For the reactive stage of festering peritonitis not characteristically:
- A. acute sickliness the stomach at palpation
 - B. positive Shchetkin-Blyumberg's symptom
 - C. tension of muscles the front abdominal wall
 - D. * face of «Hippocrates»
 - E. tachycardia
556. For the terminal stage of peritonitis not characteristically:
- A. tachycardia
 - B. * bradycardia
 - C. hyperthermia
 - D. falling of arteriotony
 - E. dynamic intestinal impassability
557. For what pathology appearance of violet spots on the skin of person and trunk is characteristic:
- A. Perforated ulcer
 - B. Acute cholecystitis
 - C. * Acute pancreatitis
 - D. Intestinal obstruction
 - E. Acute appendicitis
558. For what purpose in treatment of diffusive festering peritonitis does execute nasointestinal intubation?
- A. account of losses the liquid through a gastroenteric highway.
 - B. control of electrolyte composition the intestinal maintenance
 - C. * prophylaxis of intestinal impassability
 - D. stimulation of the intestinal peristalsis
 - E. suppression of the intestinal peristalsis
559. From what department degestive tract developmentp more frequent than all the bleeding at the Mallory-Weiss syndrome
- A. gastric fundus
 - B. * cardial pert;
 - C. pyloric department;
 - D. from duodenal;
 - E. from a thick intestine
560. Giant ulcer is an ulcer measuring
- A. over 4,5 cm
 - B. * over 3 cm
 - C. over 4 cm
 - D. over 5 cm
 - E. over 3,5 cm

561. Hemobilia is
- A. * all answers are correct;
 - B. bleeding the bilious ways and liver;
 - C. bleeding the general bilious channel;
 - D. bloody clot in the big duodenal papilla;
 - E. all answers are not correct.
562. Holsted's sign at acute pancreatitis:
- A. Violet spots on face and trunk
 - B. Cyanosis sides of stomach and trunk
 - C. * Cyanosis skin of stomach
 - D. Ictericity round a belly-button
 - E. Cyanosis of hands
563. How is the diagnosis of the general peritonitis set to the operation?
- A. roentgenologic
 - B. anamnestic
 - C. by laboratory determination the signs of inflammatory reaction
 - D. * on clinical signs
 - E. on the level secretion the gastric juice
564. How many is the period of haemodynamic violations and pancreatic shock lasts:
- A. * 1-3 days
 - B. 3-7 days
 - C. More 7 days
 - D. 2 weeks
 - E. 2 hour
565. How many is the period of degenerative and festering complications lasts:
- A. 1-3 days
 - B. 3-7 days
 - C. * More 7 days
 - D. 2 weeks
 - E. 2 hour
566. How many is the period of functional insufficiency of parenchymatous organs lasts:
- A. 1-3 days
 - B. * 3-7 days
 - C. More 7 days
 - D. 2 weeks
 - E. 2 hour
567. In a patient with pains in an epigastric area, what was displaced from a right iliac area. There was nausea and single vomiting. A patient accepted an analgin and put a hot-water bottle to the stomach, pains calmed down whereupon. On 2 days pains recommenced, spread on all stomach, the frequent vomiting appeared. The state of patient is heavy. Consciousness entangled. Euphoria. Pulse 128 in min, AP - 95/60. Language is dry. A stomach is tense in all departments. Temperature 37,2. Leucocytes in blood of 18? 109/l. Diagnosis
- A. * acute appendicitis, terminal stage of peritonitis
 - B. typhoid, perforation of typhoidal ulcer
 - C. perforation gastric ulcer
 - D. gastric bleeding
 - E. there is not a right answer

568. In classic motion of peritonitis select the stages:
- early, intermediate, late
 - reactive, intermediate, late
 - toxic, intoxication, terminal
 - * reactive, toxic, terminal
 - reactive, toxic, late
569. In the dynamics of acute peritonitis it is necessary positive to consider
- * decline of amount the leucocytes
 - increase of amount the leucocytes
 - leucocytosis with the change of leukocytic formula to the left
 - growth of the leukocytic index intoxication
 - leukopenia
570. In treatment of the diffusive peritonitis of appendicitis origin a basic value has
- * all transferred
 - antibacterial therapy
 - correction water-electrolyte violations
 - removal of source of peritonitis
 - sanitization of the abdominal region
571. In treatment of the diffusive peritonitis of appendicitis origin a basic value has
- correction water-electrolyte violations
 - sanitization of abdominal region
 - removal the source of peritonitis
 - * all answers are faithful
 - antibacterial therapy
572. In what area of stomach practically never is not origin of ulcers, or it is extraordinarily rarely?
- small curvature of stomach;
 - back wall of stomach, nearer to small curvature;
 - large curvature of stomach
 - * cardiac part of stomach;
 - pylorus.
573. In what vein is a venous outflow carried out in from a stomach?
- * V. Portae;
 - V. odd;
 - V. pair;
 - V. overhead hollow;
 - V. lower hollow;
574. Indication to early operative interference at acute pancreatitis is:
- Acute pancreatolysis
 - Acute oedematous pancreatitis
 - * Progressive multiple organ failure what not added conservative therapy during 48-72 hours
 - Acute fatty pancreatitis
 - Forming of pseudocyst
575. Kerte's sing at acute pancreatitis:
- Absence pulsation the abdominal aorta

- B. Sickliness in left costal-vertebral coal
 - C. * Sickliness and proof tension the muscles in an epigastrium with passing to left subcostal area
 - D. Icteritiousness round a belly-button
 - E. Skin hyperesthesia in projection the gland
576. Kulen's sign at acute pancreatitis:
- A. Violet spots on face and trunk
 - B. Cyanosis sides of stomach and trunk
 - C. Cyanosis skin of stomach
 - D. * Icteritiousness round a belly-button
 - E. Cyanosis of hands
577. Laparostomy at the diffusive peritonitis used with a purpose
- A. * to repeated sanitization the abdominal region
 - B. extracorporal dialysis
 - C. hemosorption
 - D. laparoscopy
 - E. stimulations the peristalsis
578. Large ulcer is an ulcer measuring
- A. 1-4 cm
 - B. 1-3 cm
 - C. 3-5 cm
 - D. 2- 6 cm
 - E. * 2-3 cm
579. Least answers a subhepatic abscess:
- A. Senator's symptom
 - B. Dyushen's symptom
 - C. Liten's symptom
 - D. * Rovzing's symptom
 - E. Shchotkin-Blyumberg's symptom
580. Little ulcer it is an ulcer measuring
- A. * to 0,5 cm
 - B. 0,5-1 cm
 - C. to 1,0 cm
 - D. 3 to 1,5 cm
 - E. 0,5-1,5 cm
581. Meets the most frequent localization bleeding the digestive tract is
- A. gullet;
 - B. stomach;
 - C. rectum;
 - D. * duodenum;
 - E. colon
582. Melena is
- A. black designed chair
 - B. * black liquid tarry chair
 - C. a discoloured liquid excrement
 - D. foamy stinking emptying of black
 - E. an excrement designed veined blood

583. Melena is a characteristic sign
- * bleeding ulcer
 - for cicatrical-ulcerous pylorus stenosis
 - perforeted ulcers
 - penetration ulcers
 - malignization ulcers
584. Mayo-Robson's sign at acute pancreatitis:
- Absence pulsation the abdominal aorta
 - * Sickliness in left costal-vertebral coal
 - Sickliness and proof tension the muscles in an epigastrium with passing to left subcostal area
 - Icteritiousness round a belly-button
 - Skin hyperesthesia in projection the gland
585. Middle laparotomy must be conducted at:
- * diffusive peritonitis
 - local unlimited peritonitis
 - abscess of Duglas space
 - periappendiceal infiltration
 - acute appendicitis
586. Mondor's sign at acute pancreatitis:
- * Violet spots on face and trunk
 - Cyanosis sides of stomach and trunk
 - Cyanosis skin of stomach
 - Icteritiousness round a belly-button
 - Cyanosys of hands
587. Most frequent reason of peritonitis
- posoperative complication
 - acute trauma of stomach
 - acute cholecystitis
 - * acute appendicitis
 - acute intestinal impassability
588. Most informing method at a bleeding ulcer
- survey sciagraphy the organs of abdominal region
 - * EFGDS
 - sciagraphy the stomach with contrasting
 - Sonography
 - Laparoskopy
589. Name class complications of ulcerous illness
- bleeding, pyloristhenosis, second pancreatitis, malignization, perforation
 - * perforation, penetration, bleeding, pyloristhenosis, malignization
 - malignization, pyloristhenosis, penetration, anaemia, perforation
 - bleeding, perforation, second pancreatitis, anaemia, malignization
 - perforation, peritonitis, pancreatitis, bleeding, penetration
590. Name most frequent complication after ERDPH:
- * Pancreatitis
 - Cholangitis

- C. Pancreatic sepsis
 - D. Reactive cholecystitis
 - E. Obstructing papillitis
591. Name principal reason the acute pancreatitis:
- A. Trauma the pancreas
 - B. * Bile-stone diseases
 - C. Alimentary factor
 - D. Chronic alcoholic pancreatitis
 - E. Cardiospasm
592. Name the optimum volume of operation at acute biliary pancreatitis:
- A. Deleting exsudate from an abdominal region
 - B. Decapsulation pancreas
 - C. Pancreatectomy
 - D. * Sanitization and draining the bilious ways
 - E. Draining the chanel of pancreas
593. Operating access at operations on a stomach
- A. * Upper-middle laparotomy
 - B. Lower-middle laparotomy
 - C. Pararectum access
 - D. Volokovich-Dyakonov's access
 - E. Pfanenhtil's access
594. pathognomonic symptom at acute pancreatitis is:
- A. Pasternatskiy's sing
 - B. * Kulen's sing
 - C. Ker's sing
 - D. Lenander's sing
 - E. Roving's sing
595. Patient which the gastroenteric bleeding in house is necessary
- A. * To send a patient in surgical permanent establishment
 - B. To appoint rest, enter Cacl, vicasol
 - C. To wash a stomach, appoint a cold, rest of supervision
 - D. To send a patient in a therapeutic gastroenterology separation
 - E. A right answer absents
596. Peritonitis does not develop at the next form of acute appendicitis
- A. * catarrhal
 - B. phlegmonous
 - C. gangrenous
 - D. perforative
 - E. gangrenous-perforative
597. Postoperative peritonitis is characterized a flow:
- A. typical
 - B. * atypical
 - C. stormy
 - D. with the expressed pain reaction
 - E. with the expressed intoxication
598. Preoperated complication of acute appendicitis

- A. * diffusive peritonitis
 - B. intra-abdominal bleeding
 - C. suppuration of wound
 - D. evisceration wounds
 - E. there are not a right answer
599. Preoperative preparation for patients from peritonitis does not provide:
- A. corrections the violations cardiovascular system
 - B. * laparocentzis
 - C. declines the intoxication
 - D. corrections the exchange violations
 - E. struggle with hy hypovolemia
600. Radical operation at a bleeding gastric ulcer and duodenum consists in
- A. sewing vessels on a draught;
 - B. * vagotomy or resection the stomach;
 - C. sewing vessels in an ulcer;
 - D. gastroenteroanastomosis;
 - E. all answers are faithful
601. Relaparotomy at diffusive festering peritonitis pursues:
- A. * repeated revision of abdominal region
 - B. repeated laparoscopy of abdominal region
 - C. repeated endoscopy of abdominal region
 - D. normalization the function of gall-bladder
 - E. normalization the function of urinary bladder
602. Relative absolute indication to operative treatment ulcerous illness is
- A. * penetration of ulcer
 - B. ulcerous anamnesis more than 15 years
 - C. malignization ulcers
 - D. perforation of ulcer
 - E. relapses more than 3 times per a year
603. Resection of stomach by Bilrot II belongs to
- A. * radical operation
 - B. palliative operation
 - C. draining operations
 - D. organ protect operation
 - E. does not belong to any group
604. Selective proximal vagotomy belongs to
- A. palliative
 - B. draining
 - C. * organ protect operation
 - D. resection
 - E. does not belong to any group
605. Signs of stable hemostasis
- A. * absence blood in a stomach and duodenum bulb;
 - B. presence the light blood and faltungs of blood in a stomach;
 - C. profluvium blood from a vessel;
 - D. all answers correct;
 - E. all answers are not correct

606. Signs of unstable hemostasis
- A. * the pulsation of vessel is determined;
 - B. the bottom ulcer is covered a fibrin;
 - C. profluvium blood from a vessel;
 - D. all answers are correct;
 - E. all answers are not correct.
607. Specific symptom of perforation declivous organ in a free abdominal region is:
- A. high leucocytosis.
 - B. absence of intestinal noises.
 - C. * pneumoperitoneum.
 - D. positive symptoms of irritation the peritoneum.
 - E. dulling of the percussion sound in the gently sloping places of abdominal region
608. Specify a criterion which grounds the choice of middle laoarotomy access at the deffusion festering peritonitis:
- A. minimum trauma the abdominal wall
 - B. minimum cut
 - C. * valuable revision the abdominal region.
 - D. minimum blood loss.
 - E. minimum level of infecting the wound
609. Specify obligatory measures which are conducted during an operation concerning widespread fibrinopurulent peritonitis:
- A. removal the source of peritonitis.
 - B. sanitization of the abdominal region.
 - C. decompression of intestine.
 - D. draining of abdominal region.
 - E. * all answers are faithful
610. Specify possible reasons of the pseudoperitoneal syndrome:
- A. uremia.
 - B. porphyria.
 - C. diabetic crisis.
 - D. nephrocolic.
 - E. * all transferred
611. Specify reason of use the derivatives of metronidasoli as an obligatory component of antibacterial therapy of widespread peritonitis?
- A. * removal of anaerobic microflora.
 - B. removal of mycotic flora.
 - C. removal of microflora of aerobic.
 - D. prophylaxis of intestinal worm invasion.
 - E. prophylaxis of widespread candidosis
612. Specify the most rational way the introduction of antibacterial preparations in treatment of diffusive festering peritonitis:
- A. peroral
 - B. hypodermic
 - C. intramuscular
 - D. * intravenous
 - E. intraperitoneal

613. Specify the optimum volume operation at acute biliar pancreatitis:
- Deleting exsudate from abdominal region
 - Decapsulation pancreas
 - Pancreatectomy
 - * Sanitization and draining bilious ways
 - Draining pancreas channel
614. Symptom of the toxic «scissors» at peritonitis it:
- increase of temperature and pulse
 - diminishing of temperature and pulse
 - * diminishing of temperature and increase of pulse
 - increase of temperature and diminishing of pulse
 - increase of temperature and diminishing of breathing frequency
615. Symptom of toxic «scissors» at the peritinitis it is correlation:
- * pulse and temperature
 - arteriotony and pulse
 - arteriotony and temperature
 - rectal and axillar temperature
 - rate breathings and temperatures
616. Tactic of surgeon at periappendiceal mas:
- operative treatment
 - * conservative treatment, systematic looking after a patient
 - there is not a right answer
 - supervision
 - punction
617. Tension of abdominal wall and stage peritonitis at acute appendicitis
- * absents, a stomach is swollen - terminal
 - absents, a stomach is not swollen - terminal
 - expressed, a stomach is not swollen - terminal
 - absents, a stomach is swollen - toxic
 - absents, a stomach is swollen – initial
618. Tension of muscles the right iliac area at the perforation of duodenal ulcer is explained
- by development of the diffusive peritonitis
 - by reflex connections through medullispinal nerves
 - * flowing down of gastric content in a right lateral channel
 - entering of air abdominal region
 - viscero0visceral connections with a vermicular appendix
619. The best method of treatment the subhepatic abscess is:
- thoracolaparotomy
 - lumbotomy
 - double-stage transpleural approach
 - laparotomy by Fedorov
 - * extrapleural extra-peritoneal method
620. The best variant the treatment of subhepatic abscess is:
- conservative treatment
 - extra-peritoneal section and draining
 - laparotomy, section and tamponing of cavity
 - * punction of abscess by a thick needle under control Sonography

- E. all transferred right
621. The complex treatment of festering peritonitis does not provide for:
- delete of primary hearth
 - * vagotomy
 - correction the metabolic violations
 - adequate therapy by antibiotics
 - struggle of paresis the intestine
622. The diagnostics criteria of the anaerobic peritonitis is
- stormy progress of disease
 - heavy festering intoxication
 - expressed enteroplegia
 - abundant amount of exsudate green-brown colors
 - * all is transferred
623. The exsudate painted blood in an abdominal region is observed always, except for:
- * tubercular peritonitis
 - violations of extra-uterine pregnancy
 - mesenteric ischemia
 - acute pancreatitis
 - twisted oothecoma
624. The favourable result of treatment the patients with peritonitis provide:
- early surgical interference
 - adequate operation
 - intravenous antibacterial therapy
 - methods of extracorporal dialysis
 - * all is transferred
625. The laboratory signs of total pancreonecrosis is:
- Growth glucose concentration
 - Diminishing maintenance fibrinogenum
 - * Growth activity diastase
 - Diminishing activity diastase
 - Growth index AST
626. The leading clinical symptoms the acute pancreatitis is:
- * Stomach-ache
 - Vomiting by „coffee-grounds”
 - Disuria
 - Febrile temperature of body
 - Lock
627. The leading symptom of peritonitis is:
- stomach-ache
 - enteroplegia
 - swelling of stomach
 - * symptoms the irritation of peritoneum
 - symptoms of the intestinal impassability
628. The methods of disintoxication at peritonitis are not:
- lymphosorbtion
 - hemisorption

- C. enterosorbition
 - D. plasmapheresis
 - E. * antibiotic
629. The most informing method the instrumental diagnostics of peritonitis is:
- A. * survey sciagraphy of abdominal region
 - B. lasparoscopy
 - C. angiography
 - D. gastroscopy
 - E. colonoscopy
630. The nosotropic mechanisms bleedingness at ulcerous illness is
- A. * all answers are correct.
 - B. permanent hyperemia all system of stomach
 - C. different degree dystrophy of superficial layers the mucus shell
 - D. accumulation the central mucopolysaccharides
 - E. hypoplastic, dystrophic processes
631. The secretory function stomach is carried out the next membrane of stomach
- A. * mucous membrane
 - B. internal muscular layer
 - C. serosal
 - D. mucous submembrane
 - E. external layer
632. The sign of the diffusive peritonitis is not
- A. * visible peristalsis
 - B. absence the peristaltic intestinal noises
 - C. sickliness of stomach at palpation in all departments
 - D. even tension the muscles of front abdominal wall
 - E. positive Shchetkin-Blyumberg's symptom
633. There is vomiting at peritonitis, as a rule:
- A. single
 - B. episodic
 - C. * frequent
 - D. abundant
 - E. scanty
634. To absolute indication to operative interference at ulcerous illness does not belong
- A. * scarry-ulcerous stenosis
 - B. perforation of ulcer
 - C. profuse bleeding
 - D. diameter ulcer a more than 3 cm
 - E. bleeding what does not stopped with conservative
635. To early complications acute pancreatitis attribute:
- A. Shock
 - B. Acute hepatic-kidney insufficiency
 - C. Poured out peritonitis
 - D. Icterus
 - E. * All answers are faithful
636. To the gastric – intestinal bleeding of un ulcerous etiology belong

- A. * Mallory-Weiss syndrome;
 - B. hemorrhagic erosive gastritis;
 - C. diseases by Randyu – Oslera – Vebera;
 - D. Menetrie's sing;
 - E. all answers are correct.
637. To the initial phase the peritonitis of appendicle origin does not behave
- A. sickliness the pelvic peritoneum at rectal research
 - B. tachycardia
 - C. * noticeable electrolyte changes
 - D. tendency to growth leucocytosis
 - E. tension of muscles the abdominal wall
638. To the late stage of peritonitis of appendicle origin does not behave
- A. dehydration
 - B. swelling of stomach
 - C. * increased peristalsis
 - D. hypoproteinemia
 - E. disappearance of intestinal noises
639. To the local isolated peritonitis does not attribute:
- A. subdiaphragmatic abscess
 - B. subhepatic abscess
 - C. interintestinal abscess
 - D. * primary idiopathic peritonitis
 - E. abscess cystic-rectal spaces
640. Turner's sing at acute pancreatitis:
- A. Violet spots on face and trunk
 - B. * Cyanosis sides of stomach and trunk
 - C. Cyanosis skin of stomach
 - D. Icteritiousness round a belly-button
 - E. Cyanosys of hands
641. Udin's sing at a perforated ulcer is
- A. * feeling at palpation shove the gases which penetrate through the perforated opening
 - B. dulling perforated sound in the lateral departments of stomach
 - C. disappearance of hepatic dullness
 - D. irradiation pain in a shoulder or shoulder-blade
 - E. sickliness the back vault of vagina
642. Vomiting coffee-grounds is a characteristic sign
- A. * bleeding ulcer
 - B. penetrative ulcers
 - C. perforated ulcers
 - D. malignizated ulcers
 - E. for cicatrical-ulcerous pylorus stenosis
643. Vomiting what arose up in 4-6 hours after eating characteristic for
- A. chronic alcoholic gastritis
 - B. cancer and ulcers of cardia
 - C. * pylorus ulcers
 - D. achalasia of gullet
 - E. ulcer and cancer the body of stomach

644. Voskresenskiy's sign at acute pancreatitis:
- * Absence pulsation the abdominal aorta
 - Sickliness in left costal-vertebral coal
 - Sickliness and proof tension the muscles in an epigastrium with passing to left subcostal area
 - Ictericity round a belly-button
 - Skin hyperesthesia in projection the gland
645. What nosotropic conditionality Voskresenskiy's sign at acute pancreatitis:
- * Inflammatory edema of pancreas
 - Reflex paresis of colon
 - Thrombosis of abdominal aorta
 - Embolism of abdominal aorta
 - Development of peritonitis
646. What a clinical flow can be at acute pancreatitis:
- Easy, middle, heavy
 - Acute, chronic
 - * Abortive, making progress
 - Edema, necrosis
 - Any variant
647. What basic method the treatment of acute pancreatitis is:
- Surgical
 - * Conservative
 - Homoeopathic
 - Physical therapy
 - A right answer is not present
648. What cages of pancreas are make glucagon:
- клетки
 - клетки
 - клетки
 - None of cages
 - D-клетки
649. What cages of pancreas are make insulin:
- клетки
 - клетки
 - клетки
 - None of cages
 - D-клетки
650. What colouring of chair is most characteristic for bleeding from the ulcer of stomach and duodenum?
- * Tarry excrement
 - Presence on the formed excrement of strokes of red blood
 - Littlechanged blood in an excrement
 - Excrement of the raspberry colouring with the admixtures of mucus
 - Acholic excrement
651. What complication the ulcerous illness of stomach is most characteristically for the patients of elderly and senile age

- A. perforation
 - B. perforation + bleeding
 - C. pylorus stenosis
 - D. malignization + penetration
 - E. * bleeding
652. What complications at a acute pancreatitis is behave to early:
- A. * Peritonitis
 - B. Phlegmon retroperitoneum space
 - C. Formation of pseudocysts
 - D. Development of saccharine diabetes
 - E. Intestinal impassability
653. What complications at a acute pancreatitis is behave to late:
- A. Peritonitis
 - B. * Phlegmon retroperitoneum space
 - C. Formation of pseudocysts
 - D. Development of saccharine diabetes
 - E. Intestinal impassability
654. What external signs are characteristic for the profuse bleeding from a gastric ulcer?
- A. Vomiting by the littlechanged blood, excrement of the raspberry colouring
 - B. * Vomiting by the littlechanged blood, tarry darkly-cherry chair
 - C. Vomiting by a complete mouth by dark blood with clots, black formed excrement
 - D. Vomiting on the type of "coffee-grounds", presence on the formed incandescence of strokes of red blood
 - E. Tarry darkly-cherry chair
655. What from operations does not execute at surgical treatment complicated acute pancreatitis:
- A. Through draining the stuffing-box bag
 - B. Abdominisation the pancreas
 - C. Omentopankreatopeksiy
 - D. Left-side resection of gland
 - E. * Pancreatojejunostomy
656. What from preparations has the expressed bacteriostatic action on Helicobacter pyloris
- A. * trichopol
 - B. Licviroton
 - C. oxiferiskorbon
 - D. atropine
 - E. pirinzsipin
657. What from the transferred diseases can be reason of the pseudoperitoneal syndrome?
- A. dissecting aneurysm of the abdominal part of aorta.
 - B. Extraperitoneal haematoma.
 - C. Nephrolithiasis, nephrocolic
 - D. Thrombosis the pelvis veins
 - E. * All transferred
658. What from the transferred operations does not belong to organ protective
- A. trunk vagotomy
 - B. * resection by Bilrot II
 - C. selective vagotomy
 - D. selective proximal vagotomy

- E. the all transferred does not belong
659. What from the transferred operations on the stomach organ protective is
- * selective proximal vagotomy
 - resection by Bilrot I
 - resection by Bilrot II
 - gastrectomy
 - all are transferred
660. What hormone of pancreas has influences on metabolism glucose:
- * Insulin
 - Vasopressin
 - Adrenalin
 - Somatotropin
 - Tiroksin
661. What hormone of pancreas has influences on the exchange of fats:
- Insulin
 - Glyukagon
 - * Lipocainu
 - Adrenalin
 - Somatotropin
662. What hormones undertake the protective operating on the mucous membrane of stomach, except for
- * ACTH
 - epidermal factor of growth
 - prostaglandin E
 - estrogens
 - STH
663. What is blood supply the body and tail pancreas:
- * Splenic artery
 - A.gastroduodenalis
 - A.gastrica sinistra
 - A.cystica
 - Variously
664. What is condition hematomesis at acute pancreatitis:
- Presence concomitant gastric ulcer
 - Presence concomitant gastritis
 - * Formation erosions in a stomach
 - Violation of microcirculation
 - Enzymes in blood
665. What is necrectomy:
- Delete the necrotic area within the limits of nonviable fabrics
 - * Delete the necrotic area within the limits of healthy fabrics
 - Delete part of organ with his transversal cutting within the limits of the changed fabrics
 - Total delete of organ
 - There is not a faithful answer
666. What is pancreas located in relation to a peritoneum:

- A. * Retroperitoneal
 - B. Mesoperitoneal
 - C. Intraperitoneal
 - D. All answers are incorrect
 - E. Variously
667. What is pancreatectomy:
- A. Delete the necrotic area within the limits of nonviable fabrics
 - B. Delete the necrotic area within the limits of healthy fabrics
 - C. Delete part of organ with his transversal cutting within the limits of the changed fabrics
 - D. * Total delete of organ
 - E. There is not a faithful answer
668. What is resection the pancreas:
- A. Delete the necrotic area within the limits of nonviable fabrics
 - B. Delete the necrotic area within the limits of healthy fabrics
 - C. * Delete part of organ with his transversal cutting within the limits of the changed fabrics
 - D. Total delete of organ
 - E. There is not a faithful answer
669. What is sequestrotomy:
- A. * Delete the necrotic area within the limits of nonviable fabrics
 - B. Delete the necrotic area within the limits of healthy fabrics
 - C. Delete part of organ with his transversal cutting within the limits of the changed fabrics
 - D. Total delete of organ
 - E. There is not a faithful answer
670. What level diastase answers a acute pancreatitis:
- A. 100-160
 - B. 200-500
 - C. * 600-1000
 - D. 1000-1500
 - E. 10-20
671. What level diastase answers a chronic pancreatitis:
- A. * 200-500
 - B. 100-160
 - C. 600-1000
 - D. 1000-1500
 - E. 10-20
672. What level diastase answers pancreonecrosis:
- A. 600-1000
 - B. 200-500
 - C. 100-160
 - D. * 1000-1500
 - E. 10-20
673. What localization of ulcer is most characteristic for the patients of elderly and senile age
- A. * cardial department of stomach
 - B. overhead third of gullet

- C. lower third of gullet
 - D. bulb of duodenum
 - E. small curvature
674. What method diagnostics the ulcerous illness most informing
- A. * esophagogastroduodenoscopy
 - B. analysis of excrement on the hidden blood
 - C. X-ray
 - D. global analysis of blood
 - E. research of gastric secretion
675. What method is it orientation possible to define the volume of hemorrhage on at the acute gastroenteric bleeding?
- A. On maintenance red corpuscles, haemoglobin, Ht, thrombocytes
 - B. On blood volume
 - C. * On an arteriotomy, pulse, state of patient
 - D. On a globular volume
 - E. On the level of thrombocytes
676. What most effective blocker secretion of pancreas at acute pancreatitis:
- A. Cyanocobalamin
 - B. Ubretid
 - C. Arginine
 - D. * Sandostatin
 - E. Benzogeksoniy
677. What most effective treatment the unformed complicated cyst is:
- A. Conservative treatment
 - B. * External draining cyst
 - C. Resection cyst within the limits of the unchanged gland
 - D. Cysticenterostomy
 - E. Cystogastrostomy
678. What most effective treatment the unformed uncomplicated cyst is:
- A. * Conservative treatment
 - B. External draining cyst
 - C. Resection cyst within the limits of the unchanged gland
 - D. Cysticenterostomy
 - E. Cystogastrostomy
679. What most optimum resort is which used for pathology the pancreas:
- A. Pyatigorsk
 - B. * Morshin
 - C. Kuyal'nik
 - D. Truskavets
 - E. Nemirov
680. What must be done in the case of development the posoperative peritonitis?
- A. to appoint antibiotics
 - B. to appoint anaesthetic
 - C. to execute laparocenthezis
 - D. to execute lasparoscopy
 - E. * to execute laparotomy

681. What norm diastase is:
- * To 160
 - To 50
 - To 200
 - To 300
 - To 1200
682. What operation is most often used for localization the formed pseudocyst in the area of tail the pancreas:
- Cystojejunostomy on the eliminated loop
 - External draining the cyst
 - Cystogastrostomy
 - * Cystoduodenostomy
 - Cystoenteroanastomosis
683. What operation is used for suppuration the pseudocysts of pancreas:
- Cystojejunostomy on the eliminated loop
 - * External draining the cyst
 - Cystogastrostomy
 - Cystoduodenostomy
 - Cystoenteroanastomosis
684. What operation is used for the pseudocyst of pancreas in the 3th stage of its forming:
- * Cystojejunostomy on the eliminated loop
 - External draining the cyst
 - Cystogastrostomy
 - Cystoduodenostomy
 - Cystoenteroanastomosis
685. What operation on a pancreas is indicated at the oedematous form the acute pancreatitis:
- * Interference on a pancreas is not needed
 - Pancreatectomy
 - Omentopankreatopeksy
 - Abdominisation pancreas
 - Marsupialization
686. What preparation does behave to blocker H2-retseptors?
- * tavegil
 - obzidan
 - hystdol
 - cerucal
 - oraza
687. What preparation does behave to blocker of muscarine receptors of coating cages?
- cymetidin
 - eglonin
 - * gastocepini
 - etimsiloli
 - vinilin
688. What preparation is applied at violation the extrasecretory function of pancreas at a chronic pancreatitis:
- Pyracetam
 - Papaverin

- C. Pantocrin
 - D. * Panzinorm
 - E. Panthenol
689. What preparation is applied at violation the extrasecretory function pancreas at a chronic pancreatitis:
- A. Pyracetam
 - B. Papaverin
 - C. Pantocrin
 - D. * Mezim-forte
 - E. Panthenol
690. What preparation is attributed to the proteases inhibitors:
- A. Tocopherol
 - B. Triampur
 - C. Tagamet
 - D. * Trasylol
 - E. Trypsin
691. What preparation is not attributed to the inhibitors proteases:
- A. Pantripin
 - B. Kontrikal
 - C. Gordox
 - D. Trasylol
 - E. * Trypsin
692. What preparations from the cytostatic group use for intensifying the chronic pancreatitis:
- A. Cyanocobalamin
 - B. Methyluracil
 - C. * 5-fluorouracil
 - D. Furadolizon
 - E. Mezimforte
693. What preparations, except for other properties, own yet and a bacteriostatic effect on *Helicobacter pyloris*
- A. * all are transferred preparations
 - B. Almagel
 - C. Vinylin
 - D. De-nol
 - E. Claritromycin
694. What primary purpose treatment the patient with fatty pancreatonecrosisto the operation is:
- A. Liquidations the pain
 - B. * Disintoxication the organism
 - C. Liquidations crampy the big duodenal papilla
 - D. Declines secretory activity the pancreas
 - E. Improvements microcirculation
695. What primary purpose treatment the patients with the heavy form of hemorrhagic pancreatonecrosis to the operation is:
- A. Liquidations the pain
 - B. * Disintoxication the organism
 - C. Liquidations crampy the big duodenal papilla
 - D. Declines secretory activity the pancreas

- E. Improvements microcirculation
696. What products are recommended in the diet of № 1?
- A. * hen in a steam kind
 - B. pancakes
 - C. raw egg-white
 - D. bread rye fresh
 - E. acute cheeses
697. What surgical pathology is a characteristic symptom of toxic «scissors» ?
- A. appendicitis
 - B. cholecystitis
 - C. pancreatitis
 - D. * peritonitis
 - E. mesadenitis
698. What symptom is most characteristic in the initial phase of peritonitis:
- A. sickliness and overhanding of pelvic peritoneum at rectal research.
 - B. dulling in declivous places at percussion of stomach
 - C. * tension of muscles the front abdominal wall.
 - D. swelling of stomach
 - E. melena
699. What syndrome is characteristic for hemorrhagic erosive gastritis?
- A. * ulcerous
 - B. hemorrhagic;
 - C. pain;
 - D. all answers are correct;
 - E. all answers are not correct.
700. What time urgent operations are executed at acute bleeding
- A. * 6 – 12 hours;
 - B. 6 – 10 hours;
 - C. 6 – 8 hours
 - D. 6 – 14 hours;
 - E. 6 – 20 hours
701. What type of peritonitis are fibrinogenous impositions at on a parietal and visceral peritoneum?
- A. at serosal.
 - B. at festering.
 - C. at fibrinogenous
 - D. at putrid.
 - E. * at all
702. What violation of mineral exchange is characteristic for patients with ulcerous illness of stomach and intestine
- A. hypocalcemia
 - B. * hypokaliemia
 - C. Hyponatremia
 - D. Hypercalcinemia
 - E. hyperkaliemia
703. When apply Teylor's method at ulcerous illness

- A. * at conservative treatment perforated ulcers
 - B. at conservative treatment sanguifluous ulcers
 - C. at conservative treatment penetration ulcers
 - D. at conservative treatment malignization ulcers
 - E. at conservative treatment of cicatrical pylorostenosis
704. Widespread festering peritonitis is investigation of all above-stated diseases, except for:
- A. perforative ulcers of duodenum
 - B. phlegmonous cholecystitis
 - C. * hydrocholecystiss
 - D. destructive pancreatitis
 - E. volvulus of sigmoid bowel
705. With what disease above all things is it necessary to differentiate the acute peritonitis?
- A. Hepar-kidney syndrome
 - B. * ischemic abdominal syndrome
 - C. adrenogenital syndrome
 - D. Horner's syndrome
 - E. diencephalic syndrome
706. A patient 2 hours ago fallen down from the first floor. State heavy. There are signs of the diffusive peritonitis. Survey sciagraphy of stomach is executed. What from roentgenologic symptoms diagnosis of break of cavernous organ will confirm?
- A. hight standings of diaphragm dome
 - B. Kloybers bowls
 - C. * free gas in an abdominal region
 - D. a free liquid in an abdominal region
 - E. infiltration in an abdominal region
707. A patient 2 hours ago got a blow in a stomach. Delivered in a urgent clinic in a grave condition with suspicion on the break of cavernous organ. What method of roentgenologic research will allow to specify a diagnosis?
- A. laparocentzis
 - B. laparoscopy
 - C. * sciagraphy of stomach
 - D. contrasting X-ray examination
 - E. irrigoscopy
708. A patient 40 years old, suffered ulcerous diseases of stomach. Last 2 days the pain became less intansive, but weakness and dizziness were appeare. Rose from a bed and lost consciousness. Pale. There are insignificant pains in epigastrium. It is
- A. Combination perforation with bleeding
 - B. Perforation
 - C. Malignization of ulcer
 - D. Stenosis of ulcer
 - E. * Gastroenteric bleeding
709. A patient 59 years old grumbles about permanent pains in an epigastrium, givings in the back, bad appetite, weakness, becoming thin. Pains appeared 3 months ago and in the beginning disturbed little, but grew gradually, during the last week there is vomiting, bringing a facilitation. Patient of the lowered feed, pale. The turgor of skin is lowered. A stomach is pulled in, palpation is sickly in an epigastrium, peripheral lymphonoduss are not megascopic. Roentgenologic is a defect of filling in area of back wall of pyloric department of stomach. At

a fibroscopy deep ulcer of back wall of stomach is with overpeering uneven edges. Possible complication

- A. malignization
- B. penetration, germination in surrounding organs
- C. perforation
- D. * stenosis
- E. bleeding

710. A patient delivered in a clinic with complaints about great pain after a breastbone and between shoulder-blades, arising up during the massive vomiting. A patient has low blood pressure, temperature is 39,5; leucocytosis - 20000. At x-ray photography research found the accumulation air and liquid in the left pleura cavity and mediastinum. Preliminary diagnosis

- A. * perforation of gullet
- B. subdiaphragmatic abscess
- C. acute pneumonia with the parapneumonic empyema of pleura
- D. perforation the gastric ulcer
- E. heart attack of myocardium

711. A patient entered urgent in a clinic on 3 days from the beginning of disease. The state is heavy, adynamic. Face of Hippocrates, pulse 138 in 1 min, AP - 8040. A stomach is blown away, moderato sickly at palpation. Shchotkin-Blyumbergs symptom is doubtful. A liquid is determined in the lower departments the stomach. A liquid, stinking excrement departs through gaping sphincter. That does explain the state of patient?

- A. intestinal impassability
- B. * diffusiv peritonitis
- C. mesenteric ischemia
- D. toxic dilatation of colon
- E. acute pancreatitis

712. A patient got the trauma of stomach 3 hours ago. Delivered in a urgent clinic with complaints about tormina. The lines of person are focus. Positive symptoms the irritation of peritoneum. At survey X-ray examination is found out free gas under the dome of diaphragm. A diagnosis is set: break of cavernous organ. What type of treatment is most expedient?

- A. cold on a stomach
- B. laparotsentez
- C. laparoscopy
- D. * operative
- E. antibiotic

713. A patient grumbles about great pain in a stomach, which arose up suddenly 6 hours ago. The diagnosis of peritonitis is set. What symptom is most characteristic for this diagnosis?

- A. increases of temperature
- B. tachycardia
- C. leucocytosis
- D. tension of muscles the abdominal wall
- E. * irritations of peritoneum

714. A patient suffers a stenocardia. Became ill suddenly after the physical loading. Complaints about pain in a epigastric area, which spread on the right half of stomach. Positive Shchotkin-Blyumbergs symptom. Rectal – overhang and painfulness the front wall of rectum. It is not discovered the free gas on the survey sciagram of stomach. What is most reliable diagnosis?

- A. abdominal form of heart attack the myocardium
- B. acute cholecystitis
- C. acute pancreatitis

- D. * peritonitis
 - E. peritonitis of apendicular character
715. A prophylaxis and treatment of postoperative enteroplegias at peritonitis is
- A. gastrotomy
 - B. gastrointestinotomy
 - C. * nasogastrointestinal intubation
 - D. intubation of abdominal region
 - E. intubation of stuffing-box bag
716. A stomach-ache develops suddenly at (complication of ulcerous illness)
- A. bleeding
 - B. malignization
 - C. stenosis
 - D. penetration
 - E. * perforations
717. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. * malignization ulcers
 - C. ulcerous anamnesis more than 10 years
 - D. heavy pain syndrome, proof heartburn
 - E. relapse ulcer after vagotomy
718. Absolute sign of unstable hemostasis
- A. * profluvium blood from a vessel;
 - B. absence blood in a stomach and bulb of duodenum;
 - C. presence light blood and faltungs of blood in a stomach;
 - D. all answers are correct;
 - E. all answers are not correct
719. Acute cholecystitis usually begins with
- A. Increases the temperature
 - B. Appearances the vomiting
 - C. * Pains under a rib on the right
 - D. Disorders of chair
 - E. Weights are in a epigastria area
720. Agents, which cause peritonitis, can be all except for:
- A. urines at the break of urinary bladder
 - B. tables of contents the stomach during the perforation of ulcer
 - C. to blood at the trauma of stomach
 - D. biles during the perforation of gall-bladder
 - E. * air in an abdominal region after laparoscopy research
721. All surgical interferences at the destructive forms of acute pancreatitis divide on:
- A. * Early, late, deferred operations
 - B. Primary, second, repeated operations
 - C. Invasion, not invasion operations
 - D. Complicated, operations are not complicated
 - E. Not divided
722. An intravenous cholecystography are indicated and informing at
- A. Gall-bladder is palpated

- B. To the icterus
 - C. Peritonitis
 - D. * Calming down attack of the acute cholecystitis
 - E. Cholangitis
723. Appearance „splashing sound” in acute intestinal obstruction is caused:
- A. * By the accumulation of liquid and gases in the afferent loop of intestine
 - B. By the accumulation of liquid and gases in the efferent loop of intestine
 - C. By the presence of liquid in the abdominal cavity
 - D. By the presence of free gas in the abdominal cavity
 - E. By the presence of free gas and liquid in the abdominal cavity
724. Aseptic inflammation of peritoneum can be caused:
- A. by a collibacillus
 - B. by staphylococuss
 - C. * by pancreatitis juice
 - D. by an abscess
 - E. by intestinal maintenance
725. At a perforation gastric ulcer, vomiting blood is
- A. often
 - B. very often
 - C. it is never
 - D. * rarely
 - E. there is not a right answer
726. At a subdiaphragmatic abscess in a clinical picture characteristically all following, except for:
- A. declines the respiratory excursion of lights.
 - B. high standing of diaphragm dome.
 - C. concord pleurisy.
 - D. basale atelectasis of lights.
 - E. * blood spitting
727. At a subhepatic abscess can take place all, except for:
- A. pains in a thorax with an irradiation in a supraclavicular area
 - B. reactive pleurisy
 - C. * Courvoisier's symptom
 - D. Senator's symptom
 - E. Dyushen's symptom
728. At an acute and chronic cholecystitis application is contra-indicated
- A. Omnoponum
 - B. * Morphine hydrochloride
 - C. No-spa
 - D. Atropine sulfate
 - E. Spazmalgon
729. At festering peritonitis the disorder of hemodynamics not conditioned:
- A. by the decline of volume the circulatory blood
 - B. * by the increase of volume the circulatory blood
 - C. by the decline of tone the vascular wall
 - D. by the change of properties the hemorheologys
 - E. by violation of cardiovascular activity

730. At localization the stone in a cystic channel and absence infection the phenomenon is carried by the name
- A. Courvoisier's symptom
 - B. Acute cholecystitis
 - C. Hydrocholecystis
 - D. * Cyst of gall-bladder
 - E. All answers are not right
731. At operations on a stomach sometimes by mistake bandage an additional hepatic artery, that, in same queue, can result to necrosis the segment, sectors or even stakes of liver. An additional hepatic artery more frequent walks away from an artery
- A. general hepatic
 - B. * left stomach
 - C. splenic
 - D. overhead mesenteric
 - E. all answers are faithful
732. At pancreatitis abscesses and infected necroses execute such operations, except for:
- A. Opening of abscess with draining
 - B. Pancreaticnecrsekvestrektomy
 - C. Pancreaticsekvestrektomy
 - D. Pancreaticsekvestrektomy with laparostomy
 - E. * Total pancreatotomy
733. At percussion in the first clock after perforation the ulcer more possibly
- A. * dulling in the gently sloping places of stomach
 - B. expansion of percussion border of liver
 - C. tympanitis in left subcosctal area
 - D. expansion of percussion border the spleen
 - E. there is not a right answer
734. At perforated ulcer the pulled wooden belly is determined in the stage of peritonitis
- A. * reactive
 - B. terminal
 - C. toxic
 - D. terminal-toxic
 - E. there is not a right answer
735. At peritonitis intestinal impassability develops, as a rule:
- A. mechanical
 - B. dynamic
 - C. spastic
 - D. * paralytic
 - E. mixed
736. At peritonitis of violation the proteometabolism characterized:
- A. by the increase of concentration the albumen
 - B. by the increase of concentration the globulins
 - C. diminishing of concentration the albumen
 - D. * diminishing of the albumen - globulins coefficient
 - E. by the increase of the albumen - globulins coefficient
737. At suspicion on a duodenal ulcer conduct above all things

- A. research of gastric secretion
 - B. * EGDS
 - C. X-ray examination organs of abdominal region
 - D. determination the level of gastrin the whey blood
 - E. cholecystography
738. At suspicion on a subdiaphragmatic abscess the followings methods of diagnostics are rotined, except for:
- A. * laparoscopy.
 - B. Sonography.
 - C. X-ray examination of thorax.
 - D. X-ray examination of abdominal region.
 - E. computer tomography
739. At suspicion on the abscess of Duglas space all followings methods of diagnostics are rotined, except for:
- A. rectal inspection.
 - B. * proctoscopy.
 - C. Sonography.
 - D. computer tomography.
 - E. vaginal research
740. At the perforate ulcer of duodenum used more frequent
- A. * sewing up of the perforate opening
 - B. sewing up + gastroenteroanastomosis
 - C. resection of stomach
 - D. resection of stomach for a shutdown
 - E. different types of vagotomy in combination with the economy resection of stomach and other draining operations
741. At ulcerous illness can a bleeding source be
- A. artery;
 - B. veins;
 - C. shallow vessels and ulcers;
 - D. all answers are not correct.
 - E. * all answers are correct
742. Atypical clinical motion of postoperative peritonitis is conditioned setting in a postoperative period:
- A. spasmolytic
 - B. anticoagulant
 - C. * anaesthetic
 - D. analeptics
 - E. cardiac
743. Basic method examination the patients with the uncomplicated cholecystitis
- A. Infusion cholegraphy
 - B. ERCP
 - C. * Sonography
 - D. Laparoskopy
 - E. Gastroduodenoscopy
744. Blood loos I stage characterized such indexes
- A. Ht 48-44, Hb 120

- B. Ht 23 and below, Hb 50 and below
 - C. Ht 31-23, Hb 80
 - D. * Ht 38-32, Hb 100
 - E. Ht 44-40, Hb 110 /?
745. Blood loos II stage characterized
- A. * Ht 23 and below, Hb 50 and below
 - B. Ht 31-23, Hb 80
 - C. Ht 44-40, Hb 110
 - D. Ht 48-44, Hb 120
 - E. Ht 48-50, Hb 130
746. Blood loos III stage characterized a degree such indexes
- A. * Ht 31-23, Hb 80
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 38-32, Hb 100
 - D. Ht 44-40, Hb 110
 - E. Ht 48-44, Hb 120
747. Can not stipulate a mechanical icterus
- A. Cancer the head of pancreas
 - B. * Stone of cystic channel
 - C. Chronic pancreatitis
 - D. Stone the general bilious channel
 - E. Tumour large duodenal papilla
748. Change in the analysis of blood at a perforete ulcer
- A. leucopenia
 - B. anaemia
 - C. eosinophilia
 - D. * leucocytosis with a neutrophilic change
 - E. there is not a right answer
749. Characteristic laboratory sign of the acute uncomplicated cholecystitis
- A. Diastasuria
 - B. * Leykocytosis
 - C. Hypoglycemia
 - D. Glucosuria
 - E. Hyperbillirubinemia
750. Conservative treatment of intestinal obstruction is indicated in all cases, except for:
- A. * Torsion
 - B. Spastic obstruction
 - C. Paralytic obstruction
 - D. Coprostasis
 - E. There is no right answer
751. Courvoisier's symptom is
- A. Painless megascopic gall-bladder, patient is not yellow
 - B. Sickly megascopic gall-bladder, patient is not yellow
 - C. * Painless megascopic gall-bladder, patient is yellow
 - D. A gall-bladder don't palpaton
 - E. All answers are not right

752. Decision role in differential diagnostics of peritonitis and acute vascular purpura is a symptom:
- A. * hemorrhagic rash on a skin
 - B. acute pain in a stomach
 - C. systole noise above the abdominal department of aorta
 - D. absence of pulsation of abdominal department of aorta
 - E. melena at rectal research
753. Decision role in differential diagnostics of peritonitis and break the bone of pelvis is:
- A. to appoint antibiotics
 - B. to appoint anaesthetic
 - C. to execute laparocenthezis
 - D. * to execute laparoscopy
 - E. to execute survey sciagraphy of abdominal region
754. Decision role in differential diagnostics the peritonitis and dissecting aneurysm of aorta , there is a symptom:
- A. aperistalsis
 - B. acute pain in a stomach
 - C. * systole noise above the abdominal department of aorta
 - D. absence of pulsation of abdominal department of aorta
 - E. melena at rectal research
755. Dehidratation of the organism in acute intestinal obstruction most rapidly develops in:
- A. * Torsion of small intestine
 - B. Torsion of sygmoid intestine
 - C. Tumours of rectum with the phenomena of obstruction
 - D. Obturation large intestinal obstruction
 - E. Ileocaecal invagination
756. Diet at bleeding gastric and duodenum ulcers
- A. * Meulengracht's
 - B. 1 by Pevznerom
 - C. 5 by Pevznerom
 - D. 15 by Pevznerom
 - E. 7 by Pevznerom
757. Diffusive festering peritonitis can be investigation of all transferred diseases, except for:
- A. perforations Meckel's diverticulum
 - B. destructive appendicitis
 - C. * stenosis of large duodenal nipple
 - D. Richter strangulation of hernia
 - E. acute intestinal impassability
758. Direct sign of ulcer at x-ray research
- A. violation of evacuation from a stomach
 - B. change of tone of stomach
 - C. form the stomach as "sand-glasses"
 - D. * symptom of "niche"
 - E. defect of filling
759. Disappearance or diminishing the pain with beginning of bleeding from an ulcer is
- A. * Bergman's sing
 - B. Spazarskiy's sing

- C. Mendel's suing
 - D. De Keven's sing
 - E. Eleker's sing
760. Draining the abdominal region is conducted at:
- A. phlegmonous appendicitis without exudation
 - B. * gangrenous appendicitis with exudation
 - C. phlegmonous appendicitis with serosal exudation odourless
 - D. there is not a right answer
 - E. catarrhal appendicitis
761. Duration the period of primary shock at a perforated ulcer
- A. * 3-6 hours
 - B. 6-12 hours
 - C. 1-3 hours
 - D. 12-24 hours
 - E. 24-36 hours
762. During the examination of patient with acute intestinal obstruction: the Zege-Maitenphel's and "Obuhov's hospital" symptoms are positive. What type of obstruction it is characteristic for?
- A. * Sigmoid intestine torsion
 - B. Ileocaecal invagination
 - C. Obturation by the tumour of ascending intestine
 - D. Torsion of small intestine
 - E. All mentioned is correct
763. Esophagogastroduodenoscopy can find out next changes in a stomach, except for
- A. tumours
 - B. ulcers
 - C. bleeding polypuses
 - D. erosions
 - E. * changes of evacuation function
764. Fibrinogenous impositions on a peritoneum are not at peritonitis:
- A. * serosal
 - B. fibrinogenous
 - C. festering
 - D. putrid
 - E. excrement
765. For a patient 35 years old "knife-like pain" in an epigastrium, appearing suddenly hour back. Pale, pulse is 50, T-36,9 °C. A stomach is tense, as a board. In anamnesis an ulcer of duodenum is during 5 years. Complication came
- A. malignization
 - B. stenosis
 - C. penetration
 - D. * perforation
 - E. bleeding
766. For a patient, suffering ulcerous illness, sudden great pain in an epigastrium and unclear symptoms of peritonitis appeared. During subsequent days the display of these symptoms diminished, the state of patient had become better. It is possible to suppose at such clinic
- A. typical perforation the ulcer

- B. * covered perforation
 - C. preperforative state
 - D. intensifying of ulcerous illness
 - E. there is not a right answer
767. For a perforation declivous organ all is characteristic in a free abdominal region, except for:
- A. acute began pains.
 - B. wooden belly.
 - C. collapse.
 - D. * oliguria.
 - E. tachycardia.
768. For a perforate gastric ulcer in the first six clock typical
- A. great sudden pains in a stomach, frequent vomiting, swelling of stomach, disappearance the hepatic dullness, "sickle" under the right dome of diaphragm
 - B. frequent vomiting, swelling of stomach, disappearance the hepatic dullness, "sickle" under the right dome of diaphragm
 - C. great sudden pains in a stomach, wooden belly, swelling of stomach
 - D. * great sudden pains in a stomach, wooden belly, disappearance the hepatic dullness, "sickle" under the right dome of diaphragm
 - E. combinations of signs are equivalent
769. For acute intestinal obstruction the followings types of operations are possible, except for:
- A. * Gastrostomy
 - B. Right-side hemicolectomy
 - C. Resections of intestine
 - D. Colostomy
 - E. Hartmann's operation
770. For bleeding ulcer characteristic sign is
- A. * pain in an epigastrium;
 - B. knife-like pain;
 - C. signs irritation of peritoneum;
 - D. presence fresh blood in incandescence
 - E. melena;
771. For bleeding ulcer characteristically
- A. * melena
 - B. tension the muscles of front abdominal wall
 - C. Spazarskiy's sign
 - D. sickliness the back vault of vagina
 - E. irradiation pain in a shoulder or shoulder-blade
772. For clarification character of the icterus and reason of it development is necessary to make:
- A. X-ray examination of the subhepatic space, infusion cholecystography, ERCP
 - B. Sonography, ERCP
 - C. Infusion cholecystography, ERCP
 - D. * Sonography, infusion cholecystography, ERCP
 - E. ERCP
773. For clarification diagnosis of perforate ulcer used
- A. Gastroscopy
 - B. X-ray of abdominal region
 - C. * X-ray of abdominal region, after gastroscopy, then X-ray of abdominal region

- D. CT
 - E. There is not a right answer
774. For differentiation of acute appendicitis with the covered perforate ulcer useful
- A. gastroduodenoscopy, X-ray of abdominal region, laparoscopy
 - B. gastroduodenoscopy, X-ray of abdominal region, Sonography of abdominal region
 - C. survey X-ray of abdominal region, Sonography of abdominal region, irrigoscopy
 - D. X-ray of abdominal region, irrigoscopy
 - E. * X-ray of abdominal region, laparoscopy
775. For intestinal obstruction caused by invagination is characteristic:
- A. * Bloody discharges from rectum
 - B. The wave-like abdominal pain
 - C. Tumorous formation in a right iliac area by palpation
 - D. Bolus-like feces
 - E. Atony of rectal sphincter
776. For motion of disease ulcerous illness of middle weight characteristically
- A. development of complications
 - B. * relapses 1-2 times per a year
 - C. 4 and anymore relapses on a year
 - D. 5 and more relapses are on a year
 - E. 3 and anymore relapses on a year
777. For paralytic intestinal obstruction is characteristic:
- A. * Delay of stool and gases and acute distension of abdomen
 - B. Asymmetry of abdomen
 - C. The expressed wave-like pain in the abdominal cavity
 - D. Zege-Maitenphel's sign
 - E. Effusion in the abdominal cavity
778. For perforative appendicitis characteristically
- A. tension the muscles of front abdominal wall
 - B. there is the sudden strengthening of stomach-aches
 - C. rapid growth of clinical picture the peritonitis
 - D. Razdolskuy's symptom
 - E. * all transferred
779. For perforated ulcer characteristically
- A. * tension the muscles of front abdominal wall
 - B. melena
 - C. vomiting by coffee-grounds
 - D. high intestinal impassability
 - E. vomiting stagnant gastric maintenance
780. For peritonitis in the first 24 hours not typical
- A. aperistalsis intestine
 - B. * Kullenkamp's symptom
 - C. Tachycardia
 - D. dry language
 - E. tension the muscles of abdominal wall and positive Shchetkin-Blyumberg's symptom
781. For peritonitis there is a not characteristic symptom:
- A. Shchetkin-Blyumberg's symptom

- B. Voskresenskiy's symptom
 - C. Kulenkampf's symptom
 - D. * Moebius's symptom
 - E. Krymov's symptom
782. For pneumoperitoneum is characteristic symptom
- A. * Zhober's;
 - B. Khelatid's;
 - C. Podlag's;
 - D. Vigats's;
 - E. Udin's.
783. For the heavy flow of ulcerous illness characteristically
- A. * development of complications
 - B. seasonal exacerbation more not frequent 1-2 times per a year
 - C. 1-2 relapse on a year
 - D. liquid, but protracted exacerbation
 - E. exacerbation duration more than 10 days
784. For the high small intestinal obstruction is not characteristic:
- A. * Zege-Maitenphel's sign
 - B. The wave-like abdominal pain
 - C. Splashing sound" (Sklyarov's sign)
 - D. Multiple vomiting
 - E. Cloyber's cups on X-ray
785. For the late stage of peritonitis all is characteristic, except for:
- A. swelling of stomach
 - B. hypovolemia
 - C. disappearance of intestinal noises
 - D. hypoproteinemia
 - E. * increased peristalsis
786. For the low large intestinal obstruction all is characteristic, except for:
- A. * Rapid dehydration
 - B. Delay of stool
 - C. Appearances of Cloyber's cups
 - D. Gradual progression of symptoms
 - E. Abdominal distension
787. For the reactive stage of festering peritonitis not characteristically:
- A. acute sickliness the stomach at palpation
 - B. positive Shchetkin-Blyumberg's symptom
 - C. tension of muscles the front abdominal wall
 - D. * face of «Hippocrates»
 - E. tachycardia
788. For the terminal stage of peritonitis not characteristically:
- A. tachycardia
 - B. * bradycardia
 - C. hyperthermia
 - D. falling of arteriotony
 - E. dynamic intestinal impassability

789. For the treatment measures in obturation intestinal obstruction all mentioned belong, except:
- A. * Prescribing of medicines which increase intestinal peristalsis
 - B. Prescribing of spasmolytics
 - C. Performing of siphon enema
 - D. Introducing of nasogastral tube for intestinal decompression
 - E. Corrections of water-electrolytes disturbances
790. For what purpose in treatment of diffusive festering peritonitis does execute nasointestinal intubation?
- A. account of losses the liquid through a gastroenteric highway.
 - B. control of electrolyte composition the intestinal maintenance
 - C. * prophylaxis of intestinal impassability
 - D. stimulation of the intestinal peristalsis
 - E. suppression of the intestinal peristalsis
791. From what department degestive tract developmentp more frequent than all the bleeding at the Mallory-Weiss syndrome
- A. gastric fundus
 - B. * cardial pert;
 - C. pyloric department;
 - D. from duodenal;
 - E. from a thick intestine
792. Giant ulcer is an ulcer measuring
- A. over 4,5 cm
 - B. * over 3 cm
 - C. over 4 cm
 - D. over 5 cm
 - E. over 3,5 cm
793. Hectic fever is possible at
- A. the uncomplicated ulcer
 - B. bleeding from an ulcer
 - C. perforations of ulcer in the first clock
 - D. * penetration
 - E. cicatrice-ulcerous stenosis
794. Hemobilia is
- A. * all answers are correct;
 - B. bleeding the bilious ways and liver;
 - C. bleeding the general bilious channel;
 - D. bloody clot in the big duodenal papilla;
 - E. all answers are not correct.
795. Hepatic dullness is not determined at
- A. break of spleen
 - B. * perforations of gastric ulcer
 - C. break of bud
 - D. volvulus of stomach
 - E. mesenterial ishemia
796. How is the diagnosis of the general peritonitis set to the operation?
- A. roentgenologic
 - B. anamnestic

- C. by laboratory determination the signs of inflammatory reaction
 - D. * on clinical signs
 - E. on the level secretion the gastric juice
797. In a patient with pains in a epigastric area, what was displaced from a right iliac area. There was nausea and single vomiting. A patient accepted an analgin and put a hot-water bottle to the stomach, pains calmed down whereupon. On 2 days pains recommenced, spread on all stomach, the frequent vomiting appeared. The state of patient is heavy. Consciousness entangled. Euphoria. Pulse 128 in min, AP - 95/60. Language is dry. A stomach is tense in all departments. Temperature 37,2. Leucocytes in blood of 18? 109/l. Diagnosis
- A. * acute appendicitis, terminal stage of peritonitis
 - B. typhoid, perforation of typhoidal ulcer
 - C. perforation gastric ulcer
 - D. gastric bleeding
 - E. there is not a right answer
798. In a patient, suffering ulcerous illness, sudden great pain in an epigastrium and unclear symptoms of peritonitis appeared. During subsequent days the display of these symptoms diminished, the state of patient had become better. It is possible to suppose at such clinic
- A. typical perforation of ulcer
 - B. * covered perforation
 - C. preperforete state
 - D. intensifying the ulcerous illness
 - E. there is not a right answer
799. In an induction centre the sick is delivered with the attacks of cramps. Many years suffers ulcerous illness. Lately the daily vomiting appeared practically by the eaten food. Exhausted, in a эпигастральной area pigmentation of skin. A capotement is determined. Diagnosis
- A. malignization
 - B. bleeding
 - C. * stenosis
 - D. perforation
 - E. penetration
800. In classic motion of peritonitis select the stages:
- A. early, intermediate, late
 - B. reactive, intermediate, late
 - C. toxic, intoxication, terminal
 - D. * reactive, toxic, terminal
 - E. reactive, toxic, late
801. In patient of 82 years old with acute intestinal obstruction caused by the tumour of sigmoid intestine, who entered in late terms, the most rational tactic of treatment is the following:
- A. * Preparing for the operation during 2-3 hours with following performance of Hartmann's operation
 - B. Examination and performance of operation in 48-72 hours
 - C. Only conservative therapy
 - D. Infusion therapy and repeated siphon enemas
 - E. Urgent operation with performance of sigmoid intestine resection and anastomosis "end to end"
802. In the dynamics of acute peritonitis it is necessary positive to consider
- A. * decline of amount the leucocytes
 - B. increase of amount the leucocytes

- C. leucocytosis with the change of leukocytic formula to the left
 - D. growth of the leukocytic index intoxication
 - E. leukopenia
803. In the moment of perforation the gastric or duodenum ulcer meets most often
- A. * suddenly arising up megalgia
 - B. cramp-like pain
 - C. noncommunicative, moderate pain
 - D. liquid chair
 - E. tachycardia
804. In treatment of the diffusive peritonitis of appendicitis origin a basic value has
- A. correction water-electrolyte violations
 - B. sanitization of abdominal region
 - C. removal the source of peritonitis
 - D. * all answers are faithful
 - E. antibacterial therapy
805. In treatment of ulcerous illness the stomach and duodenum executed only on urgent indications
- A. stomach resection by Bilrot-II
 - B. * sewing up of the perforate opening
 - C. selective-proximal vagotomy
 - D. trunk vagotomy with a pyloroplasty
 - E. stomach resection by Bilrot-I
806. In what area of stomach practically never is not origin of ulcers, or it is extraordinarily rarely?
- A. small curvature of stomach;
 - B. back wall of stomach, nearer to small curvature;
 - C. large curvature of stomach
 - D. * cardiac part of stomach;
 - E. pylorus.
807. In what type of intestinal obstruction one of the symptom is the red water after a cleaning enema:
- A. * Intestinal infarction
 - B. Paralytic
 - C. Spastic
 - D. Torsion of small intestine
 - E. Invagination
808. In what type of intestinal obstruction one of the symptom will be a blood discharge from rectum:
- A. * Invagination
 - B. Paralytic
 - C. Spastic
 - D. Torsion of small intestine
 - E. Intestinal infarction
809. In what vein is a venous outflow carried out in from a stomach?
- A. * V. Portae;
 - B. V. odd;
 - C. V. pair;

- D. V. overhead hollow;
 - E. V. lower hollow;
810. Indication to early operative interference at acute pancreatitis is:
- A. Acute pancreatolysis
 - B. Acute oedematous pancreatitis
 - C. * Progressive multiple organ failure what not added conservative therapy during 48-72 hours
 - D. Acute fatty pancreatitis
 - E. Forming of pseudocyst
811. Indications to special intraoperative examination bilious ways
- A. * A cholangitis, expansion of the common bile duct, plural shallow concrements in a gall-bladder, mechanical icterus in anamnesis
 - B. Cholangitis, expansion of the common bile duct, plural shallow concrements in a gall-bladder
 - C. Expansion of the common bile duct, icterus in the moment of operation, plural shallow concrements in a gall-bladder
 - D. Expansion of the common bile duct, mechanical icterus in anamnesis
 - E. All right
812. Intraoperative cholangiography at cholecystectomy used for
- A. Researches of peristalsis the general bilious channel
 - B. Retrograde filling of intrahepatic bilious channels
 - C. Researches tone the sphincter Oddi
 - D. * Exceptions concrements in channels
 - E. Exposures cholangitis
813. Laparostomy at the diffusive peritonitis used with a purpose
- A. * to repeated sanitization the abdominal region
 - B. extracorporal dialysis
 - C. hemosorption
 - D. laparoscopy
 - E. stimulations the peristalsis
814. Large intestine obstruction is more frequently caused:
- A. * By the malignant tumours of intestine
 - B. Foreign bodies
 - C. By the adhesions of abdominal cavity
 - D. By gall-stones
 - E. Helminths
815. Large ulcer is an ulcer measuring
- A. 1-4 cm
 - B. 1-3 cm
 - C. 3-5 cm
 - D. 2- 6 cm
 - E. * 2-3 cm
816. Least answers a subhepatic abscess:
- A. Senator's symptom
 - B. Dyushen's symptom
 - C. Liten's symptom
 - D. * Rovzing's symptom

- E. Shchotkin-Blyumberg's symptom
817. Middle laparotomy must be conducted at:
- * diffusive peritonitis
 - local unlimited peritonitis
 - abscess of Douglas space
 - periappendiceal infiltration
 - acute appendicitis
818. Most frequent reason of peritonitis
- posoperative complication
 - acute trauma of stomach
 - acute cholecystitis
 - * acute appendicitis
 - acute intestinal impassability
819. Most guarantee against the recedive of ulcer during an operation concerning ulcerous diseases of duodenum gives
- selective-proximal vagotomy
 - trunks vagotomy with a pyloroplasty
 - * resection no less than a 2/3 stomach
 - antrumectomy with selective vagotomy
 - veritable antrumectomy
820. Most informing method diagnostics the perforate ulcers
- X-ray examination
 - Sonography
 - EGDS
 - * laparoscopy
 - laparocentezis
821. 116. Most widespread laparoscopic operation at bile-stone illness:
- Cholecystectomy with revision the bilious ways
 - Ideal cholecysectomy
 - * Choledoholitotomy
 - Cholecystectomy
 - All answers are right
822. Name the most important method of investigation in the diagnostic of „acute intestinal obstruction“:
- * Research of barium passage trough intestine
 - Plain X-ray of abdominal cavity
 - Fibrogastroduodenoscopy
 - Laparoscopy
 - Biochemical blood analysis
823. Normal width of the common bile duct
- To 0,4 cm
 - * 0,5-0,7 cm
 - 0,8-1,3 cm
 - 1,4-2,0 cm
 - Over 2,0 cm
824. Numbers of complications the ulcerous illness

- A. * 5
 - B. 4
 - C. 1
 - D. 3
 - E. 2
825. Pain in the left shoulder can be rather at
- A. acute cholecystitis
 - B. perforations the ulcer of duodenum
 - C. * perforations the gastric ulcer
 - D. mesenteric lymphadenitis
 - E. there is not a right answer
826. Patient which the gastroenteric bleeding in house is necessary
- A. * To send a patient in surgical permanent establishment
 - B. To appoint rest, enter Cacl, vicasol
 - C. To wash a stomach, appoint a cold, rest of supervision
 - D. To send a patient in a therapeutic gastroenterology separation
 - E. A right answer absents
827. Patient with a gangrenous cholecystitis is indicating:
- A. * Urgent operation
 - B. Operation at default of effect from conservative therapy
 - C. Conservative treatment
 - D. Deferred operation
 - E. A decision-making depends on age of patient
828. Penetration of gastric content in an abdominal region possibly at
- A. bleeding
 - B. stenosis
 - C. penetration
 - D. malignixation
 - E. * perforations
829. Peritonitis does not develop at the next form of acute appendicitis
- A. * catarrhal
 - B. phlegmonous
 - C. gangrenous
 - D. perforatiove
 - E. gangrenous-perforatiove
830. Postoperative peritonitis is characterized a flow:
- A. typical
 - B. * atypical
 - C. stormy
 - D. with the expressed pain reaction
 - E. with the expressed intoxication
831. Preoperated complication of acute appendicitis
- A. * diffusive peritonitis
 - B. intra-abdominal bleeding
 - C. suppuration of wound
 - D. evisceration wounds
 - E. there are not a right answer

832. Preoperative preparation for patients from peritonitis does not provide:
- A. corrections the violations cardiovascular system
 - B. * laparocentzis
 - C. declines the intoxication
 - D. corrections the exchange violations
 - E. struggle with hy hypovolemia
833. Rational operation at the subcompensated ulcerous stenosis of pylorus
- A. antrumectomy
 - B. * resection 2/3 stomach
 - C. front gastroenteroanastomosis
 - D. gastrectomy
 - E. selective proximal vagotomy
834. Relaparotomy at difuusive festering peritonitis pursues:
- A. * repeated revision of abdominal region
 - B. repeated laparoscopy of abdominal region
 - C. repeated endoscopy of abdominal region
 - D. normalization the function of gall-bladder
 - E. normalization the function of urinary bladder
835. Relative absolute indication to operative treatment ulcerous illness is
- A. * penetration of ulcer
 - B. ulcerous anamnesis more than 15 years
 - C. malignization ulcers
 - D. perforation of ulcer
 - E. relapses more than 3 times per a year
836. Specific symptom of perforation declivous organ in a free abdominal region is:
- A. high leucocytosis.
 - B. absence of intestinal noises.
 - C. * pneumoperitoneum.
 - D. positive symptoms of irritation the peritoneum.
 - E. dulling of the percussion sound in the gently sloping places of abdominal region
837. Specify a criterion which grounds the choice of middle laoarotomy access at the deffusion festering peritonitis:
- A. minimum trauma the abdominal wall
 - B. minimum cut
 - C. * valuable revision the abdominal region.
 - D. minimum blood loss.
 - E. minimum level of infecting the wound
838. Specify obligatory measures which are conducted during an operation concerning widespread fibrinopurulent peritonitis:
- A. removal the source of peritonitis.
 - B. sanitization of the abdominal region.
 - C. decompression of intestine.
 - D. draining of abdominal region.
 - E. * all answers are faithful
839. Specify possible reasons of the pseudoperitoneal syndrome:
- A. uremia.

- B. porphyria.
 - C. diabetic crisis.
 - D. nephrocolic.
 - E. * all transferred
840. Specify reason of use the derivatives of metronidasoli as an obligatory component of antibacterial therapy of widespread peritonitis?
- A. * removal of anaerobic microflora.
 - B. removal of mycotic flora.
 - C. removal of microflora of aerobic.
 - D. prophylaxis of intestinal worm invasion.
 - E. prophylaxis of widespread candidosis
841. Specify the most rational way the introduction of antibacterial preparations in treatment of diffusive festering peritonitis:
- A. peroral
 - B. hypodermic
 - C. intramuscular
 - D. * intravenous
 - E. intraperitoneal
842. Sudden and painful pain with localization in the middle departments of stomach with an irradiation in the back more characteristic for
- A. heart attack the myocardium
 - B. * break aneurysm the aorta
 - C. bilious colic
 - D. perforate ulcers
 - E. nephrocolic
843. Symptom of the toxic «scissors» at peritonitis it:
- A. increase of temperature and pulse
 - B. diminishing of temperature and pulse
 - C. * diminishing of temperature and increase of pulse
 - D. increase of temperature and diminishing of pulse
 - E. increase of temperature and diminishing of breathing frequency
844. Symptom of toxic «scissors» at the peritinitis it is correlation:
- A. * pulse and temperature
 - B. arteriotony and pulse
 - C. arteriotony and temperature
 - D. rectal and axillar temperature
 - E. rate breathings and temperatures
845. Tactic of family doctor during the covered perforation of ulcer
- A. * urgent hospitalization in surgical permanent establishment
 - B. planned hospitalization in surgical permanent establishment
 - C. supervision on to the house
 - D. hospitalization in therapeutic permanent establishment
 - E. there is not a right answer
846. Tactic of surgeon at periappendiceal mas:
- A. operative treatment
 - B. * conservative treatment, systematic looking after a patient
 - C. there is not a right answer

- D. supervision
 - E. puncture
847. Tension of abdominal wall and stage peritonitis at acute appendicitis
- A. * absents, a stomach is swollen - terminal
 - B. absents, a stomach is not swollen - terminal
 - C. expressed, a stomach is not swollen - terminal
 - D. absents, a stomach is swollen - toxic
 - E. absents, a stomach is swollen – initial
848. Tension of muscles the right iliac area at the perforation of duodenal ulcer is explained
- A. by development of the diffusive peritonitis
 - B. by reflex connections through medullispinal nerves
 - C. * flowing down of gastric content in a right lateral channel
 - D. entering of air abdominal region
 - E. viscerovisceral connections with a vermicular appendix
849. Tension the muscles of stomach in an initial period of perforation ulcer
- A. absents
 - B. * visible
 - C. sickliness under the left shoulder-blade
 - D. appears at palpation
 - E. there is not a right answer
850. The attack of hepatic (bilious) colic development
- A. * Suddenly, acutely
 - B. After a initial period
 - C. Gradually, gradually
 - D. After the protracted starvation
 - E. After supercooling
851. The best variant the treatment of subhepatic abscess is:
- A. conservative treatment
 - B. extra-peritoneal section and draining
 - C. laparotomy, section and tamponing of cavity
 - D. * puncture of abscess by a thick needle under control Sonography
 - E. all transferred right
852. The complex treatment of festering peritonitis does not provide for:
- A. delete of primary hearth
 - B. * vagotomy
 - C. correction the metabolic violations
 - D. adequate therapy by antibiotics
 - E. struggle of paresis the intestine
853. The development of paralytic intestinal obstruction is caused by all mentioned except for:
- A. * Leaden poisoning
 - B. Peritonitis
 - C. Acute pancreatitis
 - D. Retroperitoneal hematoma
 - E. Disorders of mesenterial circulation of blood
854. The diagnostic measures which immediately performed in suspicion on acute intestinal obstruction include everything, except:

- A. * Angiography of abdominal cavity
 - B. Auscultation of abdomen
 - C. Plain X-ray of abdominal cavity
 - D. Introducing of nasogastal tube for the decompression of intestine
 - E. Palpation of abdomen, digital examination of rectum
855. The diagnostics criteria of the anaerobic peritonitis is
- A. stormy progress of disease
 - B. heavy festering intoxication
 - C. expressed enteroplegia
 - D. abundant amount of exsudate green-brown colors
 - E. * all is transferred
856. The exsudate painted blood in an abdominal region is observed always, except for:
- A. * tubercular peritonitis
 - B. violations of extra-uterine pregnancy
 - C. mesenteric ischemia
 - D. acute pancreatitis
 - E. twisted oothecoma
857. The favourable result of treatment the patients with peritonitis provide:
- A. early surgical interference
 - B. adequate operation
 - C. intravenous antibacterial therapy
 - D. methods of extracorporeal dialysis
 - E. * all is transferred
858. The index litogenic bile is determined correlation
- A. Cholesterol, billirubine and lecithin
 - B. Billirubine, bilious acids and lecithin
 - C. Cholesterol, bilious acids and bilirubine
 - D. * Cholesterol, bilious acids and lecithin
 - E. Billirubine and lecithin
859. The leading symptom of peritonitis is:
- A. stomach-ache
 - B. enteroplegia
 - C. swelling of stomach
 - D. * symptoms the irritation of peritoneum
 - E. symptoms of the intestinal impassability
860. The liquid painted a bile in an abdominal region is not observed at
- A. * Break pus hydatidoma
 - B. To the protracted mechanical icterus
 - C. Spontaneous bilious peritonitis
 - D. Perforations of gall-bladder
 - E. Perforations the ulcer of duodenum
861. The methods of disintoxication at peritonitis are not:
- A. lymphosorbtion
 - B. hemosorption
 - C. enterosorbtion
 - D. plasmapheresis
 - E. * antibiotic

862. The most frequent cause of small intestine mechanical obstruction is:
- * Adhesions of abdominal cavity
 - Gall-stones
 - Foreign bodies
 - Tumours
 - Helmints
863. The most informing method the instrumental diagnostics of peritonitis is:
- * survey sciagraphy of abdominal region
 - lasparoscopy
 - angiography
 - gastroscopy
 - colonoscopy
864. The patient of 62 years old grumbles about a weakness, fatigue ability, sometimes moderate pains and sense of weight in an anticardium, vomiting after-meal. Sick about 6 months. The pallor of skin covers, sickliness and compression is marked in a epigastric area, a reaction with a benzidine is acutely positive, haemoglobin is 52 g/l, eras. 2,5. At x-ray research pyloric department of stomach the defect of filling is determined 3x2 cm, displaced at palpation.
- Complication
- * bleeding, anaemia
 - stenosis
 - penetration, germination in surrounding organs
 - perforation
 - malignization
865. The sign of the diffusive peritonitis is not
- * visible peristalsis
 - absence the peristaltic intestinal noises
 - sickliness of stomach at palpation in all departments
 - even tension the muscles of front abdominal wall
 - positive Shchetkin-Blyumberg's symptom
866. The special research extrahepatic bilious ways is absolutely indicated at:
- Shallow stone in common bile duct, suspicion on stenosis the large duodenal papilla, expansion of the common bile duct, mechanical icterus in the moment of operation
 - Suspicion on stenosis of large duodenal papilla, expansion of the common bile duct, mechanical icterus in the moment of operation
 - At expansion of the common bile duct
 - * All right
 - All not right
867. The ways distribution of gastroenteric content during the perforation of ulcer depend on
- anatomic structure of the lateral ductings
 - locations of stomach
 - localizations of the perforate opening
 - * only transferred
 - forms and locations of transversal rim bowel
868. There is vomiting at peritonitis, as a rule:
- single
 - episodic
 - * frequent

- D. abundant
 - E. scanty
869. To absolute indication to operative interference at ulcerous illness does not belong
- A. * scarry-ulcerous stenosis
 - B. perforation of ulcer
 - C. profuse bleeding
 - D. diameter ulcer a more than 3 cm
 - E. bleeding what does not stopped with conservative
870. To determine the viability of strangulated intestine it is necessary to be oriented on the followings signs, except:
- A. * Presence of strangulation groove
 - B. Color of intestine
 - C. Presence of peristalsis
 - D. The pulsation of mesenteric vessels
 - E. All answers are incorrect
871. To the gastric – intestinal bleeding of un ulcerous etiology belong
- A. * Mallory-Weiss syndrome;
 - B. hemorrhagic erosive gastritis;
 - C. diseases by Randyu – Oslera – Vebera;
 - D. Menetrie's sing;
 - E. all answers are correct.
872. To the initial phase the peritonitis of appendicle origin does not behave
- A. sickliness the pelvic peritoneum at rectal research
 - B. tachycardia
 - C. * noticeable electrolyte changes
 - D. tendency to growth leucocytosis
 - E. tension of muscles the abdominal wall
873. To the late stage of peritonitis of appendicle origin does not behave
- A. dehydration
 - B. swelling of stomach
 - C. * increased peristalsis
 - D. hypoproteinemia
 - E. disappearance of intestinal noises
874. To the local isolated peritonitis does not attribute:
- A. subdiaphragmatic abscess
 - B. subhepatic abscess
 - C. interintestinal abscess
 - D. * primary idiopathic peritonitis
 - E. abscess cystic-rectal spaces
875. Udin's sing at a perforated ulcer is
- A. * feeling at palpation shove the gases which penetrate through the perforated opening
 - B. dulling perforated sound in the lateral departments of stomach
 - C. disappearance of hepatic dullness
 - D. irradiation pain in a shoulder or shoulder-blade
 - E. sickliness the back vault of vagina
876. Ulcerous diaeases behaves to the diseases

- A. innate
 - B. because of alcoholism
 - C. because of the broken circulation of blood
 - D. * chronic recurrent
 - E. traumatic
877. What nosotropic conditionality Vosresenky's sign at acute pancreatitis:
- A. * Inflammatory edema of pancreas
 - B. Reflex paresis of colon
 - C. Thrombosis of abdominal aorta
 - D. Embolism of abdominal aorta
 - E. Development of peritonitis
878. What colouring of chair is most characteristic for bleeding from the ulcer of stomach and duodenum?
- A. * Tarry excrement
 - B. Presence on the formed excrement of strokes of red blood
 - C. Littlechanged blood in an excrement
 - D. Excrement of the raspberry colouring with the admixtures of mucus
 - E. Acholic excrement
879. What complication the ulcerous illness of stomach is most characteristically for the patients of elderly and senile age
- A. perforation
 - B. perforation + bleeding
 - C. pylorus stenosis
 - D. malignization + penetration
 - E. * bleeding
880. What external signs are characteristic for the profuse bleeding from a gastric ulcer?
- A. Vomiting by the littlechanged blood, excrement of the raspberry colouring
 - B. * Vomiting by the littlechanged blood, tarry darkly-cherry chair
 - C. Vomiting by a complete mouth by dark blood with clots, black formed excrement
 - D. Vomiting on the type of "coffee-grounds", presence on the formed incandescence of strokes of red blood
 - E. Tarry darkly-cherry chair
881. What from operations does not execute at surgical treatment complicated acute pancreatitis:
- A. Through draining the stuffing-box bag
 - B. Abdominisation the pancreas
 - C. Omentopankreatopeksiy
 - D. Left-side resection of gland
 - E. * Pancreatojejunostomy
882. What from preparations has the expressed bacteriostatic action on Helicobacter pyloris
- A. * trichopol
 - B. Liciviroton
 - C. oxiferiskorbon
 - D. atropine
 - E. pirinzsipin
883. What from the transferred diseases can be reason of the pseudoperitoneal syndrome?
- A. dissecting aneurysm of the abdominal part of aorta.
 - B. Extraperitoneal haematoma.

- C. Nephrolithiasis, nephrocolic
 - D. Thrombosis the pelvis veins
 - E. * All transferred
884. What from the transferred operations does not belong to organ protective
- A. trunk vagotomy
 - B. * resection by Bilrot II
 - C. selective vagotomy
 - D. selective proximal vagotomy
 - E. the all transferred does not belong
885. What from the transferred operations on the stomach organ protective is
- A. * selective proximal vagotomy
 - B. resection by Bilrot I
 - C. resection by Bilrot II
 - D. gastrectomy
 - E. all are transferred
886. What hormones undertake the protective operating on the mucous membrane of stomach, except for
- A. * ACTH
 - B. epidermal factor of growth
 - C. prostaglandin E
 - D. estrogens
 - E. STH
887. What is necrectomy:
- A. Delete the necrotic area within the limits of nonviable fabrics
 - B. * Delete the necrotic area within the limits of healthy fabrics
 - C. Delete part of organ with his transversal cutting within the limits of the changed fabrics
 - D. Total delete of organ
 - E. There is not a faithful answer
888. What is pancreatectomy:
- A. Delete the necrotic area within the limits of nonviable fabrics
 - B. Delete the necrotic area within the limits of healthy fabrics
 - C. Delete part of organ with his transversal cutting within the limits of the changed fabrics
 - D. * Total delete of organ
 - E. There is not a faithful answer
889. What is resection the pancreas:
- A. Delete the necrotic area within the limits of nonviable fabrics
 - B. Delete the necrotic area within the limits of healthy fabrics
 - C. * Delete part of organ with his transversal cutting within the limits of the changed fabrics
 - D. Total delete of organ
 - E. There is not a faithful answer
890. What is sequestrotomy:
- A. * Delete the necrotic area within the limits of nonviable fabrics
 - B. Delete the necrotic area within the limits of healthy fabrics

- C. Delete part of organ with his transversal cutting within the limits of the changed fabrics
 - D. Total delete of organ
 - E. There is not a faithful answer
891. What kind of operation is more rationally to perform for the patient with the cancer of caecum, complicated by acute intestinal obstruction in early terms of the disease:
- A. * Right-side hemicolectomy with ileotransversoanastomosis
 - B. Formation of ileostomy
 - C. Formation of caecostomy
 - D. Hartmann's operation
 - E. Mikulich's operation
892. What localization of ulcer is most characteristic for the patients of elderly and senile age
- A. * cardial department of stomach
 - B. overhead third of gullet
 - C. lower third of gullet
 - D. bulb of duodewnum
 - E. small curvature
893. What method diagnostics hte ulcerous illness most informing
- A. * esophagogastroduodenoscopy
 - B. analysis of excrement on the hidden blood
 - C. X-ray
 - D. global analysis of blood
 - E. research of gastric secretion
894. What most effective blocker secretion of pancreas at acute pancreatitis:
- A. Cyanocobalamin
 - B. Ubretid
 - C. Arginine
 - D. * Sandostatin
 - E. Benzogeksoniy
895. What most effective treatment the unformed complicated cyst is:
- A. Conservative treatment
 - B. * External draining cyst
 - C. Resection cyst within the limits of the unchanged gland
 - D. Cysticenterostomy
 - E. Cystogastrostomy
896. What most effective treatment the unformed uncomplicated cyst is:
- A. * Conservative treatment
 - B. External draining cyst
 - C. Resection cyst within the limits of the unchanged gland
 - D. Cysticenterostomy
 - E. Cystogastrostomy
897. What must be done in the case of development the posoperative peritonitis?
- A. to appoint antibiotics
 - B. to appoint anaesthetic
 - C. to execute laparocenthezis
 - D. to execute lasparoscopy
 - E. * to execute laparotomy

898. What operation is most often used for localization the formed pseudocyst in the area of tail the pancreas:
- A. Cystojejunostomy on the eliminated loop
 - B. External draining the cyst
 - C. Cystogastrostomy
 - D. * Cystoduodenostomy
 - E. Cystoenteroanastomosis
899. What operation is used for suppuration the pseudocysts of pancreas:
- A. Cystojejunostomy on the eliminated loop
 - B. * External draining the cyst
 - C. Cystogastrostomy
 - D. Cystoduodenostomy
 - E. Cystoenteroanastomosis
900. What operation is used for the pseudocyst of pancreas in the 3th stage of its forming:
- A. * Cystojejunostomy on the eliminated loop
 - B. External draining the cyst
 - C. Cystogastrostomy
 - D. Cystoduodenostomy
 - E. Cystoenteroanastomosis
901. What preparation does behave to blocker H2-retseptors?
- A. * tavegil
 - B. obzidan
 - C. hystdol
 - D. cerucal
 - E. oraza
902. What preparation does behave to blocker of muscarine receptors of coating cages?
- A. cymetidin
 - B. eglonin
 - C. * gastocepini
 - D. etimsiloli
 - E. vinylin
903. What preparation is applied at violation the extrasecretory function of pancreas at a chronic pancreatitis:
- A. Pyracetam
 - B. Papaverin
 - C. Pantocrin
 - D. * Panzinorm
 - E. Panthenol
904. What preparations from the cytostatic group use for intensifying the chronic pancreatitis:
- A. Cyanocobalamin
 - B. Methyluracil
 - C. * 5-fluorouracil
 - D. Furadolizon
 - E. Mezimforte
905. What preparations, except for other properties, own yet and a bacteriostatic effect on Helicobacter pyloris

- A. * all are transferred preparations
 - B. Almagel
 - C. Vinylin
 - D. De-nol
 - E. Claritromycin
906. What products are recommended in the diet of № 1?
- A. * hen in a steam kind
 - B. pancakes
 - C. raw egg-white
 - D. bread rye fresh
 - E. acute cheeses
907. What surgical pathology is a characteristic symptom of toxic «scissors» ?
- A. appendicitis
 - B. cholecystitis
 - C. pancreatitis
 - D. * peritonitis
 - E. mesadenitis
908. What symptom is most characteristic in the initial phase of peritonitis:
- A. sickliness and overhanding of pelvic peritoneum at rectal research.
 - B. dulling in declivous places at percussion of stomach
 - C. * tension of muscles the front abdominal wall.
 - D. swelling of stomach
 - E. melena
909. What syndrome is characteristic for hemorrhagic erosive gastritis?
- A. * ulcerous
 - B. hemorrhagic;
 - C. pain;
 - D. all answers are correct;
 - E. all answers are not correct.
910. What time urgent operations are executed at acute bleeding
- A. * 6 – 12 hours;
 - B. 6 – 10 hours;
 - C. 6 – 8 hours
 - D. 6 – 14 hours;
 - E. 6 – 20 hours
911. What type of peritonitis are fibrinogenous impositions at on a parietal and visceral peritoneum?
- A. at serosal.
 - B. at festering.
 - C. at fibrinogenous
 - D. at putrid.
 - E. * at all
912. What violation of mineral exchange is characteristic for patients with ulcerous illness of stomach and intestine
- A. hypocalcemia
 - B. * hypokaliemia
 - C. Hyponatremia

- D. Hypercalcemia
 - E. hyperkalemia
913. When apply Teylor's method at ulcerous illness
- A. * at conservative treatment perforated ulcers
 - B. at conservative treatment sanguifluous ulcers
 - C. at conservative treatment penetration ulcers
 - D. at conservative treatment malignization ulcers
 - E. at conservative treatment of cicatrical pyloristhenosis
914. Widespread festering peritonitis is investigation of all above-stated diseases, except for:
- A. perforative ulcers of duodenum
 - B. phlegmonous cholecystitis
 - C. * hydrocholecystitis
 - D. destructive pancreatitis
 - E. volvulus of sigmoid bowel
915. With what disease above all things is it necessary to differentiate the acute peritonitis?
- A. bronchitis
 - B. enterorrhagia
 - C. anaemia
 - D. * acute vascular purpura
 - E. endotoxemia
916. The "light intervals" is characteristic for such phase of acute intestinal obstruction:
- A. Ileus scream"
 - B. Intoxications
 - C. Terminal
 - D. Initial manifestations
 - E. False improvement
917. A typical sign for invagination in irrigoscopy is:
- A. Cockades"
 - B. Candles"
 - C. Rat tail"
 - D. Spizharny's sign
 - E. Bartomier-Mikhelson's sign
918. Acute intestinal obstruction according to the level of obstruction is divided on:
- A. * Small intestinal, large intestinal
 - B. Small intestinal, large intestinal, caecal
 - C. High, low, middle
 - D. Long, short
 - E. High, small intestinal, large intestinal
919. Acute intestinal obstruction according to the origin is divided on:
- A. * Dynamic and mechanical
 - B. Dynamic and paralytic
 - C. Dynamic, spastic and strangulation
 - D. Strangulation and spastic
 - E. Mechanical and paralytic
920. Appearance „splashing sound" in acute intestinal obstruction is caused:
- A. * By the accumulation of liquid and gases in the afferent loop of intestine

- B. By the accumulation of liquid and gases in the efferent loop of intestine
 - C. By the presence of liquid in the abdominal cavity
 - D. By the presence of free gas in the abdominal cavity
 - E. By the presence of free gas and liquid in the abdominal cavity
921. Arterial mesenteric acute intestinal obstruction belongs to:
- A. * obturation
 - B. Strangulation
 - C. Paralytic
 - D. spastic
 - E. Mixed
922. Bloody discharge during enema in acute intestinal obstruction is the sign of:
- A. * Hemodynamic intestinal obstruction as the result of mesenteric thrombosis
 - B. Obturation intestinal obstruction
 - C. Strangulation intestinal obstruction
 - D. Adhesive intestinal obstruction
 - E. Hemorrhoids
923. Choose the correct algorithm of operative intervention for the III stage of acute intestinal obstruction:
- A. * Laparotomy, liquidation of the source of peritonitis, intestinal intubation, sanation of abdominal cavity, suturing of the abdomen or laparostomy
 - B. Laparotomy, liquidation of obstruction, intestinal intubation, sanation of abdominal cavity, suturing of the abdomen
 - C. Laparotomy, liquidation of obstruction, intestinal intubation, sanation of abdominal cavity, laparostomy
 - D. Laparotomy, liquidation of obstruction, intestinal intubation, sanation of abdominal cavity, suturing of the abdomen
 - E. Laparotomy, liquidation of obstruction, liquidation of peritonitis, sanation of abdominal cavity, suturing of the abdomen
924. Choose the correct algorithm of the operative intervention for the II stage of acute intestinal obstruction :
- A. * Laparotomy, liquidation of obstruction, intestinal intubation, sanation of abdominal cavity, suturing of the abdomen
 - B. Laparotomy, liquidation of the source of peritonitis, sanation of abdominal cavity, suturing of the abdomen
 - C. Laparotomy, liquidation of obstruction, sanation of abdominal cavity, suturing of the abdomen
 - D. Laparotomy, liquidation of obstruction, intestinal intubation, sanation of abdominal cavity, laparostomy
 - E. Laparotomy, liquidation of obstruction, liquidation of the source of peritonitis, intestinal intubation, sanation of abdominal cavity, suturing of the abdomen
925. Choose the operation, which is not performed in intestinal obstruction, caused by cancer of sigmoid intestine:
- A. * Collateral ileotransversoanastomosis
 - B. Obstructive resection (Hartmann's operation)
 - C. Colostomy
 - D. Resection of sigmoid intestine with anastomosis "end to end"
 - E. Resection of sigmoid intestine with closed anastomosis and temporal transversostomy

926. Choose the type of acute intestinal obstruction which is characterized by excretion of blood from anus:
- A. * Invagination of iliac intestine in caecum
 - B. Paralytic
 - C. Spastic
 - D. Volvulus of small intestine
 - E. Intestinal infarction
927. Conservative treatment of intestinal obstruction is indicated in all cases, except for:
- A. * Torsion
 - B. Spastic obstruction
 - C. Paralytic obstruction
 - D. Coprostasis
 - E. There is no right answer
928. Dehydration of the organism in acute intestinal obstruction most rapidly develops in:
- A. * Torsion of small intestine
 - B. Torsion of sigmoid intestine
 - C. Tumours of rectum with the phenomena of obstruction
 - D. Obturation large intestinal obstruction
 - E. Ileocaecal invagination
929. Describe the Kloiber's cups in large intestinal obstruction:
- A. * Not wide, high, single
 - B. Wide, not high, multiple
 - C. Not characteristic
 - D. Wide, not high, with folds
 - E. Of different size, localization
930. Describe the Kloiber's cups in small intestinal obstruction:
- A. * Wide, not high, multiple
 - B. Not wide, high, single
 - C. Not characteristic
 - D. Wide, not high, with folds
 - E. Of different size, localization
931. Disorders, resulting in spastic acute intestinal obstruction:
- A. * All mentioned
 - B. Hysteria
 - C. Lead colics
 - D. Neuroses
 - E. None of mentioned
932. During the examination of patient with acute intestinal obstruction: the Zege-Maitenphel's and "Obuhov's hospital" symptoms are positive. What type of obstruction it is characteristic for?
- A. * Sigmoid intestine torsion
 - B. Ileocaecal invagination
 - C. Obturation by the tumour of ascending intestine
 - D. Torsion of small intestine
 - E. All mentioned is correct
933. During the revision of the site of obstruction an afferent loop looks like:
- A. * Dilated and overfull intestinal content

- B. Spastic
 - C. Collapsed
 - D. The same as efferent loop
 - E. The diagnostics is not a necessary
934. Dynamic intestinal obstruction is divided on:
- A. * Spastic, paralytic
 - B. Strangulation, obturation, mixed
 - C. Strangulation, spastic, paralytic
 - D. Mechanical, spastic, paralytic
 - E. Mechanical and paralytic
935. For acute intestinal obstruction the followings types of operations are possible, except for:
- A. * Gastrostomy
 - B. Right-side hemicolectomy
 - C. Resections of intestine
 - D. Colostomy
 - E. Hartmann's operation
936. For intestinal obstruction caused by invagination is characteristic:
- A. * Bloody discharges from rectum
 - B. The wave-like abdominal pain
 - C. Tumorous formation in a right iliac area by palpation
 - D. Bolus-like feces
 - E. Atony of rectal sphincter
937. For paralytic intestinal obstruction is characteristic:
- A. * Delay of stool and gases and acute distension of abdomen
 - B. Asymmetry of abdomen
 - C. The expressed wave-like pain in the abdominal cavity
 - D. Zege-Maitenphel's sign
 - E. Effusion in the abdominal cavity
938. For performance of siphon enema in acute intestinal obstruction it is necessary to prepare:
- A. * 10 – 15 litres and more of warm water
 - B. 500 ml. of cold water
 - C. 1 litre of mineral water with gas
 - D. 5 litres of mineral water without gas
 - E. 500 ml. of warm water
939. For stimulation of peristalsis of intestine used:
- A. * Proserin
 - B. No-spa
 - C. Analgin
 - D. Droperidol
 - E. Dimedrol
940. For strangulation is not typical:
- A. * Normal body temperature
 - B. Tension of abdominal wall
 - C. Leucocytosis
 - D. Frequent vomit
 - E. Wahl's symptom

941. For strangulation is not typical:
- * Leucopenia
 - Tension of abdominal wall
 - Frequent vomit
 - Body temperature 37,5°C and higher
 - Wahl's symptom
942. For the differential diagnostic of acute intestinal obstruction with perforative gastric ulcer it is necessary to perform above all:
- * Plain X-ray of abdominal cavity
 - Pneumogastrography
 - Roentgenoscopy of the abdomen
 - Gastroscopy
 - Laparoscopy
943. For the high small intestinal obstruction is not characteristic:
- * Zege-Maitenphel's sign
 - The wave-like abdominal pain
 - Splashing sound" (Sklyarov's sign)
 - Multiple vomiting
 - Cloyber's cups on X-ray
944. For the initial stage of acute strangulation intestinal obstruction the most frequent first symptom is:
- * Primary reflex vomiting and pain shock
 - Appearance of outpouching of intestinal loops on abdominal wall (visible peristalsis)
 - Strengthening of peristalsis
 - Delay of stool and gases
 - Lost of peristalsis
945. For the low large intestinal obstruction all is characteristic, except for:
- * Rapid dehydration
 - Delay of stool
 - Appearances of Cloyber's cups
 - Gradual progression of symptoms
 - Abdominal distension
946. For the patient of 72 years old, who entered in late term with acute intestinal obstruction caused by the tumour of sigmoid intestine, the most acceptable tactic is the following:
- * Preparation to the operation for 2-3 hours with following Hartmann's operation
 - Inspection and performance of operation in 48-72 hours
 - Only conservative therapy
 - Infusion therapy and repeated siphon enemas
 - Urgent operation with resection of the intestine and anastomosis „end to end”
947. For the torsion of small intestine is not characteristic:
- * Zege-Maitenphel's sign
 - Asymmetry of abdomen
 - Splashing sound”
 - Multiple vomiting
 - The wave-like abdominal pain
948. For the treatment measures in obturation intestinal obstruction all mentioned belong, except:
- * Prescribing of medicines which increase intestinal peristalsis

- B. Prescribing of spasmolytics
 - C. Performing of siphon enema
 - D. Introducing of nasogastral tube for intestinal decompression
 - E. Corrections of water-electrolytes disturbances
949. For what type of acute intestinal obstruction is possible the "syndrome of minor signs"?
- A. * Obturation
 - B. Spastic
 - C. Strangulation
 - D. Invagination
 - E. All types
950. For which type of intestinal obstruction is characteristic the absence of Sklyarov's, Wahl's, Kywul's signs?
- A. * Spastic
 - B. Strangulation
 - C. Obturation
 - D. Invagination
 - E. None of mentioned
951. If the disease begins from a sudden „knife” pain, it is characteristically for:
- A. * Perforative gastric ulcer
 - B. Spastic acute intestinal obstruction
 - C. Volvulus
 - D. Peritonitis
 - E. Acute pancreatitis
952. If the high level of normal hematocrit is 40 %, what level of fluid must be infused on every 5 % increase in acute intestinal obstruction?
- A. * 1000 ml. of liquid
 - B. 200 ml. of liquid
 - C. 2500 ml. of liquid
 - D. 100 ml. of liquid
 - E. Transfusion of liquid is not indicated
953. In acute intestinal obstruction the basic X-ray sign is:
- A. * Air-fluid levels, Kloiber's cups
 - B. Expressed limitation of mobility of the right dome of diaphragm
 - C. Diffusely dilated loops of bowels
 - D. Free gas in the abdomen
 - E. Sklyarov's sign
954. In case of large intestine obstruction, the surgeon must begin the intraoperative revision:
- A. * From cecum to the rectosigmoid part of colon
 - B. From cecum to the level of obstruction
 - C. From the level of obstruction to the rectosigmoid part of colon
 - D. A revision is not necessary
 - E. A revision is not performed
955. In case of small intestine obstruction, the surgeon must begin the intraoperative revision:
- A. * From Treitz ligament to ileocecal angle
 - B. From Treitz ligament to the level of obstruction
 - C. From the level of obstruction to ileocecal angle
 - D. A revision is not necessary

- E. A revision is not performed
956. In early period of acute small intestinal obstruction in the organism of patient observed all, except:
- A. * Decrease of hematocrit
 - B. Dehydration
 - C. Increase of hematocrit
 - D. Decrease of blood potassium
 - E. There is no correct answer
957. In paralytic intestinal obstruction the stimulation of peristalsis of intestine is performed:
- A. * Only after infusion therapy and correction of hypovolemia
 - B. Depending on age
 - C. Contra-indicated
 - D. Depending on a clinical situation
 - E. Not indicated
958. In patient 75 years old two days ago aroused up the volvulus of sigmoid intestine. On operation was found out its necrosis, acute distension of the colon. What is the optimal variant of the operation?
- A. * Resection of sigmoid intestine with formation of colostomy
 - B. Resection of sigmoid intestine with anastomosis „end to end”
 - C. Resection of sigmoid intestine with anastomosis "side to side"
 - D. Sigmoidostomy
 - E. All answers are incorrect
959. In patient of 42 years old after the considerable physical exertion appeared spastic pain in the whole abdomen, nausea, double vomiting, distension of abdomen, retention of gases. What disease such clinical picture is characteristic for?
- A. * Acute intestinal obstruction
 - B. Perforative gastric ulcer
 - C. Acute pancreatitis
 - D. Acute appendicitis
 - E. Acute gangrenous cholecystitis
960. In patient of 82 years old with acute intestinal obstruction caused by the tumour of sigmoid intestine, who entered in late terms, the most rational tactic of treatment is the following:
- A. * Preparing for the operation during 2-3 hours with following performance of Hartmann's operation
 - B. Examination and performance of operation in 48-72 hours
 - C. Only conservative therapy
 - D. Infusion therapy and repeated siphon enemas
 - E. Urgent operation with performance of sigmoid intestine resection and anastomosis "end to end"
961. In patient was diagnosed acute intestinal obstruction caused by cancer of caecum. During an urgent operation was revealed, that regional lymph nodes are not enlarged, the distant metastases of the tumour are absent. What is the tactic?
- A. * Right-side hemicolectomy
 - B. Caecostomy
 - C. Resection of caecum and ascending intestine
 - D. Hartmann's operation
 - E. Ileostomy

962. In the initial stages of obturation colon obstruction the most valuable is the following medical tactic:
- A. * First conservative treatment and if it is failed – immediate operation
 - B. Urgent operation, that allows to prevent necrosis of intestine and its perforation
 - C. Performance of operation in 48-72 hours after inspection and establishment of the cause of intestinal obstruction
 - D. Direct performance of operation with formation of colostomy or enterostomy
 - E. Direct performance of Hartmann's operation
963. In what case the drainage of the abdominal cavity is inadvisable in operative treatment of acute intestinal obstruction?
- A. * None of mentioned cases
 - B. In formation of anastomosis
 - C. In formation of haematoma
 - D. In formation of stoma
 - E. In all these cases
964. In what type of intestinal obstruction one of the symptom is the red water after a cleaning enema:
- A. * Intestinal infarction
 - B. Paralytic
 - C. Spastic
 - D. Torsion of small intestine
 - E. Invagination
965. In what type of intestinal obstruction one of the symptom will be a blood discharge from rectum:
- A. * Invagination
 - B. Paralytic
 - C. Spastic
 - D. Torsion of small intestine
 - E. Intestinal infarction
966. Increased and loud peristaltic noises in early period of the disease are characteristic for:
- A. * mechanical intestinal obstruction
 - B. paralytic intestinal obstruction
 - C. Perforative gastric ulcer
 - D. Gangrenous cholecystitis
 - E. Thrombosis of mesenteric vessels
967. Invagination much more frequent in:
- A. * Children
 - B. Pregnant
 - C. Elderly people
 - D. Teenagers
 - E. Does not depend on age
968. Is a fecal vomit is characteristic sign for acute intestinal obstruction?
- A. * Yes, in III phase
 - B. Yes, in I phase
 - C. Never
 - D. Always
 - E. In obturation acute intestinal obstruction

969. Is it reasonable to perform a paranephral blockade in acute intestinal obstruction?
- A. * Yes
 - B. No
 - C. Yes, except strangulation
 - D. Yes, except obturation
 - E. Contraindicated
970. Is obligatory the consultation of anesthesiologist at suspicion on acute intestinal obstruction:
- A. * Yes
 - B. No
 - C. Only anaesthesist
 - D. Only internist
 - E. Only one of them
971. Is obligatory the digital examination of rectum at suspicion on acute intestinal obstruction?
- A. * Yes
 - B. No, if you know that acute intestinal obstruction is of obturative origin
 - C. Yes, if you know that acute intestinal obstruction is of obturative origin
 - D. No
 - E. Yes, except for children, pregnant
972. Is obligatory the X-ray examination at suspicion on acute intestinal obstruction?
- A. * Yes
 - B. No, if you know that acute intestinal obstruction is of obturative origin
 - C. Yes, if you know that acute intestinal obstruction is of obturative origin
 - D. No
 - E. Yes, except for children and pregnant
973. Is the intestinal obstruction suitable in the treatment of ²⁻²² stage of acute intestinal obstruction?
- A. * Yes
 - B. No
 - C. Only in the case of formation of anastomosis
 - D. Only in strangulation acute intestinal obstruction
 - E. Only in obturation acute intestinal obstruction
974. Is the programmable laparostomy suitable in the treatment of ²⁻²² stage of acute intestinal obstruction?
- A. * No
 - B. Yes
 - C. Only in the case of formation of anastomosis
 - D. Only in strangulation acute intestinal obstruction
 - E. Only in obturation acute intestinal obstruction
975. Large intestine obstruction is more frequently caused:
- A. * By the malignant tumours of intestine
 - B. Foreign bodies
 - C. By the adhesions of abdominal cavity
 - D. By gall-stones
 - E. Helminths
976. Mechanical intestinal obstruction is divided on:
- A. * Strangulation, obturation, mixed
 - B. Mechanical, spastic, paralytic

- C. Strangulation, spastic, paralytic
 - D. Spastic, paralytic
 - E. Mechanical and paralytic
977. Mechanism of the development of intestinal obstruction, caused by gall-stones:
- A. * Stones produce bile acids which irritate the bowel causing its spasm
 - B. Stones mechanically irritate the wall of the bowel and causing its spasm
 - C. Stones secrete toxic substances which irritate the wall of the bowel causing its spasm
 - D. Stones obturate the lumen of the bowel
 - E. All answers are correct
978. Name a radical operation in the volvulus of sigmoid colon:
- A. * A resection of sigmoid colon in any modifications
 - B. Mesosygmoplication
 - C. Gartman's operation
 - D. Mesosygmopexia
 - E. Detorsion of volvulus
979. Name a tactical error during performance of operation for intestinal obstruction:
- A. * Refuse of intestine intubation
 - B. Resection of necrotic part of bowel
 - C. Lavage of abdominal cavity
 - D. Draining of abdominal cavity
 - E. Liquidation of obstruction
980. Name duration of conservative treatment of acute intestinal obstruction in the stage of compensation?
- A. * 5-7 days
 - B. 1-2 days
 - C. 12-24 hours
 - D. To 12 hours
 - E. not less than 2 weeks
981. Name the causes of intestinal obstruction:
- A. * All mentioned causes
 - B. Long mesentery of small or large intestine which results in the mobility of their loops
 - C. Tumours of the abdominal cavity and retroperitoneal space
 - D. None of mentioned
 - E. Adhesions of abdominal cavity
982. Name the character of peristalsis in the onset of the acute intestinal obstruction:
- A. * Hyperperistalsis
 - B. Normal peristalsis
 - C. Absent
 - D. Variable
 - E. Heard only in regions upper the obstruction
983. Name the leading signs of acute intestinal obstruction:
- A. * Wave-like pain, vomiting, delay of gases and stool
 - B. Knife-like" pain, wooden abdomen, proper anamnesis
 - C. Knife-like" pain, wooden abdomen, vomiting
 - D. Wave-like pain, anaemia
 - E. Nausea, loss of appetite, metallic taste in the mouth

984. Name the method of examination which is not obligatory in acute intestinal obstruction:
- A. * All are obligatory
 - B. General blood analysis
 - C. General urine analysis
 - D. Coagulogramm
 - E. Electrolytes
985. Name the methods of intestinal intubation:
- A. * All types are acceptable, depending on a clinical situation
 - B. Through gastrostoma
 - C. Through ceco- or appendicostoma
 - D. Through the rectum
 - E. Nasogasral
986. Name the methods of operative treatment of acute intestinal obstruction for preventing of its relapse:
- A. * Operations of Noble and Child-Pott
 - B. Gartman's operation
 - C. Anisevich operation
 - D. Kirsh operation
 - E. Zeremin-cummel operation
987. Name the most frequent causes of obturation intestinal obstruction:
- A. * All mentioned
 - B. Scar and inflammatory stricture
 - C. Foreign bodies
 - D. Helminths
 - E. Tumours
988. Name the most frequent form of colon volvulus:
- A. * Volvulus of sygmoid colon
 - B. Volvulus of cecum
 - C. Volvulus of ascending colon
 - D. Volvulus of appendix
 - E. Volvulus of descending colon
989. Name the most important method of investigation in the diagnostic of „acute intestinal obstruction“:
- A. * Research of barium passage trough intestine
 - B. Plain X-ray of abdominal cavity
 - C. Fibrogastroduodenoscopy
 - D. Laparoscopy
 - E. Biochemical blood analysis
990. Name the most severe form of strangulation intestinal obstruction:
- A. * Nodulus
 - B. Volvulus
 - C. Adhesive intestinal obstruction
 - D. Invagination
 - E. None of the mentioned forms
991. Name the operation of choice in intestinal obstruction caused by solid colon tumour of hepatic angle (T3N0M0):

- A. * Right-side hemicolectomy with formation of ileotransversoanastomosis and obligatory intestinal intubation
 - B. Right-side hemicolectomy without intestinal intubation
 - C. Collateral anastomosis without the removal of tumour
 - D. A resection of hepatic angle of colon with ascendotransversoanastomosis
 - E. Formation of ileostomy in the right iliac region
992. Necrosis of intestine is possible in all variants of intestinal obstruction, except for:
- A. * Obturation of small intestine by gall-stone
 - B. Torsion of small intestine
 - C. Nodulus
 - D. Hernia strangulation
 - E. Acute mesenteric obstruction
993. Optimal access in the operative treatment of acute intestinal obstruction is:
- A. * Middle laparotomy
 - B. Phaneuil's
 - C. Vinkelman's
 - D. Fedorov's
 - E. Right pararectal
994. Select the phases of the clinical course of acute intestinal obstruction:
- A. „Iliac scream”, intoxication, terminal
 - B. Initial, to development
 - C. Initial, intoxications, „iliac scream”
 - D. „Iliac scream”, purulent, septic complications
 - E. Acute onset, false improvement, peritonitis
995. Stool and gases in volvulus of small intestine:
- A. * Is possible in case of high localization of obstruction
 - B. Is possible after digital examination of rectum
 - C. Impossible
 - D. Is possible in case of low localization of obstruction
 - E. Is possible after washing out of the stomach
996. Tactic of treatment of acute sigmoid torsion without the visual changes of intestine consists of:
- A. * Detorsion of sigmoid intestine with mesosigmoplication
 - B. Colostomy
 - C. Resection with primary anastomosis
 - D. Hartmann's operation
 - E. Liquidation of torsion
997. The "trident", "crescent" signs are characteristic for such type of acute intestinal obstruction, as:
- A. * Invagination
 - B. Spastic
 - C. Obturation
 - D. Strangulation
 - E. All kinds
998. The absolute indication for operative treatment of acute intestinal obstruction°:
- A. * III phase of the course of acute intestinal obstruction
 - B. II phase of the course of acute intestinal obstruction

- C. I phase of the course of acute intestinal obstruction
 - D. The prolonged anamnesis of acute intestinal obstruction
 - E. Dynamic acute intestinal obstruction
999. The acute obstruction of duodeno-jejunal junction is characterized by:
- A. * Vomiting by bile
 - B. The phenomena of paralytic intestinal obstruction
 - C. Diffuse distension of abdomen
 - D. Delay of stool and gases
 - E. Tenesmi
1000. The air-fluid levels (Kloiber's cups) are not characteristic for such type of acute intestinal obstruction, as:
- A. * Spastic
 - B. Paralytic
 - C. Obturation
 - D. Invagination
 - E. All kinds
1001. The cause of obturation intestinal obstruction includes all, except:
- A. * Torsion of intestinal mesentery
 - B. Inflammatory adhesions
 - C. Gall-stones
 - D. Invagination
 - E. Compression by tumour
1002. The contributory factor of the development of obturation is:
- A. * Stool stones
 - B. Long intestinal mesentery
 - C. Adhesions in abdominal cavity
 - D. All of mentioned
 - E. None of mentioned
1003. The contributory factor of the development of strangulation is:
- A. * Long intestinal mesentery
 - B. Stool stones
 - C. Gall-stones
 - D. Tumour
 - E. None of mentioned
1004. The criteria of the efficiency of gastrointestinal tract passage renewal during conservative therapy of acute intestinal obstruction is:
- A. * Pulling of gases and stool
 - B. Normalization of rectal temperature
 - C. Absence of Shchotkin-Blumberg's sign
 - D. Feeling of heartburn
 - E. None of mentioned
1005. The criterion of the conservative therapy efficiency of acute intestinal obstruction is:
- A. * Absence of Sklyarov's sign
 - B. Absence of Shchotkin-Blumberg's sign
 - C. Absence of Sitkovsky's sign
 - D. Normalization of rectal temperature
 - E. None of mentioned

1006. The decompression of gastrointestinal tract includes everything, except:
- A. * Lavage of abdominal cavity
 - B. Endoscopic intubation
 - C. Enterotomy with aspiration
 - D. Washing of the stomach
 - E. Performing of siphon enema
1007. The development of paralytic intestinal obstruction is caused by all mentioned except for:
- A. * Lead poisoning
 - B. Peritonitis
 - C. Acute pancreatitis
 - D. Retroperitoneal hematoma
 - E. Disorders of mesenteric circulation of blood
1008. The diagnosis of acute intestinal obstruction is established on the basis of:
- A. * Character of pain and roentgenologic signs
 - B. Anamnesis and laboratory information
 - C. Anamnesis, clinical research and laboratory information
 - D. Clinical course of the disease
 - E. Only by roentgenologic signs
1009. The diagnostic measures which immediately performed in suspicion on acute intestinal obstruction include everything, except:
- A. * Angiography of abdominal cavity
 - B. Auscultation of abdomen
 - C. Plain X-ray of abdominal cavity
 - D. Introducing of nasogastric tube for the decompression of intestine
 - E. Palpation of abdomen, digital examination of rectum
1010. The dividing of mechanical intestinal obstruction is based on:
- A. * Compression of mesenteric vessels
 - B. Compression of bowel loops
 - C. Involvement in a tumour process
 - D. Degree of adhesions
 - E. Medical tactic
1011. The efficiency of conservative measures for acute intestinal obstruction are determined by clinical changes except:
- A. * Decrease of height of Menber's cups on X-ray
 - B. Appearance of stool and gases
 - C. Diminishing of distension of the abdomen
 - D. Loss of peristalsis
 - E. Diminishing of pain intensity
1012. The first phase of the clinical course of acute intestinal obstruction lasts:
- A. * To 12 hours
 - B. To 2 hours
 - C. To 1 day
 - D. More than 1 day
 - E. To 1 hour
1013. The Grekov's sign in acute intestinal obstruction is:
- A. * Gaping of anus

- B. Good heard cardiac tones during auscultation of the abdomen
 - C. Dullness in the lower regions
 - D. Sound of falling drop
 - E. Noise of splash
1014. The I phase of the clinical course of acute intestinal obstruction is:
- A. Ileus scream"
 - B. Intoxications
 - C. Terminal
 - D. Initial manifestations
 - E. False improvement
1015. The II phase of the clinical course of acute intestinal obstruction is:
- A. * Intoxications
 - B. Terminal
 - C. Ileus scream"
 - D. Initial manifestations
 - E. False improvement
1016. The III phase of the clinical course of acute intestinal obstruction is:
- A. * Terminal
 - B. Intoxications
 - C. Ileus scream"
 - D. Initial manifestations
 - E. False improvement
1017. The indication for cecopexia in the operative treatment of invagination is:
- A. * For the prophylaxis of relapses
 - B. For self desinvagination
 - C. For better desinvagination
 - D. Is not indicated
 - E. Not performed
1018. The indication for operative treatment of acute intestinal obstruction is:
- A. * Mechanical acute intestinal obstruction in inefficient conservative treatment
 - B. I phase of the course of acute intestinal obstruction
 - C. II phase of the course of acute intestinal obstruction
 - D. The prolonged anamnesis of acute intestinal obstruction
 - E. Mechanical acute intestinal obstruction
1019. The Kloiber's cups on X-ray examination are:
- A. * A presence of gas and levels of fluid in the loops of bowel
 - B. Presence of gallstones in the loops of bowel
 - C. A presence of foreign bodies in the loops of bowel
 - D. A presence of intestinal content in the loops of bowel
 - E. A presence of stool stones in the loops of bowel
1020. The leading signs in acute intestinal obstruction are:
- A. * Wave-like pain, ðâîðà, delay of gases and stool
 - B. Knife-like" pain, wooden abdomen, proper anamnesis
 - C. Knife-like" pain, wooden abdomen, vomiting
 - D. Wave-like pain, anaemia
 - E. Nausea, loss of appetite, metallic taste in the mouth

1021. The Loteyssen's sign in acute intestinal obstruction is:
- A. * Good heard cardiac tones during auscultation of the abdomen
 - B. Noise of splash
 - C. Dullness in the lower regions
 - D. Sound of falling drop
 - E. Gaping of anus
1022. The manifestation of the Anshuts sign in large intestinal obstruction is:
- A. * Considerable meteorism in the right iliac region
 - B. Visible peristalsis of intestine
 - C. Sound of intestinal splash”
 - D. Sound of falling drop”
 - E. A metallic sound over the dilated bowel
1023. The manifestation of the Babuk's sign is:
- A. * A presence of blood after the repeated siphon enema
 - B. Periodic appearance of wave-like pain in the abdomen
 - C. Tenesmi during palpation of elastic tumour in the abdomen
 - D. Bleeding from the rectum
 - E. The presence of the fluid level in abdominal cavity
1024. The manifestation of the Cruvelew's sign is:
- A. * Bleeding from the rectum
 - B. Tenesmi during palpation of elastic tumour in the abdomen
 - C. A presence of the blood after the repeated siphon enema
 - D. Periodic appearance of wave-like pain in the abdomen
 - E. A presence of solitary level in abdominal cavity
1025. The manifestation of the Kywul's sign in acute intestinal obstruction is:
- A. * A metallic sound over the dilated bowel
 - B. Noise of intestinal splash
 - C. Sound of falling drop”
 - D. Gaping of anus
 - E. Sounds of the beginning, quiet of the end”
1026. The manifestation of the Rush's sign is:
- A. * Tenesmi during palpation of elastic tumour in the abdomen
 - B. Periodic appearance of wave-like pain in the abdomen
 - C. A presence of the blood after the repeated siphon enema
 - D. Bleeding from the rectum
 - E. A presence of solitary level in abdominal cavity
1027. The manifestation of the Shlange's sign in acute intestinal obstruction is:
- A. * Peristalsis of the bowel which arises up after palpation of the abdomen
 - B. Sounds of the beginning, quiet of the end”
 - C. Sound of falling drop”
 - D. Noise of intestinal splash
 - E. Gaping of anus
1028. The manifestation of the Simagin's sign is:
- A. * A presence of solitary level in abdominal cavity
 - B. Tenesmi during palpation of elastic tumour in the abdomen
 - C. A presence of the blood after the repeated siphon enema
 - D. Bleeding from the rectum

- E. Periodic appearance of wave-like pain in the abdomen
1029. The manifestation of the Tiliyax's sign is:
- A. * Periodic appearance of wave-like pain in the abdomen
 - B. Tenesmi during palpation of elastic tumour in the abdomen
 - C. A presence of blood after the repeated siphon enema
 - D. Bleeding from the rectum
 - E. A presence of solitary level in abdominal cavity
1030. The manifestation of the Wahl's sign in acute intestinal obstruction is:
- A. * Limited elastic formation in the abdomen
 - B. A metallic sound over the dilated bowel
 - C. Sound of falling drop”
 - D. Gaping of anus
 - E. Noise of intestinal splash
1031. The method of choice in sigmoid intestine torsion can be such operations, except:
- A. * Nobble's operation
 - B. Resection of sigmoid intestine with anastomosis "end to end"
 - C. Hartmann's operation
 - D. Mesosigmoplication after Gagen-Thorn
 - E. All answers are correct
1032. The most characteristic manifestation of the tumour obturation of colon is:
- A. * Chronic intestinal obstruction
 - B. Acute intestinal obstruction
 - C. Dynamic intestinal obstruction
 - D. Paralytic intestinal obstruction
 - E. Wooden abdomen
1033. The most frequent cause of small intestine mechanical obstruction is:
- A. * Adhesions of abdominal cavity
 - B. Gall-stones
 - C. Foreign bodies
 - D. Tumours
 - E. Helminths
1034. The most frequent cause of the large intestinal obstruction is:
- A. * Tumours
 - B. Invagination
 - C. Volvulus
 - D. Hemorrhoids of IV degree
 - E. Errors in the diet
1035. The most frequent cause of the mechanical intestinal obstruction is:
- A. * Adhesions
 - B. Tumours of small intestine
 - C. Internal hernia
 - D. Invagination
 - E. Dull trauma of abdomen
1036. The most frequently the sygmoid volvulus arises in:
- A. * Elderly patients with frequent constipations
 - B. Females with menstrual arrest

- C. Children
 - D. Elderly patients people with permanent diarrhea
 - E. New-borns
1037. The nodulus involves in the process:
- A. * Not less than two parts of intestine
 - B. One part of intestine
 - C. One or more parts of intestine
 - D. All parts of intestine
 - E. Parietal peritoneum
1038. The nodulus requires:
- A. * Untie the knot, if impossible – resection of the bowel
 - B. Resection of the bowel
 - C. Untie the knot
 - D. To perform the stoma. The second stage the resection of the bowel
 - E. None of mentioned
1039. The percussion in acute intestinal obstruction reveals:
- A. * Tympanic sound
 - B. No changes
 - C. Dull sound
 - D. Tympanic sound in the region of liver
 - E. Dullness in lower sites
1040. The peritonitis, caused by perforation of duodenal ulcer is characterised by such type of obstruction:
- A. * Paralytic
 - B. Spastic
 - C. Strangulation
 - D. There is no characteristic type
 - E. The obstruction can not develop in this case
1041. The peritonitis, caused by perforation of gastric ulcer is characterised by such type of obstruction:
- A. * Paralytic
 - B. Spastic
 - C. Strangulation
 - D. There is no characteristic type
 - E. The obstruction can not develop in this case
1042. The positive Gregersen's reaction is the most typical for such form of intestinal obstruction:
- A. * obturation of tumour origin
 - B. spastic
 - C. strangulation
 - D. adhesive
 - E. characteristic for all mentioned
1043. The purpose of conservative therapy in compensated acute intestinal obstruction:
- A. * All mentioned
 - B. Preoperative preparation
 - C. Treating
 - D. Detoxication
 - E. Diagnostic

1044. The purpose of conservative therapy in decompensated acute intestinal obstruction:
- A. * Preoperative preparation
 - B. Treating
 - C. Detoxication
 - D. All mentioned
 - E. None of mentioned
1045. The raspberry jelly-like feces are characteristic for:
- A. * Invagination
 - B. Stenosis of pilorus
 - C. Meckel's diverticulum
 - D. Chronic appendicitis
 - E. Chronic enterocolitis
1046. The Samarina's sign does not include:
- A. * Excess sodium in the blood plasma
 - B. Erythrocytosis
 - C. Leucocytosis
 - D. Hypoproteinemia
 - E. Drop in the chloride content of the blood serum
1047. The Samarina's sign does not include:
- A. * Hyperproteinemia
 - B. Leucocytosis
 - C. Erythrocytosis
 - D. Decreased potassium in the blood plasma
 - E. Hypovitaminosis
1048. The sign of what disease is the expressed abdominal pain, which does not relieve after intake of spasmolytics and analgetics?
- A. * Acute disturbance of mesenteric bloodflow
 - B. Chronic enterocolitis
 - C. Acute appendicitis
 - D. Acute cholecystitis
 - E. Chronic pancreatitis
1049. The similar signs of the clinical manifestation of acute intestinal obstruction and perforation ulcer are:
- A. * Acute course with sudden intensive pain and muscular tension of the abdomen
 - B. The abdominal pain with irradiation in the right shoulder-blade and shoulder
 - C. Slowly-progressive course with gradual increasing pain
 - D. Presence of diarrhea
 - E. Absence of general signs
1050. The similar signs of the clinical manifestation of acute pancreatitis and acute intestinal obstruction are:
- A. * Presence of the signs of intoxication and repeated vomiting
 - B. Presence of diarrhea
 - C. Positive Mayo-Robson sign
 - D. A high level of urine diastase
 - E. Presence of constipation
1051. The Sklyarov's sign in acute intestinal obstruction is:

- A. * Noise of splash
 - B. Good heard cardiac tones during auscultation of the abdomen
 - C. Dullness in the lower regions
 - D. Sound of falling drop
 - E. Gaping of anus
1052. The Spasokukotsky's sign in acute intestinal obstruction is:
- A. * Sound of falling drop
 - B. Good heard cardiac tones during auscultation of the abdomen
 - C. Dullness in the lower regions
 - D. Noise of splash
 - E. Gaping of anus
1053. The treatment of patients with strangulation acute intestinal obstruction which accompanied by the manifestations of peritonitis must include:
- A. * 2 hours of conservative treatment, then operative
 - B. To 12 hours conservative treatment, then operative
 - C. Immediately operative without conservative
 - D. Conservative in ambulatory conditions
 - E. During the first days conservative with the gradual increase of volume infusion
1054. The tumour obturation of cecum requires:
- A. * Right-side hemicolectomy
 - B. Resection of cecum
 - C. Cecostomy
 - D. Only ileostomy
 - E. Only intubation of small intestine
1055. To detect the presence of "sequestral fluid" in the lumen of the bowel in mechanical intestinal obstruction is possible by means of:
- A. * Ultrasound examination
 - B. X-ray examination
 - C. Irrigography
 - D. Fibrocolonoscopy
 - E. Digital examination of rectum
1056. To determine the viability of strangulated intestine it is necessary to be oriented on the followings signs, except:
- A. * Presence of strangulation groove
 - B. Color of intestine
 - C. Presence of peristalsis
 - D. The pulsation of mesenteric vessels
 - E. All answers are incorrect
1057. To differentiate acute pancreatitis with acute intestinal obstruction used such methods of examination, except:
- A. * General analysis of blood
 - B. Determination of amylase in blood
 - C. Determination of diastase in urine
 - D. Plain X-ray of abdominal cavity
 - E. All answers are correct
1058. To the criteria of permanent renewal of the gastrointestinal tract passage as efficiency of conservative treatment belongs:

- A. * Absence of stagnant content in the stomach
 - B. Absence of Shchotkin-Blumberg's sign
 - C. Normalization of rectal temperature
 - D. Feeling of heartburn
 - E. None of mentioned
1059. To the method of early diagnostics of acute intestinal obstruction belongs:
- A. * Plain X-ray of abdominal cavity
 - B. Laparoscopy
 - C. Ultrasound examination of abdominal cavity
 - D. Irrigography
 - E. Colonoscopy
1060. Treatment of patients with acute intestinal obstruction in the stage of decompensation must be:
- A. * 2-4 hours of conservative, then operative
 - B. To 24 hours of conservative, then operative
 - C. Immediately operative
 - D. During the first days conservative treatment with the gradual increase of volume of infusion
 - E. Conservative in ambulatory conditions
1061. What among mentioned is correct in relation to the diagnostics of acute intestinal obstruction:
- A. * All answers are correct
 - B. The typical roentgenologic signs appear in 3-6 hours from the onset of mechanical intestinal obstruction
 - C. In strangulation obstruction the X-ray with barium is contra-indicated
 - D. More higher the obstruction, more quick the vomiting arise up
 - E. In operated on the abdominal organs patients the cause of the obstruction is represented by adhesions, and in not operated – by tumours of intestine
1062. What among the mentioned types of intestinal obstruction has primary vascular origin:
- A. * Mesenteric obstruction
 - B. Arteriomesenteric obstruction
 - C. Adhesive
 - D. Strangulation
 - E. Obturation
1063. What are the causes of the dynamic intestinal obstruction:
- A. * All answers are correct
 - B. Leaden colic
 - C. Uremia
 - D. Pancreonecrosis
 - E. Peritonitis
1064. What are the Kloiber's cups?
- A. * Horizontal air-fluid levels
 - B. Gas bubble of the stomach
 - C. Folds of intestine
 - D. Gas sickles under the domes of diaphragm
 - E. None of mentioned

1065. What are the measures of resection of nonviable region of bowel in thrombosis of mesenteric vessels?
- A. * 30-40 sm. of afferent and 15-20 sm. of efferent part
 - B. 10-15 sm. of afferent and efferent part
 - C. Within the limits of visible healthy tissues
 - D. 30 sm. of afferent and efferent part
 - E. 20 sm. afferent and efferent part
1066. What belongs to the clinical signs of invagination intestinal obstruction?
- A. * All mentioned signs
 - B. The periodic abdominal pain
 - C. A presence of elastic, slightly painful, mobile formation in abdominal cavity
 - D. Appearance of blood in a stool
 - E. None of mentioned signs
1067. What can be the cause of mechanical intestinal obstruction?
- A. * All mentioned
 - B. Strangulated hernia
 - C. Scar strictures
 - D. Adhesions, tumours
 - E. Drainage mistakes
1068. What changes in laboratory indexes are characteristic for adhesive intestinal obstruction?
- A. * Hypoproteinemia
 - B. Lymphocytosis
 - C. Excess sodium in the blood plasma
 - D. Increased diastase
 - E. No changes
1069. What changes in laboratory indexes are characteristic for nodulus?
- A. * Hyponatremia
 - B. Lymphocytosis
 - C. Leucopenia
 - D. Increased diastase
 - E. No changes
1070. What changes in laboratory indexes are characteristic for spastic intestinal obstruction?
- A. * No changes
 - B. Leucopenia
 - C. Lymphocytosis
 - D. Excess sodium in the blood plasma
 - E. Increased diastase
1071. What complication mainly influences on the choice of operation:
- A. * Perforation and peritonitis
 - B. Bleeding
 - C. Obstruction of intestine
 - D. Distant metastases
 - E. Ulceration
1072. What does acute intestinal obstruction, caused by a tumour obturation, require?
- A. * Operative intervention
 - B. Liquidations of the tumour by chemotherapy
 - C. Liquidations of the tumour by radiotherapy

- D. Surgery only after chemotherapy
 - E. Only symptomatic treatment
1073. What does not belong to conservative therapy of acute intestinal obstruction?
- A. * Liquidation of hypervolemia
 - B. Decompression of gastrointestinal tract
 - C. The struggle against abdominal-pain shock
 - D. Detoxication
 - E. Correction of microcirculation
1074. What does not belong to conservative therapy of acute intestinal obstruction?
- A. * Liquidation of hypervolemia
 - B. Decompression of gastrointestinal tract
 - C. A struggle against abdominal-pain shock
 - D. Detoxication
 - E. Correction of microcirculation
1075. What does not belong to the fight against abdominal-pain shock?
- A. * Performing of siphon enema
 - B. Paranephral novocaine blockade
 - C. Neuroleptanalgesia
 - D. Peridural anaesthesia
 - E. Spasmolytic therapy
1076. What does the appearance of the signs of peritoneal irritation and the thrombosis of mesenteric vessels mean?
- A. * Necrosis of all layers of the bowel wall
 - B. Necrosis of muscular layer of this segment of bowel
 - C. About necrosis of serous membrane of this segment of bowel
 - D. Necrosis of mucus membrane of this segment of bowel
 - E. About paresis of intestine
1077. What does the decompression of gastro-intestinal tract include?
- A. * Stomach wash out, introduction of nasogastral zond, and performing of cleaning enemas
 - B. Only washing out of the stomach
 - C. Only introduction of nasogastral zond
 - D. Only performing of cleaning enemas
 - E. Introduction of rectal mirror
1078. What does the positive Mondor's sign in acute intestinal obstruction mean?
- A. Sounds of the beginning, quiet of the end”
 - B. Noise of intestinal splash
 - C. Frequent uncontrollable vomiting
 - D. Limited elastic formation in the abdomen
 - E. Gaping of anus
1079. What does volvulus mean?
- A. * Torsion of the bowel with its mesentery along longitudinal axis
 - B. Torsion of the bowel with the mesentery of another loop
 - C. Invagination of one part of the bowel in another
 - D. Obturation of the bowel lumen
 - E. Torsion of the bowel with its mesentery along transverse axis

1080. What is not characteristic for acute high intestinal obstruction:
- A. * Distension of abdomen in the first hours of the disease
 - B. Rapid decrease of the volume of circulating blood
 - C. Frequent prolonged vomiting
 - D. Rapid dehydration
 - E. Wave-like pain
1081. What is not typical for the high small intestinal obstruction:
- A. * Early even distension of abdomen
 - B. A presence of Cloyber's cups in the upper half of abdomen
 - C. Early vomiting
 - D. Wave-like pains
 - E. Rapid worsening of the patient condition
1082. What is the aim of conservative therapy in compensated acute intestinal obstruction?
- A. * Treating
 - B. Preoperative preparation
 - C. Detoxication
 - D. All mentioned
 - E. None of mentioned
1083. What is the aim of conservative therapy in decompensated acute intestinal obstruction?
- A. * Preoperative preparation
 - B. Treating
 - C. Detoxication
 - D. All mentioned
 - E. None of mentioned
1084. What is the aim of the operative treatment of volvulus if the bowel „alive“?
- A. * Detorsion, decompression, fixing to the abdominal wall
 - B. Detorsion, resection, fixing to the abdominal wall
 - C. Detorsion, dilation, decompression, fixing to the abdominal wall
 - D. Detorsion, dilation, decompression
 - E. Decompression, fixing to the abdominal wall
1085. What is the character of peristalsis at the beginning of acute intestinal obstruction:
- A. * Hyperperistalsis
 - B. Normal peristalsis
 - C. Absent
 - D. Variable
 - E. Heard only in the region higher to obstruction
1086. What is the definition of intestinal obstruction?
- A. * Complete or partial disturbance of passage through intestinal tract
 - B. Syndrome of acute vomiting
 - C. Constipation
 - D. Absence of stool
 - E. Disturbances of defecation
1087. What is the drawback of Gartman's operation?
- A. * Formation of stoma
 - B. Volvulus of mesentery
 - C. Development of early adhesive intestinal obstruction
 - D. A long term of patient stay in the hospital

- E. Death of patient
1088. What is the essence of arterial mesenteric intestinal obstruction?
- A. * superior mesenteric artery compresses the duodenum
 - B. duodenum compresses the superior mesenteric artery
 - C. acute intestinal obstruction on the background of mesenteric thrombosis
 - D. mesenteric thrombosis caused by obstruction
 - E. duodenum compresses inferior mesenteric artery
1089. What is the forced patient's position with embolism of mesenteric vessels?
- A. * Knee-elbow or on-side position with flexed legs
 - B. On abdomen
 - C. Semi-sitting position
 - D. On back with flexed legs
 - E. Lotus position
1090. What is the Gartman's operation in cancer of the left side of colon or rectum with obturative intestinal obstruction?
- A. * A resection of the cancered segment of bowel with suturing of distal end and formation of the stoma of proximal end of the bowel
 - B. A resection of the cancered segment with formation of primary anastomosis
 - C. Anterior resection of rectum
 - D. Formation of stoma
 - E. Formation of transversostoma
1091. What is the mechanism of gall-stones entrance in the lumen of small intestine which results in acute intestinal obstruction:
- A. * As a result of the bed sore in the walls of gallbladder and bowel which adjoins to him
 - B. From bile ducts through the Vater's papilla
 - C. Creates in the lumen of small intestine by itself
 - D. All variants are correct
 - E. None of variants is correct
1092. What is the most frequent localization of invagination:
- A. * the region of cecum
 - B. splenic angle
 - C. hepatic angle
 - D. Rectosigmoid angle
 - E. Patients with the Led's syndrome
1093. What is the volvulus?
- A. * Torsion of the bowel with its mesentery along longitudinal axis
 - B. Torsion of the bowel with the mesentery of another loop
 - C. Invagination of one part of the bowel in another
 - D. Obturation of the bowel lumen
 - E. Torsion of the bowel with its mesentery along transverse axis
1094. What kind of acute intestinal obstruction the invagination belongs to?
- A. * Mixed
 - B. Paralytic
 - C. Volvulus
 - D. Strangulation
 - E. Dynamic

1095. What kind of acute intestinal obstruction the nodule belongs to?
- A. * Strangulation
 - B. Paralytic
 - C. Volvulus
 - D. Dynamic
 - E. Mixed
1096. What kind of operation is more rationally to perform for the patient with the cancer of caecum, complicated by acute intestinal obstruction in early terms of the disease:
- A. * Right-side hemicolectomy with ileotransversoanastomosis
 - B. Formation of ileostomy
 - C. Formation of caecostomy
 - D. Hartmann's operation
 - E. Mikulich's operation
1097. What of mentioned is considered to be the morphological signs of dynamic intestinal obstruction?
- A. * All mentioned signs
 - B. Slight thickening of intestinal wall
 - C. Edema of intestinal tissues
 - D. A presence of fluid and gases in the lumen of the bowel
 - E. None of mentioned
1098. What organ diseases results in the embolism of mesenteric vessels?
- A. * Heart
 - B. Blood
 - C. Stomach
 - D. Liver
 - E. Lungs
1099. What pathology the Gray-Turner's sign is characteristic for?
- A. * Acute pancreatitis
 - B. Perforative gastric ulcer
 - C. Spastic acute intestinal obstruction
 - D. Volvulus
 - E. Peritonitis
1100. What pathology the Mayo-Robson's sign is characteristic for?
- A. * Acute pancreatitis
 - B. Perforative gastric ulcer
 - C. Spastic acute intestinal obstruction
 - D. Volvulus
 - E. Peritonitis
1101. What pathology the phrenicus sign is characteristic for?
- A. * Perforative gastric ulcer
 - B. Spastic acute intestinal obstruction
 - C. Volvulus
 - D. Peritonitis
 - E. Acute pancreatitis
1102. What pathology the Rovsing's sign is characteristic for?
- A. * Appendicitis

- B. Spastic acute intestinal obstruction
 - C. Perforative gastric ulcer
 - D. Volvulus
 - E. Acute cholecystitis
1103. What pathology the Spizharny's sign is characteristic for?
- A. * Perforative gastric ulcer
 - B. Spastic acute intestinal obstruction
 - C. Volvulus
 - D. Peritonitis
 - E. Acute pancreatitis
1104. What precedes the development of intestinal obstruction of gall-stones origin?
- A. * Attack of biliary colic and clinic of acute cholecystitis
 - B. Constipation
 - C. Diarrhea
 - D. Clinics of acute pancreatitis
 - E. Nausea and vomiting
1105. What signs are typical for intestinal obstruction?
- A. * Wahl's, Kywul's, Sklyarov's, Grekov's, Spasokukotsky's
 - B. Jobber's, Spizharny's, Rattner's
 - C. Grekov's, Murphy's, Georgievsky's, Mussi
 - D. Rovsing's, Sitkovsky's, Rozdolsky's, Bartomier-Mikhelson's, Obrastsow's, Shchotkin-Blumberg
 - E. Mozart's, Beethoven's
1106. What treatment is indicated in gall-stones intestinal obturation?
- A. * Only operative
 - B. Only conservative
 - C. Operative in the case of the development of peritonitis
 - D. Treatment is not required
 - E. Tactic depends on the size of stone
1107. What treatment tactic of acute intestinal obstruction, caused by a tumour obturation is required?
- A. * Operative intervention
 - B. Liquidation of tumour by a chemotherapy
 - C. Liquidations of tumour by radiotherapy
 - D. Operative intervention only after chemotherapy
 - E. Only symptomatic treatment
1108. What type of vomit is characteristic for acute intestinal obstruction?
- A. * Frequent, without relief
 - B. Single, with relief
 - C. With relief
 - D. Not characteristically
 - E. Double
1109. When is the intubation zond removed from intestine after the operation for acute intestinal obstruction?
- A. * On the next day after appearance of peristalsis, but not later than on 7th day
 - B. On the 5th day
 - C. On the 4th day

- D. On the 3th day
 - E. On desire of the patient
1110. When is the operative intervention for acute intestinal obstruction accompanied by the drainage of abdominal cavity?
- A. * In all mentioned cases
 - B. In formation of stoma
 - C. In increased bleeding during dissecting of adhesions
 - D. In formation of anastomosis
 - E. None of mentioned cases
1111. Where the pain irradiates in acute intestinal obstruction?
- A. * The irradiation is not characteristic
 - B. In lumbar region
 - C. In the right shoulder
 - D. In shoulder-blade
 - E. In testicle
1112. Which form of intestinal obstruction belongs the retrograde incarceration of small intestine:
- A. * Strangulation
 - B. Richter's hernia
 - C. Litre's hernia
 - D. Paralytic
 - E. Obturative
1113. Which of the phase of acute intestinal obstruction the „Gippokrath face” is characteristic for?
- A. * III
 - B. I
 - C. II
 - D. Not characteristic
 - E. In all
1114. Which type of acute intestinal obstruction is connected with previous operations:
- A. * Strangulation
 - B. Spastic
 - C. Obturation
 - D. Invagination
 - E. All kinds
1115. Which type of strangulation intestinal obstruction is characterised by the Rush's, Babuck's signs:
- A. * Invagination
 - B. Nodulus
 - C. Adhesive intestinal obstruction
 - D. Obturation by gall-stones
 - E. Obturation by tumour
1116. A patient 40 years old, suffered ulcerous diseases of stomach. Last 2 days the pain became less intensive, but weakness and dizziness were appeared. Rose from a bed and lost consciousness. Pale. There are insignificant pains in epigastrium. It is
- A. Combination perforation with bleeding
 - B. Perforation
 - C. Malignization of ulcer

- D. Stenosis of ulcer
 - E. * Gastroenteric bleeding
1117. A peristalsis is absent as a rule in:
- A. * peritonitis
 - B. paraproctitis
 - C. appendicitis
 - D. colitis
 - E. cholecystitis
1118. A peritoneal cavity is closed in:
- A. * males
 - B. females
 - C. children
 - D. persons of elderly age
 - E. young persons
1119. A peritoneal cavity is opened in:
- A. * females
 - B. males
 - C. children
 - D. persons of elderly age
 - E. young persons
1120. A peritoneum consists of sheets:
- A. * visceral, parietal
 - B. parietal
 - C. visceral
 - D. visceral, extraorganic
 - E. parietal, extraorganic
1121. A presence of peritonitis is the indication for the operation:
- A. * absolute
 - B. relative
 - C. conditional
 - D. no operation required
 - E. planned
1122. A programmed laparostomy is indicated in peritoneal endotoxiosis of:
- A. * IIIA or IV degree
 - B. II degree
 - C. IIIA-B degree
 - D. I stage
 - E. V stage
1123. Abdominal, infracostal, retropleural accesses are used for the drainage of the abscess:
- A. * anterior subphrenic
 - B. back subhepatic
 - C. anterior subhepatic
 - D. interintestinal
 - E. back subphrenic
1124. Abscess is the form of peritonitis:
- A. * focal

- B. diffuse
- C. total
- D. general
- E. unfocal

1125. Absence of diaphragm excursion in breathing is characteristic for the abscess:
- A. * subphrenic
 - B. pelvic
 - C. appendicular
 - D. Douglas space
 - E. iliac
1126. Absolute indication to operative treatment the ulcerous illness is
- A. heavy pain syndrome
 - B. * perforation of ulcer
 - C. relapses more than 2 one time per a year
 - D. ulcerous anamnesis more than 10 years
 - E. giant ulcers
1127. Absolute indication to operative treatment the ulcerous illness is
- A. * voluminous bleeding
 - B. callous ulcers
 - C. relapses more than 2 one time per a year
 - D. ulcerous anamnesis more than 10 years
 - E. heavy pain syndrome
1128. Absolute indication to operative treatment the ulcerous illness is
- A. ulcerous anamnesis more than 10 years
 - B. * bleeding what do not stopped with conservative
 - C. perforation ulcer in anamnesis
 - D. heavy pain syndrome
 - E. relapses more than 3 times per a year
1129. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. ulcerous anamnesis more than 10 years
 - C. relapse ulcer after the resection of stomach
 - D. relapses more than 3 times per a year
 - E. * cicatricial-ulcerous stenosis of pylorus
1130. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. * malignization ulcers
 - C. ulcerous anamnesis more than 10 years
 - D. heavy pain syndrome, proof heartburn
 - E. relapse ulcer after vagotomy
1131. Absolute sign of unstable hemostasis
- A. * profluvium blood from a vessel;
 - B. absence blood in a stomach and bulb of duodenum;
 - C. presence light blood and faltungs of blood in a stomach;
 - D. all answers are correct;
 - E. all answers are not correct

1132. According to microbial character the peritonitis is distinguished:
- A. * aerobic, anaerobic, mixed
 - B. aerobic, clostridial, mixed
 - C. anaerobic, nonclostridial, mixed
 - D. bacteroid, streptococcal, mixed
 - E. aerobic, staphylococcal, mixed
1133. According to the course the peritonitis is distinguished:
- A. * acute, chronic, subacute
 - B. fulminant, acute, chronic
 - C. acute, torpid, subacute
 - D. acute, subacute, fulminant
 - E. acute, progressive, subacute
1134. According to the severity the peritonitis is distinguished:
- A. * slight, moderate, severe, grave, terminal
 - B. slight, moderate, severe, terminal
 - C. slight, moderate, severe
 - D. slight, moderate, severe, terminal, agonal
 - E. slight, moderate, severe, agonal
1135. According to the spread the peritonitis is distinguished:
- A. * local, diffuse, general
 - B. furunculus, diffuse, general
 - C. furunculus, diffuse, total
 - D. local, furunculus, general
 - E. local, diffuse, furunculus
1136. After the operation for peritonitis performed:
- A. * intestinal intubation
 - B. fixing of the intestine
 - C. stimulation of the intestine
 - D. dilation of the intestine
 - E. removal of the intestine
1137. After what operation at ulcerous illness the natural arcade of meal is saved on a digestive tract
- A. Valter-Braun's gastroenterostomy
 - B. not saved after any operation
 - C. resection by Bilrot II
 - D. * resection by Bil'rot I
 - E. saved after all transferred operations
1138. After what operation innervation of pyloric department of stomach is saved
- A. * selective vagotomy
 - B. barrel vagotomy
 - C. selective proximal vagotomy
 - D. at all transferred
 - E. not saved after all operations
1139. Ambulatory treatment after the operation for diffuse peritonitis lasts:
- A. * 1,5-4 months
 - B. 2-3 weeks
 - C. 1-2 months

- D. 10-15 days
 - E. 6 months
1140. Among causes of death rate from acute surgical diseases peritonitis possesses the place:
- A. * first
 - B. second
 - C. third
 - D. fourth
 - E. fifth
1141. Appearance of pain during percussion of anterior abdominal wall in peritonitis is the sign:
- A. * Rozdolsky's
 - B. Spasokukotsky's
 - C. Shchotkin-Blumberg
 - D. Kulenkampf's
 - E. Voskresensky's
1142. Appearance of pain during sliding of fingers on anterior abdominal wall in peritonitis is the sign:
- A. * Voskresensky's
 - B. Sitkovsky's
 - C. Rovsing's
 - D. Rozdolsky's
 - E. Ortner's
1143. At beginning bleeding from an ulcer
- A. * pain diminishes
 - B. pain increases
 - C. there is knife-like pain
 - D. character of pain does not change
 - E. girdle pain
1144. At bleeding emergency operative interferences are executed
- A. * to 3 hours
 - B. to 1,5 hour
 - C. to 6 hours
 - D. to 8 hours
 - E. 6 – 12 hours
1145. At III stage blood loss at the bleeding ulcer the patient loses
- A. over 1000 ml blood
 - B. * over 2000 ml blood
 - C. over 500 ml blood
 - D. over 2500 ml blood
 - E. over 1500 ml blood
1146. At III stage blood loss at the bleeding ulcer the patient loses
- A. more than 25 % blood volume
 - B. * more than 30 % blood volume
 - C. more than 20 % blood volume
 - D. more than 15 % blood volume
 - E. more than 35 % blood volume
1147. At the duodenum ulceroperation of choice is

- A. * resection by Bilrot I
 - B. resection by Bilrot II
 - C. resection of duodenum
 - D. selective proximal vagotomy
 - E. sewing up of ulcer
1148. At the gastroenteric bleeding the middle degree of blood loss is diagnosed at next indexes
- A. Hb below 80 g/l
 - B. * Hb 80-100 g/l
 - C. red corpuscles below $2,5 \cdot 10^{12}/l$
 - D. red corpuscles of $3,5-4,0 \cdot 10^{12}/l$
 - E. Ht below 25%
1149. At the III item of activity hemostasis and III stage blood loss from the I – III stage blood loss indicated
- A. * urgent operations (6 – 12 hours);
 - B. emergency operations (to 3 hours);
 - C. exigent operations (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
1150. At the V item activity of hemostasis and at the recurrent bleeding of the I – III item of blood loss indicated
- A. * emergency operations (to 3 hours);
 - B. urgent operations (6 – 12 hours);
 - C. exigent (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
1151. At ulcerous illness can a bleeding source be
- A. artery;
 - B. veins;
 - C. shallow vessels and ulcers;
 - D. all answers are not correct.
 - E. * all answers are correct
1152. Basic role in pathogenesis of peritonitis belongs:
- A. * to cytokines
 - B. to lymphocytes
 - C. to enzymes
 - D. to monocytes
 - E. to leucocytes
1153. Bergman's sign is characteristic for
- A. * bleeding ulcer
 - B. for cicatricial-ulcerous pylorostenosis
 - C. perforated ulcers
 - D. penetration ulcers
 - E. malignization ulcers
1154. Berhstein's sign characteristic for
- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers

- D. malignized ulcers
 - E. for cicatrical-ulcerous pylorostenosis
1155. Bleeding ulcer, complicated blood loss III stage degrees, requires
- A. * blood and its components transfusions
 - B. transfusion of salt solutions
 - C. transfusion of colloid solutions
 - D. transfusion of salt and colloid solutions
 - E. infusion therapy does not need
1156. Blood loos I stage characterized such indexes
- A. Ht 48-44, Hb 120
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 31-23, Hb 80
 - D. * Ht 38-32, Hb 100
 - E. Ht 44-40, Hb 110 /?
1157. Blood loos II stage characterized
- A. * Ht 23 and below, Hb 50 and below
 - B. Ht 31-23, Hb 80
 - C. Ht 44-40, Hb 110
 - D. Ht 48-44, Hb 120
 - E. Ht 48-44, Hb 120
1158. Blood loos III stage characterized a degree such indexes
- A. * Ht 31-23, Hb 80
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 38-32, Hb 100
 - D. Ht 44-40, Hb 110
 - E. Ht 48-44, Hb 120
1159. Cryptogenic peritonitis - is:
- A. * primary
 - B. subacute
 - C. acute
 - D. secondary
 - E. chronic
1160. De-Cerven's sing is characteristic for
- A. bleeding ulcer
 - B. * perforated ulcers
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatrical-ulcerous pylorostenosis
1161. Deep palpation in peritonitis is impossible in the stage:
- A. * first
 - B. second
 - C. third
 - D. fourth
 - E. fifth
1162. Diet at bleeding gastric and duodenum ulcers
- A. * Meulengracht's

- B. 1 by Pevznerom
 - C. 5 by Pevznerom
 - D. 15 by Pevznerom
 - E. 7 by Pevznerom
1163. Disappearance or diminishing the pain with beginning of bleeding from an ulcer is
- A. * Bergman's sign
 - B. Spazarskiy's sign
 - C. Mendel's sign
 - D. De Keven's sign
 - E. Eleker's sign
1164. Distinguished such operative accesses for subphrenic abscesses:
- A. * peritoneal, retroperitoneal
 - B. retroperitoneal
 - C. peritoneal
 - D. pleural
 - E. pleural, retropleural
1165. Duration the period of primary shock at a perforated ulcer
- A. * 3-6 hours
 - B. 6-12 hours
 - C. 1-3 hours
 - D. 12-24 hours
 - E. 24-36 hours
1166. During one day the inflamed peritoneum can absorb a volume of fluid to:
- A. * 70 litres
 - B. 20 litres
 - C. 40 litres
 - D. 50 litres
 - E. 10 litres
1167. Eleker's sign is characteristic for
- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorostenosis
1168. Esophagogastroduodenoscopy can find out next changes in a stomach, except for
- A. tumours
 - B. ulcers
 - C. bleeding polypuses
 - D. erosions
 - E. * changes of evacuation function
1169. For bleeding ulcer characteristic sign is
- A. * pain in an epigastrium;
 - B. knife-like pain;
 - C. signs irritation of peritoneum;
 - D. presence fresh blood in incandescence
 - E. melena;

1170. For bleeding ulcer characteristically
- * melena
 - tension the muscles of front abdominal wall
 - Spazarskiy's sign
 - sickliness the back vault of vagina
 - irradiation pain in a shoulder or shoulder-blade
1171. For motion of disease ulcerous illness of middle weight characteristically
- development of complications
 - * relapses 1-2 times per a year
 - 4 and anymore relapses on a year
 - 5 and more relapses are on a year
 - 3 and anymore relapses on a year
1172. For perforated ulcer characteristically
- * tension the muscles of front abdominal wall
 - melena
 - vomiting by coffee-grounds
 - high intestinal impassability
 - vomiting stagnant gastric maintenance
1173. For pneumoperitoneum is characteristic symptom
- * Zhober's;
 - Khelatid's;
 - Podlag's;
 - Vigats's;
 - Udin's.
1174. For subphrenic abscess is characteristic the X-ray sign:
- * displacement of the diaphragm upward
 - thinning of the diaphragm
 - thickening of the diaphragm
 - displacement of the diaphragm downward
 - displacement of the diaphragm is absent
1175. For the abscess of Douglas space used surgical access:
- * rectal
 - subpubic
 - perineal
 - suprapubic
 - obturatorial
1176. For the heavy flow of ulcerous illness characteristically
- 2 and anymore relapses on a year
 - * 3 and anymore relapses on a year
 - 4 and anymore relapses on a year
 - 5 and more relapses are on a year
 - 6 and more relapses are on a year
1177. For the heavy flow of ulcerous illness characteristically
- * development of complications
 - seasonal exacerbation more not frequent 1-2 times per a year
 - 1-2 relapse on a year
 - liquid, but protracted exacerbation

- E. exacerbation duration more than 10 days
1178. For the parietal peritoneum of anterior and back abdominal wall is characteristic:
- A. * exudation
 - B. imbibition
 - C. salivation
 - D. proliferation
 - E. resorbtion
1179. For the parietal peritoneum of diaphragm is characteristic:
- A. * resorbtion
 - B. imbibition
 - C. proliferation
 - D. exudation
 - E. salivation
1180. For the parietal peritoneum of lateral wall of the abdomen is characteristic:
- A. * resorbtion
 - B. imbibition
 - C. salivation
 - D. exudation
 - E. proliferation
1181. For the terminal stage of peritonitis is characteristic:
- A. * face of Gippokrath
 - B. cyanosys of the abdomen
 - C. frog belly
 - D. Caput Medusae"
 - E. tension of the abdomen
1182. Forced diuresis belongs to:
- A. * intracorporal methods of detoxication
 - B. extracorporal methods of detoxication
 - C. programmed laparostomy
 - D. peritoneal lavage
 - E. peritoneal dialysis
1183. Frequent painful urination is characteristic for such abscess:
- A. * pelvic
 - B. paraappendicular
 - C. iliac
 - D. appendicular
 - E. retroperitoneal
1184. From what department degestyive tract developmentp more frequent than all the bleeding at the Mallory-Weiss syndrome
- A. gastric fundus
 - B. * cardial pert;
 - C. pyloric department;
 - D. from duodenal;
 - E. from a thick intestine
1185. Giant ulcer is an ulcer measuring
- A. over 4,5 cm

- B. * over 3 cm
 - C. over 4 cm
 - D. over 5 cm
 - E. over 3,5 cm
1186. Hemobilia is
- A. * all answers are correct;
 - B. bleeding the bilious ways and liver;
 - C. bleeding the general bilious channel;
 - D. bloody clot in the big duodenal papilla;
 - E. all answers are not correct.
1187. How many anatomic regions are involved in inflammatory process in local peritonitis?
- A. * one
 - B. 2 – 3
 - C. 3 – 6
 - D. 6 – 9
 - E. all regions
1188. How many layers does the peritoneum of mesentery of large intestine consist of?
- A. * 4
 - B. 3
 - C. 5
 - D. 6
 - E. 7
1189. How many layers does the peritoneum of mesentery of small intestine consist of?
- A. * 7
 - B. 4
 - C. 5
 - D. 6
 - E. 3
1190. How many sites of the drainage of abdominal cavity used in peritonitis?
- A. * four
 - B. two
 - C. three
 - D. one
 - E. five
1191. How to prevent the development of peritonitis in the penetrate wound of the abdomen on the prehospital stage?
- A. * to impose an aseptic bandage and inject antibiotics
 - B. to impose an aseptic bandage and inject cardiac medicines
 - C. to anesthetize the wound by novocaine. aseptic bandage
 - D. to inject antibiotics
 - E. to put a cold on the abdomen
1192. If the inflammatory process in peritonitis spreads on 2-3 anatomic regions it is named:
- A. * diffuse
 - B. local
 - C. total
 - D. general
 - E. widespread

1193. Impaired fibrinolysis is the base of pathogenesis of peritonitis:
- A. * focal
 - B. unfocal
 - C. total
 - D. general
 - E. total
1194. In case of involvement of 3 – 6 anatomic regions in inflammatory process the peritonitis is named:
- A. * diffuse
 - B. focal
 - C. local
 - D. general
 - E. total
1195. In diffuse peritonitis the inflammatory process spreads on anatomic regions:
- A. * more than 6
 - B. from 2 to 3
 - C. from 3 to 6
 - D. 1
 - E. 9
1196. In interintestinal abscess used such medical tactic:
- A. * opening of the abscess with drainage
 - B. detoxication therapy
 - C. antiinflammatory therapy
 - D. puncture of the abscess with drainage
 - E. antibiotics
1197. In paraappendicular abscess used such operative access:
- A. * retroperitoneal
 - B. McBurney
 - C. pararectal
 - D. middle
 - E. Volkovich-Dyakonov
1198. In peritonitis in intestine prevails:
- A. * secretion
 - B. exudation
 - C. absorption
 - D. resorbtion
 - E. excretion
1199. In peritonitis the development of polyorganic insufficiency results from the lesion of:
- A. * parenchymatous organs
 - B. respiratory organs
 - C. connective tissue organs
 - D. hollow organs
 - E. genitourinary organs
1200. In peritonitis the first organ which is affected by the toxins from a parietal peritoneum is:
- A. * lungs
 - B. spleen

- C. kidneys
 - D. liver
 - E. heart
1201. In peritonitis the II degree of endotoxemia requires:
- A. * intracorporeal methods of detoxication
 - B. extracorporeal methods of detoxication
 - C. programmed laparotomy
 - D. peritoneal lavage
 - E. peritoneal dialysis
1202. In peritonitis the main cause of metabolic disturbances is:
- A. * hypoxia
 - B. venous dysfunction
 - C. acidosis
 - D. alkalosis
 - E. arterial dysfunction
1203. In peritonitis the most optimal volume of the operation is:
- A. * minimal
 - B. maximal
 - C. complex
 - D. extended
 - E. radical
1204. In peritonitis the toxins from a visceral peritoneum affect first of all:
- A. * liver
 - B. spleen
 - C. kidneys
 - D. lungs
 - E. heart
1205. In peritonitis the toxins spread from a visceral peritoneum through:
- A. * portal vein
 - B. superior cava vein
 - C. inferior cava vein
 - D. hepatic vein
 - E. splenic vein
1206. In peritonitis, the formation of the pathological "third space" takes place through the sequestration of the fluid into:
- A. * abdominal cavity, retroperitoneal space
 - B. lumen of intestine, muscles
 - C. lumen of intestine, parenchymatous organs
 - D. parenchymatous organs, muscles
 - E. lumen of intestine, subcutaneous tissue
1207. In subphrenic abscess the retraction of intercostal spaces during deep breath in is the sign:
- A. * Litten's
 - B. De Gardin's
 - C. De Cervan's
 - D. Dushen's
 - E. Senator's

1208. In the case of operation for acute peritonitis performed:
- A. * wide laparotomy
 - B. laparostomy
 - C. microlaparotomy
 - D. laparocentesis
 - E. laparotomy after Volkovich-Dyakonov
1209. In the widespread forms of peritonitis after the resection of the bowel the most optimal operation is:
- A. * Formation of stoma
 - B. anastomosis " end to side "
 - C. collateral anastomosis
 - D. anastomosis " side to side "
 - E. anastomosis " end to end "
1210. In what area of stomach practically never is not origin of ulcers, or it is extraordinarily rarely?
- A. small curvature of stomach;
 - B. back wall of stomach, nearer to small curvature;
 - C. large curvature of stomach
 - D. * cardiac part of stomach;
 - E. pylorus.
1211. In what vein is a venous outflow carried out in from a stomach?
- A. * V. Portae;
 - B. V. odd;
 - C. V. pair;
 - D. V. overhead hollow;
 - E. V. lower hollow;
1212. Interintestinal abscesses complicates as a rule:
- A. * by the diffuse peritonitis, intestinal fistula, obstruction, pilephlebitis
 - B. by the diffuse peritonitis intestinal fistula, ulcer, pilephlebitis
 - C. by the diffuse peritonitis, intestinal fistula, ulcer, gangrene
 - D. By the diffuse peritonitis, intestinal fistula, ulcer, phlegmon
 - E. By the diffuse peritonitis, intestinal fistula, ulcer, paraproctitis
1213. Interintestinal abscesses formed after peritonitis are named:
- A. * residual
 - B. chronic
 - C. recurrent
 - D. remittent
 - E. acute
1214. Large ulcer is an ulcer measuring
- A. 1-4 cm
 - B. 1-3 cm
 - C. 3-5 cm
 - D. 2- 6 cm
 - E. * 2-3 cm
1215. Late subphrenic abscesses arise up as a rule after:
- A. * 30-60 days
 - B. 10-15 days

- C. 15-20 days
 - D. 7-10 days
 - E. 60-90 days
1216. Little ulcer it is an ulcer measuring
- A. * to 0,5 cm
 - B. 0,5-1 cm
 - C. to 1,0 cm
 - D. 3 to 1,5 cm
 - E. 0,5-1,5 cm
1217. Low virulence of microbe flora on the background of normal reactivity of the organism predetermines the peritonitis:
- A. * focal
 - B. diffuse
 - C. local
 - D. total
 - E. general
1218. Meets the most frequent localization bleeding the digestive tract is
- A. gullet;
 - B. stomach;
 - C. rectum;
 - D. * duodenum;
 - E. colon
1219. Melena is
- A. black designed chair
 - B. * black liquid tarry chair
 - C. a discoloured liquid excrement
 - D. foamy stinking emptying of black
 - E. an excrement designed veined blood
1220. Melena is a characteristic sign
- A. * bleeding ulcer
 - B. for cicatrical-ulcerous pylorus stenosis
 - C. perforated ulcers
 - D. penetration ulcers
 - E. malignization ulcers
1221. Mesotelocytes of peritoneum are located in such layer:
- A. * superficial
 - B. deep
 - C. middle
 - D. vascular
 - E. nervous
1222. Most informing method at a bleeding ulcer
- A. survey sciagraphy the organs of abdominal region
 - B. * EFGDS
 - C. sciagraphy the stomach with contrasting
 - D. Sonography
 - E. Laparoscopy

1223. Name classic complications of ulcerous illness
- A. bleeding, pylorostenosis, second pancreatitis, malignization, perforation
 - B. * perforation, penetration, bleeding, pylorostenosis, malignization
 - C. malignization, pylorostenosis, penetration, anaemia, perforation
 - D. bleeding, perforation, second pancreatitis, anaemia, malignization
 - E. perforation, peritonitis, pancreatitis, bleeding, penetration
1224. Name correct classification of pelvic abscesses:
- A. * recto-uterine, vesico-rectal, paravesical, retrorectal
 - B. recto-uterine, ischio-rectal, pelviorectal, retrorectal
 - C. recto-uterine, vesico-rectal, pelviorectal, retrorectal
 - D. recto-uterine, paravesical, pelviorectal, retrorectal
 - E. recto-uterine, paravesical, ischio-rectal, retrorectal
1225. Name etiologic classification of peritonitis:
- A. * traumatic, postoperative, perforating, inflammatory
 - B. lymphogenous, postoperative, perforating, inflammatory
 - C. contact, postoperative, perforating, inflammatory
 - D. reactive, postoperative, perforating, inflammatory
 - E. hematogenous, postoperative, perforating, inflammatory
1226. Nasogastrintestinal intubation in peritonitis is used for:
- A. * decompression of intestine
 - B. relaxation of intestine
 - C. enteral feeding
 - D. compression of intestine
 - E. stimulation of intestine
1227. Operating access at operations on a stomach
- A. * Upper-middle laparotomy
 - B. Lower-middle laparotomy
 - C. Pararectum access
 - D. Volokovich-Dyakonov's access
 - E. Pfanenhtil's access
1228. Pain in peritonitis is caused by the lesion of:
- A. * parietal peritoneum
 - B. anterior abdominal wall
 - C. back abdominal wall
 - D. internal organs
 - E. visceral peritoneum
1229. Painful, dense infiltrate in the abdomen determined by palpation are the signs of the abscess:
- A. * interintestinal
 - B. retrocecal
 - C. subphrenic
 - D. subhepatic
 - E. pelvic
1230. Patient with gastroenteric bleeding in house is necessary
- A. * To send a patient in surgical permanent establishment
 - B. To appoint rest, enter Cacl, vicasol
 - C. To wash a stomach, appoint a cold, rest of supervision

- D. To send a patient in a therapeutic gastroenterology separation
 - E. A right answer absents
1231. Percussion sign of subphrenic abscess:
- A. * expanding of hepatic dullness
 - B. diminishing of hepatic dullness
 - C. absence of hepatic dullness
 - D. impaired hepatic dullness
 - E. tympanic sound over the liver
1232. Peritonitis is treated:
- A. * urgent operation
 - B. antibiotic therapy
 - C. detoxication therapy
 - D. no treatment required
 - E. conservative therapy
1233. Peritonitis resulting from surgical diseases, damages is called:
- A. * secondary
 - B. residual
 - C. primary
 - D. chronic
 - E. recurrent
1234. Pleural, retropleural operative accesses are used for the drainage of the abscess:
- A. * back subphrenic
 - B. subnephral
 - C. subhepatic
 - D. superior subphrenic
 - E. anterior subhepatic
1235. Polyorganic insufficiency is the main cause of the death of patients of:
- A. * peritonitis
 - B. cholecystitis
 - C. ulcers
 - D. myocardial infarction
 - E. appendicitis
1236. Preoperative preparation of patients with acute peritonitis must be:
- A. * individual and lasts not more than 2 hours
 - B. complex and lasts not more than 5 hours
 - C. depending on the patients condition to the complete correction of the vital functions
 - D. complex and to last not more than 6 hours
 - E. individual and lasts not more than 8 hours
1237. Programed laparapertion is:
- A. * formation of the provisional sutures on the wound with a further revision and sanation of abdominal cavity
 - B. leaving of open wound with its washing by antiseptics
 - C. suturing only of peritoneum with a further revision and sanation of abdominal cavity
 - D. suturing only of aponeurosis with a further revision and sanation of abdominal cavity
 - E. suturing of wound with a further revision of abdominal cavity
1238. Radical operation at a bleeding gastric ulcer and duodenum consists in

- A. sewing vessels on a draught;
 - B. * vagotomy or resection the stomach;
 - C. sewing vessels in an ulcer;
 - D. gastroenteroanastomosis;
 - E. all answers are faithful
1239. Rational operative access in peritonitis is:
- A. * median laparotomy
 - B. lower-middle laparotomy
 - C. upper-middle laparotomy
 - D. pararectal
 - E. lumbar
1240. Rectal infiltrate with fluctuation is determined in:
- A. * pelvic abscess
 - B. appendicular infiltrate
 - C. appendicular abscess
 - D. pelvic infiltrate
 - E. iliac abscess
1241. Relative absolute indication to operative treatment ulcerous illness is
- A. * penetration of ulcer
 - B. ulcerous anamnesis more than 15 years
 - C. malignization ulcers
 - D. perforation of ulcer
 - E. relapses more than 3 times per a year
1242. Resection of stomach by Bilrot II belongs to
- A. * radical operation
 - B. palliative operation
 - C. draining operations
 - D. organ protect operation
 - E. does not belong to any group
1243. Selective proximal vagotomy belongs to
- A. palliative
 - B. draining
 - C. * organ protect operation
 - D. resection
 - E. does not belong to any group
1244. Signs of stable hemostasis
- A. * absence blood in a stomach and duodenum bulb;
 - B. presence the light blood and faltungs of blood in a stomach;
 - C. profluvium blood from a vessel;
 - D. all answers correct;
 - E. all answers are not correct
1245. Signs of unstable hemostasis
- A. * the pulsation of vessel is determined;
 - B. the bottom ulcer is covered a fibrin;
 - C. profluvium blood from a vessel;
 - D. all answers are correct;
 - E. all answers are not correct.

1246. Subphrenic space is limited:
- A. * by a diaphragm, transverse colon, walls of the abdomen
 - B. by a diaphragm, small intestine, walls of the abdomen
 - C. by a diaphragm, gastro-colic ligament, walls of the abdomen
 - D. by a diaphragm, liver, walls of the abdomen
 - E. by a diaphragm, small omentum, walls of the abdomen
1247. Such stages of peritonitis are distinguished:
- A. * reactive, toxic, terminal
 - B. reactive, toxic, serous
 - C. toxic, fibrinous, terminal
 - D. acute, fibrinous, terminal
 - E. shock, toxic, terminal
1248. The recession between rectum and uterus is the space of:
- A. * Douglas
 - B. Dushen's
 - C. Dragsten's
 - D. Dumbadze
 - E. De Cervan's
1249. The recession between urinary bladder and rectum is named the space of:
- A. * Douglas
 - B. Dushen's
 - C. Dragsten's
 - D. Dumbadze
 - E. De Cervan's
1250. The abdominal cavity is named the space between:
- A. * anatomic structures which contain organs and tissues
 - B. peritoneum and abdominal wall
 - C. parietal and visceral peritoneum
 - D. organs and abdominal wall
 - E. diaphragm and pelvis
1251. The abscess of abdominal cavity is limited at first:
- A. * by demarcation bulwark from leucocytes
 - B. by demarcation bulwark from lymphocytes
 - C. by demarcation bulwark from fibroblasts
 - D. by demarcation bulwark from monocytes
 - E. by pyogenic membrane
1252. The abscess of Douglas is localized in space:
- A. * recto-vesicle
 - B. paravesicle
 - C. retrorectal
 - D. antevesicle
 - E. recto-colica
1253. The abscesses of abdominal cavity are divided on:
- A. * subphrenic, pelvic, interintestinal
 - B. subphrenic, rectal, subhepatic
 - C. subphrenic, interintestinal, subhepatic

- D. subphrenic, rectal, subhepatic
 - E. supraphrenic, pelvic, interintestinal
1254. The absence of somatic innervation of pelvic peritoneum in peritonitis predetermines:
- A. * The absence of muscular tension of the abdomen
 - B. The swelling of the abdomen
 - C. The wooden abdomen
 - D. The rigidity of muscles of anterior abdominal wall
 - E. The retraction of the abdomen
1255. The absorbal ability of the diaphragm predetermines formation of abscess:
- A. * subphrenic
 - B. interintestinal
 - C. pelvic
 - D. appendicular
 - E. supraphrenic
1256. The base of pathogenesis of the focal peritonitis is:
- A. * increased activity of the coagulative system
 - B. absence of activity of the coagulative system
 - C. impaired activity of the coagulative system
 - D. activity of the coagulative system is not changed
 - E. presence of activity of the coagulative system
1257. The cavity between organs and abdominal wall is called:
- A. * peritoneal
 - B. abdominal
 - C. pelvic
 - D. retroperitoneal space
 - E. interintestinal
1258. The clinic of pelvic abscess is often accompanied :
- A. * by absence of tension of anterior abdominal wall
 - B. by tension of anterior abdominal wall
 - C. by painfulness of anterior abdominal wall
 - D. by a wooden abdomen
 - E. swelling of the abdomen
1259. The connective tissue membrane has such abscess of the abdominal cavity:
- A. * formed
 - B. primary
 - C. early
 - D. not formed
 - E. loose
1260. The connective tissue membrane is formed in peritonitis:
- A. * secondary focal
 - B. diffuse
 - C. general
 - D. primary focal
 - E. total
1261. The diarrhea often is the sign of such abscess:
- A. * pelvic

- B. paraappendicular
 - C. iliac
 - D. appendicular
 - E. retroperitoneal
1262. The difference of more than 2° N between the morning and evening temperatures occurs in:
- A. * subphrenic abscess
 - B. diffuse peritonitis
 - C. general peritonitis
 - D. subphrenic infiltrate
 - E. local peritonitis
1263. The disturbance of protein metabolism in peritonitis is represented by:
- A. * diminishing of albumins, increasing of globulins
 - B. increasing of albumins and globulins
 - C. increasing of albumins, diminishing of globulins
 - D. diminishing of albumins and globulins
 - E. lbumins, globulins is not changed
1264. The draining of Douglas space is performed through:
- A. * rectum
 - B. foramen obturatorium
 - C. perineum
 - D. sacrum region
 - E. anterior abdominal wall by retroperitoneal
1265. The euphoric state of patient in peritonitis arises up as a rule in the stage:
- A. * II
 - B. I
 - C. III
 - D. IV
 - E. V
1266. The focal peritonitis is limited by such anatomic structures:
- A. * omentum, mesentery and the wall of bowel
 - B. liver, adhesions
 - C. appendix, cecum
 - D. adhesions, vessels, the wall of bowel
 - E. adhesions, round ligament of liver
1267. The frequency of what pathogenic flora increases in peritonitis:
- A. * anaerobic nonclostridial
 - B. aerobic clostridial
 - C. aerobic nonclostridial
 - D. anaerobic clostridial
 - E. aerobic
1268. The general surface of peritoneum is:
- A. 2 - 3 m²
 - B. 1 - 2 m²
 - C. 0,5 - 1 m²
 - D. 3 - 4 m²
 - E. 5 - 6 m²

1269. The immobility of back bone at walking of patient in peritonitis is the sign:
- A. * Senator's
 - B. Dushen's
 - C. Lithen's
 - D. Mussi
 - E. Voskresensky's
1270. The immobility of back bone in a subphrenic abscess is the sign:
- A. * Senator's
 - B. Dushen's
 - C. Lithen's
 - D. Sitkovsky's
 - E. Spasokukotsky's
1271. The increased peristalsis is characteristic for such abscess:
- A. * interintestinal
 - B. subphrenic
 - C. subhepatic
 - D. retrocecal
 - E. subsplenic
1272. The infection in peritonitis in the most cases is:
- A. * aerobico-anaerobic
 - B. anaerobic
 - C. nonclostridial
 - D. clostridial
 - E. aerobic
1273. The infection in peritonitis in the most cases represented by:
- A. * E. coli
 - B. Bacteroids
 - C. Pneumococcus
 - D. Pseudomonas aeruginosa
 - E. Protheus
1274. The interintestinal abscesses formed near the primary source of infection are named:
- A. * primary
 - B. lymphogenous
 - C. metastatic
 - D. hematogenous
 - E. secondary
1275. The involvement of epigastric region during breath in and its outpouching during breath out in peritonitis is the sign:
- A. * Dushen's
 - B. Lithen's
 - C. Senator
 - D. Mussi
 - E. Voskresensky's
1276. The irradiation of pain in the lumbar region is characteristic for such abscess:
- A. * subphrenic
 - B. retrocecal
 - C. retroperitoneal

- D. appendicular
 - E. subhepatic
1277. The main cause of the development of peritonitis is:
- A. * infection
 - B. trauma
 - C. shock
 - D. impaired immunity
 - E. impaired resistance
1278. The main spread of infection in peritonitis is:
- A. * hematogenous and lymphogenous
 - B. exogenous
 - C. lymphogenous
 - D. hematogenous
 - E. endogenous
1279. The middle thickness of peritoneum is:
- A. * 0,7 – 1,1 mm.
 - B. 0,5-1,0 mm.
 - C. 0,3 – 0,5 mm.
 - D. 1 - 2 mm.
 - E. 2 - 3 mm.
1280. The morphologic structure of peritoneum:
- A. * connective tissue
 - B. fibrous
 - C. serous
 - D. visceral
 - E. parietal
1281. The most information instrumental method of diagnostics of peritonitis is:
- A. * laparoscopy
 - B. ultrasound examination
 - C. roentgenoscopy
 - D. laparocentesis
 - E. computer tomography
1282. The most informative additional method of examination in peritonitis is:
- A. * plain X-ray
 - B. irrigography
 - C. esophagogastroscopy
 - D. barium swallow
 - E. coprologic examination
1283. The most informative instrumental method of diagnostics of peritonitis is:
- A. * laparoscopy
 - B. ultrasound examination
 - C. thermography
 - D. esophagogastroscopy
 - E. barium swallow
1284. The most informative instrumental method of diagnostics of peritonitis is:
- A. * laparocentesis

- B. Rectoscopy
 - C. rheovasography
 - D. thermography
 - E. roentgenoscopy
1285. The nosotropic mechanisms bleedingness at ulcerous illness is
- A. * all answers are correct.
 - B. permanent hyperemia all system of stomach
 - C. different degree dystrophy of superficial layers the mucus shell
 - D. accumulation the central mucopolysaccharides
 - E. hypoplastic, dystrophic processes
1286. The organs are fixed around the site of inflammation in the focal peritonitis by:
- A. * fibrin
 - B. exudate
 - C. transsudate
 - D. prothrombin
 - E. thrombin
1287. The painfulness during palpation in a supraclavicular region in subphrenic abscess is the sign:
- A. * Mussi-Georgievsky
 - B. Bartomier-Mikhelson's
 - C. Yaure-Rozanov's
 - D. Shchotkin-Blumberg's
 - E. Rovsing's
1288. The painfulness of anterior wall of rectum is the sign:
- A. * Kulenkampf's
 - B. Krymov's
 - C. Kocher
 - D. Culen's
 - E. Crown's
1289. The paralysis of microcirculation in peritonitis develops in such stage:
- A. * terminal
 - B. toxic
 - C. reactive
 - D. acute
 - E. subacute
1290. The participation of anterior abdominal wall in the act of breathing in peritonitis:
- A. * does not take part
 - B. takes part partly
 - C. takes part
 - D. takes part doubtfully
 - E. takes part fastly
1291. The peritonitis caused by the contamination of the peritoneum by hematogenous and lymphogenous way is called:
- A. * primary
 - B. chronic
 - C. acute
 - D. secondary

- E. recurrent
1292. The peritonitis develops in such concentration of microorganisms in 1 ml. of exudate:
- A. * 1?107
 - B. 1?103
 - C. 1?105
 - D. 1?101
 - E. 1?109
1293. The peritonitis of 3? degree requires:
- A. * extracorporal methods of detoxication
 - B. laparocentesis
 - C. programmed laparostomy
 - D. laparoscopy
 - E. lavage
1294. The peritonitis of IV degree requires:
- A. * programmed laparostomy
 - B. laparoscopy
 - C. lavage
 - D. extracorporal methods of detoxication
 - E. laparocentesis
1295. The retraction of epigastric region during breath in and its outpouching during breath out in subphrenic abscess is the sign:
- A. * Dushen's
 - B. Lithen's
 - C. De Cervan's
 - D. De Gardin's
 - E. Senator's
1296. The secretory function stomach is carried out the next membrane of stomach
- A. * mucous membrane
 - B. internal muscular layer
 - C. serosal
 - D. mucous submembrane
 - E. external layer
1297. The separation by tissue structures parallel to the development of inflammatory process leads to the form of peritonitis:
- A. * the primary focal
 - B. the secondary diffuse
 - C. diffuse
 - D. the secondary focal
 - E. the primary diffuse
1298. The signs of peritoneal irritation are absent in such abscess:
- A. * pelvic
 - B. paraappendicular
 - C. interintestinal
 - D. subphrenic
 - E. appendicular
1299. The stages of the operative treatment of peritonitis:

- A. * liquidation of the cause, sanation, drainage of the abdominal cavity
 - B. laparotomy, sanation, drainage of the abdominal cavity
 - C. liquidation of the cause, drainage of abdominal cavity, suturing of wound
 - D. laparotomy, liquidation of the cause, drainage of abdominal cavity
 - E. liquidation of the cause, sanation
1300. The subphrenic abscess is treated by:
- A. * opening and drainage of abscess
 - B. puncture, washing out by antiseptics
 - C. resection of abscess
 - D. opening of abscess, washing out by antiseptics
 - E. puncture
1301. The subphrenic abscesses are caused:
- A. * by negative pressure during excursion of diaphragm
 - B. by the inflammatory reaction of diaphragm
 - C. by the presence of free space
 - D. by positive pressure during excursion of diaphragm
 - E. by position of patient
1302. The tenesmi often are the signs of such abscess:
- A. * pelvic
 - B. paraappendicular
 - C. iliac
 - D. retroperitoneal
 - E. appendicular
1303. The tense resistance of anterior abdominal wall in peritonitis is the sign:
- A. * Mondor's
 - B. Voskresensky's
 - C. Kulenkampf's
 - D. Shchotkin-Blumberg
 - E. Pasternatsky's
1304. The toxic phase of peritonitis above all things is caused by:
- A. * endotoxins
 - B. exotoxins
 - C. toxins
 - D. polytoxins
 - E. monotoxins
1305. The toxins in peritonitis spread from a parietal peritoneum through:
- A. * inferior cava vein
 - B. superior cava vein
 - C. portal vein
 - D. hepatic vein
 - E. splenic vein
1306. The vascular layer of peritoneum is located under:
- A. * superficial
 - B. serous
 - C. deep
 - D. fibrous
 - E. nervous

1307. The wooden abdomen in peritonitis is characteristic for the stage:
- A. * first
 - B. third
 - C. fourth
 - D. second
 - E. fifth
1308. To absolute indication to operative interference at ulcerous illness does not belong
- A. * scarry-ulcerous stenosis
 - B. perforation of ulcer
 - C. profuse bleeding
 - D. diameter ulcer a more than 3 cm
 - E. bleeding what does not stopped with conservative
1309. To the focal peritonitis belongs:
- A. * infiltrate of abdominal cavity
 - B. diffuse, limited
 - C. total, unlimited
 - D. total
 - E. general
1310. To the gastric – intestinal bleeding of un ulcerous etiology belong
- A. * Mallory-Weiss syndrome;
 - B. hemorrhagic erosive gastritis;
 - C. diseases by Randyu – Oslera – Vebera;
 - D. Menetrie's sing;
 - E. all answers are correct.
1311. To the local peritonitis belongs:
- A. * abscess
 - B. diffuse
 - C. general
 - D. furunculus
 - E. total
1312. Udin's sing at a perforated ulcer is
- A. * feeling at palpation shove the gases which penetrate through the perforated opening
 - B. dulling perforated sound in the lateral departments of stomach
 - C. disappearance of hepatic dullness
 - D. irradiation pain in a shoulder or shoulder-blade
 - E. sickliness the back vault of vagina
1313. Vasoconstriction of microcirculation in peritonitis develops in such stage:
- A. * reactive
 - B. toxic
 - C. terminal
 - D. acute
 - E. subacute
1314. Vasodilatation of microcirculation in peritonitis develops in such stage:
- A. * toxic
 - B. reactive
 - C. terminal

- D. acute
 - E. subacute
1315. Vomiting coffee-grounds is a characteristic sign
- A. * bleeding ulcer
 - B. penetrative ulcers
 - C. perforated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorus stenosis
1316. Vomiting in peritonitis:
- A. * does not relief
 - B. relief
 - C. does not change the state of patient
 - D. deteriorates the state of patient
 - E. improves the state of patient
1317. Vomiting what arose up in 4-6 hours after eating characteristic for
- A. chronic alcoholic gastritis
 - B. cancer and ulcers of cardia
 - C. * pylorus ulcers
 - D. achalasia of gullet
 - E. ulcer and cancer the body of stomach
1318. What are the changes, which don't require the drainage of abdominal cavity in peritonitis:
- A. * A presence of inflammatory changes of the peritoneum + absence of exudate
 - B. intestinal content in abdominal cavity + possibility of anastomosis leakage
 - C. presence of turbid exudate + presence of pus in abdominal cavity + presence of inflammatory infiltrate
 - D. inflammatory changes of peritoneum + presence of turbid exudate
 - E. inflammatory changes of peritoneum + presence of pus in abdominal cavity F. a presence of pus in abdominal cavity + infection of abdominal cavity
1319. What colouring of chair is most characteristic for bleeding from the ulcer of stomach and duodwnum?
- A. * Tarry excrement
 - B. Presence on the formed excrement of strokes of red blood
 - C. Littlechanged blood in an excrement
 - D. Excrement of the raspberry colouring with the admixtures of mucus
 - E. Acholic excrement
1320. What complication the ulcerous illness of stomach is most characteristically for the patients of elderly and senile age
- A. perforation
 - B. perforation + bleeding
 - C. pylorus stenosis
 - D. malignization + penetration
 - E. * bleeding
1321. What external signs are characteristic for the profuse bleeding from a gastric ulcer?
- A. Vomiting by the littlechanged blood, excrement of the raspberry colouring
 - B. * Vomiting by the littlechanged blood, tarry darkly-cherry chair
 - C. Vomiting by a complete mouth by dark blood with clots, black formed excrement

- D. Vomiting on the type of "coffee-grounds", presence on the formed incandescence of strokes of red blood
 - E. Tarry darkly-cherry chair
1322. What from preparations has the expressed bacteriostatic action on Helicobacter pyloris
- A. * trichopol
 - B. Liciviroton
 - C. oxiferiskorbon
 - D. atropine
 - E. pirinzsipin
1323. What from the transferred operations does not belong to organ protective
- A. trunk vagotomy
 - B. * resection by Bilrot II
 - C. selective vagotomy
 - D. selective proximal vagotomy
 - E. the all transferred does not belong
1324. What from the transferred operations on the stomach organ protective is
- A. * selective proximal vagotomy
 - B. resection by Bilrot I
 - C. resection by Bilrot II
 - D. gastrectomy
 - E. all are transferred
1325. What hormones undertake the protective operating on the mucous membrane of stomach, except for
- A. * ACTH
 - B. epidermal factor of growth
 - C. prostaglandin E
 - D. estrogens
 - E. STH
1326. What is the treatment tactic in pelvic abscess?
- A. * opening and drainage of the abscess,
 - B. antibiotics
 - C. antiinflammatory therapy
 - D. puncture of the abscess, drainage
 - E. detoxication therapy
1327. What is the treatment tactic in subphrenic abscess?
- A. * operative treatment
 - B. antiinflammatory medicines
 - C. conservative treatment
 - D. antibiotics
 - E. contemplate tactic
1328. What is the volume of fluid contained in peritoneal cavity?
- A. * 10 ml.
 - B. 100 ml.
 - C. 30 ml.
 - D. 40 ml.
 - E. 50 ml.

1329. What kind of abdomen is characteristic for the reactive stage of peritonitis?
- A. * wooden
 - B. soft
 - C. bloated
 - D. rigidit
 - E. retracted
1330. What localization of ulcer is most characteristic for the patients of elderly and senile age
- A. * cardial department of stomach
 - B. overhead third of gullet
 - C. lower third of gullet
 - D. bulb of duodewnum
 - E. small curvature
1331. What method diagnostics hte ulcerous illness most informing
- A. * esophagogastroduodenoscopy
 - B. analysis of excrement on the hidden blood
 - C. X-ray
 - D. global analysis of blood
 - E. research of gastric secretion
1332. What method is it orientation possible to define the volume of hemorrhage on at the acute gastroenteric bleeding?
- A. On maintenance red corpuscles, haemoglobin, Ht, thrombocytes
 - B. On blood volume
 - C. * On an arteriotony, pulse, state of patient
 - D. On a globular volume
 - E. On the level of thrombocytes
1333. What phase of peritonitis lasts after 72 hours?
- A. * terminal
 - B. hemodynamic
 - C. polyorganic
 - D. toxic
 - E. reactive
1334. What phase of peritonitis lasts for 24 hours?
- A. * reactive
 - B. toxic
 - C. terminal
 - D. hemodynamic
 - E. polyorganic
1335. What phase of peritonitis lasts from 24 to 72 hours?
- A. * toxic
 - B. hemodynamic
 - C. reactive
 - D. terminal
 - E. polyorganic
1336. What preparation does behave to blocker H2-retseptors?
- A. * tavegil
 - B. obzidan
 - C. hystdol

- D. cerucal
 - E. oraza
1337. What preparation does behave to blocker of muscarine receptors of coating cages?
- A. cymetidin
 - B. eglonin
 - C. * gastocepini
 - D. etimsiloli
 - E. vinylin
1338. What preparations, except for other properties, own yet and a bacteriostatic effect on *Helicobacter pylori*
- A. * all are transferred preparations
 - B. Almagel
 - C. Vinylin
 - D. De-nol
 - E. Claritromycin
1339. What products are recommended in the diet of № 1?
- A. * hen in a steam kind
 - B. pancakes
 - C. raw egg-white
 - D. bread rye fresh
 - E. acute cheeses
1340. What stage of peritonitis is characterised besides general manifestation the clinic of intestinal obstruction?
- A. * second
 - B. first
 - C. third
 - D. fourth
 - E. fifth
1341. What syndrome is characteristic for hemorrhagic erosive gastritis?
- A. * ulcerous
 - B. hemorrhagic;
 - C. pain;
 - D. all answers are correct;
 - E. all answers are not correct.
1342. What time urgent operations are executed at acute bleeding
- A. * 6 – 12 hours;
 - B. 6 – 10 hours;
 - C. 6 – 8 hours
 - D. 6 – 14 hours;
 - E. 6 – 20 hours
1343. What violation of mineral exchange is characteristic for patients with ulcerous illness of stomach and intestine
- A. hypocalcemia
 - B. * hypokaliemia
 - C. Hyponatremia
 - D. Hypercalcinemia
 - E. hyperkaliemia

1344. When apply Teylor's method at ulcerous illness
- A. * at conservative treatment perforated ulcers
 - B. at conservative treatment sanguifluous ulcers
 - C. at conservative treatment penetration ulcers
 - D. at conservative treatment malignization ulcers
 - E. at conservative treatment of cicatrical pylorostenosis
1345. Which stage of peritonitis is characterized by endotoxication?
- A. * toxic
 - B. terminal
 - C. reactive
 - D. hemodynamic
 - E. polyorganic
1346. Which stage of peritonitis is characterized by infection generalization?
- A. * terminal
 - B. toxic
 - C. hemodynamic
 - D. reactive
 - E. polyorganic
1347. Which stage of peritonitis is characterized by the reaction of the organism on infecting of abdominal cavity?
- A. * reactive
 - B. toxic
 - C. terminal
 - D. polyorganic
 - E. hemodynamic
1348. A patient 40 years old, suffered ulcerous diseases of stomach. Last 2 days the pain became less intensive, but weakness and dizziness were appeared. Rose from a bed and lost consciousness. Pale. There are insignificant pains in epigastrium. It is
- A. Combination perforation with bleeding
 - B. Perforation
 - C. Malignization of ulcer
 - D. Stenosis of ulcer
 - E. * Gastroenteric bleeding
1349. Absolute indication to operative treatment the ulcerous illness is
- A. heavy pain syndrome
 - B. * perforation of ulcer
 - C. relapses more than 2 one time per a year
 - D. ulcerous anamnesis more than 10 years
 - E. giant ulcers
1350. Absolute indication to operative treatment the ulcerous illness is
- A. * voluminous bleeding
 - B. callous ulcers
 - C. relapses more than 2 one time per a year
 - D. ulcerous anamnesis more than 10 years
 - E. heavy pain syndrome
1351. Absolute indication to operative treatment the ulcerous illness is

- A. ulcerous anamnesis more than 10 years
 - B. * bleeding what do not stopped with conservative
 - C. perforation ulcer in anamnesis
 - D. heavy pain syndrome
 - E. relapses more than 3 times per a year
1352. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. ulcerous anamnesis more than 10 years
 - C. relapse ulcer after the resection of stomach
 - D. relapses more than 3 times per a year
 - E. * cicatrical-ulcerous stenosis of pylorus
1353. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. * malignization ulcers
 - C. ulcerous anamnesis more than 10 years
 - D. heavy pain syndrome, proof heartburn
 - E. relapse ulcer after vagotomy
1354. Absolute sign of unstable hemostasis
- A. * profluvium blood from a vessel;
 - B. absence blood in a stomach and bulb of duodenum;
 - C. presence light blood and faltungs of blood in a stomach;
 - D. all answers are correct;
 - E. all answers are not correct
1355. Acquire hernia could be all, except:
- A. Neurological
 - B. Traumatic
 - C. Recurrent
 - D. Postoperative
 - E. * Post-natal
1356. Acute ileus arises up at presence in the hernia sac:
- A. Urinary bladder
 - B. Salpinx
 - C. Omentum
 - D. Subcutaneous fatty tissue
 - E. * Loops of bowel
1357. After the method of Kukudzhanov it is performed hernioplasty of:
- A. Umbilical hernia
 - B. Femoral and inguinal hernias
 - C. Epigastroceles
 - D. Femoral hernia
 - E. * Inguinal hernia
1358. After the method of Meyo it is performed hernioplasty of:
- A. Femoral and inguinal hernias
 - B. Epigastroceles
 - C. Femoral hernia
 - D. Inguinal hernia
 - E. * Umbilical hernia

1359. After what operation at ulcerous illness the natural arcade of meal is saved on a digestive tract
- A. Valter-Braun's gastroenterostomy
 - B. not saved after any operation
 - C. resection by Bilrot II
 - D. * resection by Bil'rot I
 - E. saved after all transferred operations
1360. After what operation innervation of pyloric department of stomach is saved
- A. * selective vagotomy
 - B. barrel vagotomy
 - C. selective proximal vagotomy
 - D. at all transferred
 - E. not saved after all operations
1361. Any hernia of abdomen consists of:
- A. Hernia sack
 - B. Hernia sack and content
 - C. Hernia content
 - D. Hernia gate and hernia sack
 - E. * Hernia gate, hernia sack, hernia content
1362. At beginning bleeding from an ulcer
- A. * pain diminishes
 - B. pain increases
 - C. there is knife-like pain
 - D. character of pain does not change
 - E. girdle pain
1363. At bleeding emergency operative interferences are executed
- A. * to 3 hours
 - B. to 1,5 hour
 - C. to 6 hours
 - D. to 8 hours
 - E. 6 – 12 hours
1364. At III stage blood loss at the bleeding ulcer the patient loses
- A. over 1000 ml blood
 - B. * over 2000 ml blood
 - C. over 500 ml blood
 - D. over 2500 ml blood
 - E. over 1500 ml blood
1365. At III stage blood loss at the bleeding ulcer the patient loses
- A. more than 25 % blood volume
 - B. * more than 30 % blood volume
 - C. more than 20 % blood volume
 - D. more than 15 % blood volume
 - E. more than 35 % blood volume
1366. At incarcerated hernia after the dissection of hernia sack, the next manipulation is:
- A. Finish operation
 - B. Sequence of manipulations are not important

- C. To perform puncture of hernia sack and delete hernia water
 - D. To cut a incarceration ring
 - E. * To cut a hernia sack
1367. At incarceration hernia microcirculation disorders could be:
- A. In abdominal cavity
 - B. In a hernia gate
 - C. In a hernia sack
 - D. In a distal bowel
 - E. * In a proximal bowel
1368. At incarceration of diaphragmatic hernia more frequent arises up:
- A. Syndrome of respiratory insufficiency
 - B. Dyspepsia
 - C. Intoxication syndrome
 - D. Pain a syndrome
 - E. * Pain shock with violation of cardiac rhythm
1369. At incarceration of hernia the most deep changes arise up in:
- A. In all simultaneously
 - B. In the peritoneum
 - C. In the serosa
 - D. In the muscular tunic
 - E. * In the mucus tunic
1370. At left-side non-reducible femoral hernia is used:
- A. Methods of Martinov, Postempsky
 - B. Methods of Martinov, Zhirar, Spasokukotsky, Kimbarovsky
 - C. Methods of Bassini, Kukudzhanov, Postempsky
 - D. Methods of Sapezhko, Meyo
 - E. * Methods of Bassini, Rudzhi, Parlavecho
1371. At the duodenum ulceroperation of choice is
- A. * resection by Bilrot I
 - B. resection by Bilrot II
 - C. resection of duodenum
 - D. selective proximal vagotomy
 - E. sewing up of ulcer
1372. At the gastroenteric bleeding the middle degree of blood loss is diagnosed at next indexes
- A. Hb below 80 g/l
 - B. * Hb 80-100 g/l
 - C. red corpuscles below $2,5 \cdot 10^{12}/l$
 - D. red corpuscles of $3,5-4,0 \cdot 10^{12}/l$
 - E. Ht below 25%
1373. At the III item of activity hemostasis and III sage blood loss from the I – III sage blood loss indicated
- A. * urgent operations (6 – 12 hours);
 - B. emergency operations (to 3 hours);
 - C. exigent operations (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)

1374. At the V item activity of hemostasis and at the recurrent bleeding of the I – III item of blood loss indicated
- A. * emergency operations (to 3 hours);
 - B. urgent operations (6 – 12 hours);
 - C. exigent (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
1375. At ulcerous illness can a bleeding source be
- A. artery;
 - B. veins;
 - C. shallow vessels and ulcers;
 - D. all answers are not correct.
 - E. * all answers are correct
1376. Auscultative sign of presence in the hernia sack of loop of bowel:
- A. Drum shot
 - B. Noise of falling drop
 - C. Clang
 - D. Absence of peristaltic waves
 - E. * Presence of peristaltic waves
1377. Auscultative sign of presence in the hernia sack of omentum is:
- A. Drum shot
 - B. Noise of falling drop
 - C. Clang
 - D. Presence of peristaltic waves
 - E. * Absence of peristaltic waves
1378. Autoplastic methods of surgical treatment of femoral hernia:
- A. Method of Spasokukotsky
 - B. Method of Meyo
 - C. Method of Rudzhi
 - D. Methods of Lockwood and Abrazhanov
 - E. * Method Caravanov
1379. Bergman's sing is characteristic for
- A. * bleeding ulcer
 - B. for cicatrical-ulcerous pylorostenosis
 - C. perforated ulcers
 - D. penetration ulcers
 - E. malignization ulcers
1380. Berhtein's sing characteristic for
- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatrical-ulcerous pylorostenosis
1381. Bleeding ulcer, complicated blood loss III stage degrees, requires
- A. * blood and its components transfusions
 - B. transfusion of salt solutions
 - C. transfusion of colloid solutions

- D. transfusion of salt and colloid solutions
 - E. infusion therapy does not need
1382. Blood loss I stage characterized such indexes
- A. Ht 48-44, Hb 120
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 31-23, Hb 80
 - D. * Ht 38-32, Hb 100
 - E. Ht 44-40, Hb 110 /?
1383. Blood loss II stage characterized
- A. * Ht 23 and below, Hb 50 and below
 - B. Ht 31-23, Hb 80
 - C. Ht 44-40, Hb 110
 - D. Ht 48-44, Hb 120
 - E. Ht 48-44, Hb 120
1384. Blood loss III stage characterized a degree such indexes
- A. * Ht 31-23, Hb 80
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 38-32, Hb 100
 - D. Ht 44-40, Hb 110
 - E. Ht 48-44, Hb 120
1385. By Bassini method the plastic are performed:
- A. All of the listed hernia
 - B. Umbilical hernia
 - C. Only inguinal hernia
 - D. Only femoral hernia
 - E. * Inguinal and femoral hernia
1386. By Spasokukocky method treated:
- A. A method can be applied at all hernias
 - B. Umbilical hernia
 - C. Femoral hernia
 - D. Direct inguinal hernia
 - E. * Oblique inguinal hernia
1387. By the method of Postempsky it is performed hernioplasty of:
- A. Femoral and inguinal hernias
 - B. Epigastroceles
 - C. Femoral hernia
 - D. Umbilical hernia
 - E. * Inguinal hernia
1388. By the method of Sapezhko it is performed hernioplasty of:
- A. Femoral and inguinal hernias
 - B. Epigastroceles
 - C. Femoral hernia
 - D. Inguinal hernia
 - E. * Umbilical hernia
1389. Congenital inguinal hernia could be?
- A. Upper and lower

- B. Combined
 - C. Oblique and direct
 - D. Direct
 - E. * Oblique
1390. De-Cerven's sign is characteristic for
- A. bleeding ulcer
 - B. * perforated ulcers
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorostenosis
1391. Diet at bleeding gastric and duodenum ulcers
- A. * Meulengracht's
 - B. 1 by Pevznerom
 - C. 5 by Pevznerom
 - D. 15 by Pevznerom
 - E. 7 by Pevznerom
1392. Differential diagnostics of femoral hernia is performed with:
- A. Lymphadenitis
 - B. Inguinal hernia
 - C. Varicosity
 - D. Cold abscess
 - E. * All listed
1393. Disappearance or diminishing the pain with beginning of bleeding from an ulcer is
- A. * Bergman's sign
 - B. Spazarskiy's sign
 - C. Mendel's sign
 - D. De Keven's sign
 - E. Eleker's sign
1394. Duration of dynamic supervision if incarcerated hernia is replaced:
- A. 2 hours
 - B. 1 hour
 - C. 12 hours
 - D. 6 hours
 - E. * 24 hours
1395. Duration the period of primary shock at a perforated ulcer
- A. * 3-6 hours
 - B. 6-12 hours
 - C. 1-3 hours
 - D. 12-24 hours
 - E. 24-36 hours
1396. During Postempsky method:
- A. Forming of double-layer of white line of abdomen
 - B. Suturing of defect of anterior abdominal wall
 - C. Strengthening of posterior wall of inguinal channel
 - D. Strengthening of anterior wall of inguinal channel
 - E. * The closing of inguinal interval

1397. During retrograde incarceration:
- A. Large part of bowel is jammed
 - B. All of bowel is jammed
 - C. Only small part of bowel is jammed
 - D. Jammed part of loop which located in a hernia sack
 - E. * Jammed part of bowel, located in the abdominal cavity
1398. During what operation is performed suturing between the ligament of Kuper, by the vagina of direct muscle of abdomen and aponeurosis of transversal muscle:
- A. The plastic by Bassini
 - B. Method of Postempsky
 - C. Method of Martinov
 - D. Method of Spasokukotsky
 - E. * Method of Kukudzhanov
1399. Eleker's sign is characteristic for
- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatrical-ulcerous pylorostenosis
1400. Esophagogastroduodenoscopy can find out next changes in a stomach, except for
- A. tumours
 - B. ulcers
 - C. bleeding polypuses
 - D. erosions
 - E. * changes of evacuation function
1401. For a hernioplasty by skins materials is used:
- A. Method of Martinov
 - B. Method of Rudzhi
 - C. Method of Meyo
 - D. Method of Postempsky
 - E. * Method of Janov
1402. For bleeding ulcer characteristic sign is
- A. * pain in an epigastrium;
 - B. knife-like pain;
 - C. signs irritation of peritoneum;
 - D. presence fresh blood in incandescence
 - E. melena;
1403. For bleeding ulcer characteristically
- A. * melena
 - B. tension the muscles of front abdominal wall
 - C. Spazarskiy's sign
 - D. sickliness the back vault of vagina
 - E. irradiation pain in a shoulder or shoulder-blade
1404. For closing of hernia gate from the femoral side is used:
- A. Method of Spasokukocky
 - B. Method of Meyo
 - C. Method Caravanov

- D. Method of Rudzhi
 - E. * Methods of Lokvud and Abrazhanov
1405. For diaphragmatic hernia a typical symptom is:
- A. Negative cough sign
 - B. Nausea
 - C. Pain
 - D. Positive cough sign
 - E. * Feeling of grumbling in a thorax on the side of hernia
1406. For hernioplasty of wide femoral fascia is used:
- A. Method of Martinov
 - B. Method of Zhirar
 - C. Method of Postempsky
 - D. Method of Meyo
 - E. * Method of Kirschner
1407. For motion of disease ulcerous illness of middle weight characteristically
- A. development of complications
 - B. * relapses 1-2 times per a year
 - C. 4 and anymore relapses on a year
 - D. 5 and more relapses are on a year
 - E. 3 and anymore relapses on a year
1408. For perforated ulcer characteristically
- A. * tension the muscles of front abdominal wall
 - B. melena
 - C. vomiting by coffee-grounds
 - D. high intestinal impassability
 - E. vomiting stagnant gastric maintenance
1409. For pneumoperitoneum is characteristic symptom
- A. * Zhober's;
 - B. Khelatid's;
 - C. Podlag's;
 - D. Vigats's;
 - E. Udin's.
1410. For strengthening of anterior wall of inguinal channel is used:
- A. Method of Kukudzhanov
 - B. Method of Postempsky
 - C. Method of Bassini, Kukudzhanov
 - D. Method of Cherni, Ru
 - E. * Methods of Martinov, Zhirar, Spasokukotsky
1411. For strengthening of posterior wall of inguinal channel is used:
- A. Methods of Kirschner
 - B. Methods of Postempsky
 - C. Methods of Cherni, Ru
 - D. Methods of Martinov, Zhirara, Spasokukotsky
 - E. * Method of Bassini, Kukudzhanov
1412. For the heavy flow of ulcerous illness characteristically
- A. 2 and anymore relapses on a year

- B. * 3 and anymore relapses on a year
 - C. 4 and anymore relapses on a year
 - D. 5 and more relapses are on a year
 - E. 6 and more relapses are on a year
1413. For the heavy flow of ulcerous illness characteristically
- A. * development of complications
 - B. seasonal exacerbation more not frequent 1-2 times per a year
 - C. 1-2 relapse on a year
 - D. liquid, but protracted exacerbation
 - E. exacerbation duration more than 10 days
1414. From what department degestiyve tract developmentp more frequent than all the bleeding at the Mallory-Weiss syndrome
- A. gastric fundus
 - B. * cardial pert;
 - C. pyloric department;
 - D. from duodenal;
 - E. from a thick intestine
1415. Giant ulcer is an ulcer measuring
- A. over 4,5 cm
 - B. * over 3 cm
 - C. over 4 cm
 - D. over 5 cm
 - E. over 3,5 cm
1416. Hemobilia is
- A. * all answers are correct;
 - B. bleeding the bilious ways and liver;
 - C. bleeding the general bilious channel;
 - D. bloody clot in the big duodenal papilla;
 - E. all answers are not correct.
1417. Hernioplasty by Kimbarovsky is mean:
- A. Use of alloplastic material
 - B. Strengthening of lateral wall of inguinal channel
 - C. Narrowing of inguinal channel
 - D. Strengthening of posterior wall of inguinal channel
 - E. * Renewing the inguinal channel to it normal state
1418. Hernioplasty by Kukudzhanov is mean:
- A. Use of alloplastic material
 - B. Strengthening of lateral wall of inguinal channel
 - C. Narrowing of inguinal channel
 - D. Strengthening of anterior wall of inguinal channel
 - E. * Strengthening of posterior wall of inguinal channel
1419. Hernioplasty by Martinov is mean:
- A. Use of alloplastic material
 - B. Strengthening of lateral wall of inguinal channel
 - C. Narrowing of inguinal channel
 - D. Strengthening of posterior wall of inguinal channel
 - E. * Strengthening of anterior wall of inguinal channel

1420. Hernioplasty by Rudzhi is mean:
- A. Strengthening of lateral wall of inguinal channel
 - B. Narrowing of inguinal channel
 - C. Strengthening of anterior wall of inguinal channel
 - D. Strengthening of posterior wall of inguinal channel
 - E. * Closing of hernia gate from the side of femoral channel
1421. Hernioplasty by Zhirar is mean:
- A. Use of alloplastic material
 - B. Strengthening of lateral wall of inguinal channel
 - C. Narrowing of inguinal channel
 - D. Strengthening of posterior wall of inguinal channel
 - E. * Strengthening of anterior wall of inguinal channel
1422. How many days patients stays in hospital after hernioplasty:
- A. 17 days
 - B. 14 days
 - C. 12 days
 - D. 10 days
 - E. * 2-5 days
1423. If a bowel is jammed in a hernia sack, the diameter will increase in:
- A. None of the listed part
 - B. Remote loop of bowel
 - C. Loop in a hernia sack
 - D. Distal loop of bowel
 - E. * Proximal loop of bowel
1424. If after dissecting of incarceration ring there are signs of necrosis of bowel, surgeon must:
- A. To perform the resection of bowel in the distance 50 cm
 - B. To perform the resection of bowel in the distance 60 cm
 - C. To perform the resection of bowel in the distance 70 cm
 - D. To replace a bowel in an abdominal cavity
 - E. * To perform the resection of bowel in the distance 25-30 cm proximally and 10-15 cm distally
1425. If during introduction of finger to the superficial ring of inguinal channel the pulsation of lower epigastric artery is determined laterally to the hernia swelling, its mean:
- A. Incarcerated inguinal hernia
 - B. Femoral hernia
 - C. Umbilical hernia
 - D. Oblique inguinal hernia
 - E. * Direct inguinal hernia
1426. If during introduction of finger to the superficial ring of inguinal channel the pulsation of lower epigastric artery is determined medially to the hernia swelling, its mean:
- A. Incarcerated inguinal hernia
 - B. Umbilical hernia
 - C. Direct inguinal hernia
 - D. Femoral hernia
 - E. * Oblique inguinal hernia
1427. If hernia, complicated by phlegmon, is jammed:

- A. Performed hernioplasty by Kukudzhanov
 - B. Performed hernioplasty by Spasokukocky
 - C. Performed hernioplasty by Sapezhko
 - D. Performed hernioplasty by Bassini
 - E. * A hernioplasty is not performed
1428. If in a hernia sack organs compressed with lost of function, necrosis, its mean:
- A. Damage of hernia
 - B. Tumor of hernia
 - C. Nonreducible hernia
 - D. Inflammation of hernia
 - E. * Incarceration of hernia
1429. In case of incarceration of loop of bowel, above the hernia sack will be:
- A. Absence of sounds
 - B. Clang
 - C. Sonorous sound
 - D. Dull sound
 - E. * Tympanit
1430. In the case of direct inguinal hernia lower epigastric vessels are located:
- A. Behind a hernia sack
 - B. Higher hernia sack
 - C. Medially from a hernia sack
 - D. Below hernia sack
 - E. * Lateral to hernia sack
1431. In the case of incarceration of omentum above the hernia sack will be:
- A. Absence of sounds
 - B. Clang
 - C. Sonorous sound
 - D. Tympanit
 - E. * Dull sound
1432. In the case of negative cough sign will be:
- A. Tumor of hernia
 - B. Inflammation of hernia
 - C. Coprostasis
 - D. Nonreducible hernia
 - E. * Incarceration of hernia
1433. In the case of oblique inguinal hernia lower epigastric vessels are located:
- A. Behind a hernia sack
 - B. Lateral to hernia sack
 - C. Higher hernia sack
 - D. Below hernia sack
 - E. * Medially from a hernia sack
1434. In the case of the incarcerated hernia a main symptom is:
- A. Nausea and vomit
 - B. Bleeding
 - C. Negative cough sign
 - D. High temperature
 - E. * Pain in the hernia swelling

1435. In what area of stomach practically never is not origin of ulcers, or it is extraordinarily rarely?
- A. small curvature of stomach;
 - B. back wall of stomach, nearer to small curvature;
 - C. large curvature of stomach
 - D. * cardiac part of stomach;
 - E. pylorus.
1436. In what vein is a venous outflow carried out in from a stomach?
- A. * V. Portae;
 - B. V. odd;
 - C. V. pair;
 - D. V. overhead hollow;
 - E. V. lower hollow;
1437. Incarcerated hernia does not complicated by:
- A. Acute ileus
 - B. Peritonitis
 - C. Necrosis of hernia sack
 - D. Phlegmon of hernia sack
 - E. * Lymphadenitis
1438. Incarcerated hernia must be treated:
- A. Conservative treatment
 - B. Dynamic supervision
 - C. By reducing of hernia
 - D. Planned operation
 - E. * Urgent operation
1439. Large ulcer is an ulcer measuring
- A. 1-4 cm
 - B. 1-3 cm
 - C. 3-5 cm
 - D. 2- 6 cm
 - E. * 2-3 cm
1440. Little ulcer it is an ulcer measuring
- A. * to 0,5 cm
 - B. 0,5-1 cm
 - C. to 1,0 cm
 - D. 3 to 1,5 cm
 - E. 0,5-1,5 cm
1441. Lower epigastric vessels at oblique inguinal hernia is located:
- A. Behind hernia sack
 - B. Laterally to hernia sack
 - C. Higher to hernia sack
 - D. Below to hernia sack
 - E. * Medially to hernia sack
1442. Maydlya hernia is:
- A. Unreducible hernia
 - B. Incarceration of sliding hernia

- C. Incarceration of diverticulum of Meckel
 - D. Wall incarceration
 - E. * Retrograde incarceration
1443. Measure of resection of the incarcerated bowel:
- A. 10-15 cm distally
 - B. 25-30 cm proximally
 - C. Within the limits of visible healthy tissue
 - D. 15-20 cm proximally and 5-10 cm distally
 - E. * 25-30 cm proximally and 10-15 cm distally
1444. Meets the most frequent localization bleeding the digestive tract is
- A. gullet;
 - B. stomach;
 - C. rectum;
 - D. * duodenum;
 - E. colon
1445. Melena is
- A. black designed chair
 - B. * black liquid tarry chair
 - C. a discoloured liquid excrement
 - D. foamy stinking emptying of black
 - E. an excrement designed veined blood
1446. Melena is a characteristic sign
- A. * bleeding ulcer
 - B. for cicatrical-ulcerous pylorus stenosis
 - C. perforated ulcers
 - D. penetration ulcers
 - E. malignization ulcers
1447. Method of examination of incarcerated hernia is:
- A. Colonoscopy
 - B. Endoscopy
 - C. CT
 - D. Sonography
 - E. * X-Ray examination
1448. Methods of operative treatment of the left-side oblique reducible inguinal hernia:
- A. Methods of Sapezhko, Meye
 - B. Methods of Abrazhanov, Caravanov
 - C. Methods of Rudzhi, Parlavecho, Praksin
 - D. Methods of Bassini, Kukudzhinov, Postempsky
 - E. * Methods of Martinov, Zhirar-Spasokukocky-Kimbarovsky
1449. Most frequent form of incarceration:
- A. All listed meets rare
 - B. All listed meets often
 - C. Incarceration is mixed
 - D. Excrement incarceration
 - E. * Elastic incarceration
1450. Most informing method at a bleeding ulcer

- A. survey sciagraphy the organs of abdominal region
 - B. * EFGDS
 - C. sciagraphy the stomach with contrasting
 - D. Sonography
 - E. Laparoscopy
1451. Name classic complications of ulcerous illness
- A. bleeding, pylorostenosis, second pancreatitis, malignization, perforation
 - B. * perforation, penetration, bleeding, pylorostenosis, malignization
 - C. malignization, pylorostenosis, penetration, anaemia, perforation
 - D. bleeding, perforation, second pancreatitis, anaemia, malignization
 - E. perforation, peritonitis, pancreatitis, bleeding, penetration
1452. Negative cough sign means:
- A. Tumor of hernia
 - B. Inflammation of hernia
 - C. Coprostasis
 - D. Nonreducible hernia
 - E. * Incarceration of hernia
1453. Nonreducible hernia arises because of:
- A. Necrosis
 - B. Coprostasis
 - C. Peristalsis
 - D. An acute jamming of hernia content in the hernia gate
 - E. * Adhesion process between hernia content and hernia sack
1454. Objective sign of the incarcerated hernia:
- A. Bleeding
 - B. Positive cough sign
 - C. Vomit
 - D. Pain
 - E. * Negative cough sign
1455. On the method of the plastic by Bassini is performed:
- A. Strengthening of medial wall of inguinal channel
 - B. Suturing of defect of anterior abdominal wall
 - C. Strengthening of lateral wall of inguinal channel
 - D. Strengthening of anterior wall of inguinal channel
 - E. * Creation or strengthening of posterior wall of inguinal channel
1456. Opening, through which goes out direct inguinal hernia:
- A. White line of abdomen
 - B. Femoral channel
 - C. Lateral inguinal fossa
 - D. Left inguinal fossa
 - E. * Medial inguinal fossa
1457. Operating access at operations on a stomach
- A. * Upper-middle laparotomy
 - B. Lower-middle laparotomy
 - C. Pararectum access
 - D. Volokovich-Dyakonov's access
 - E. Pfannenstiel's access

1458. Operation which narrow inguinal channel without its opening:
- A. Method of Spasokukotsky, Kimbarovsky
 - B. Method of Bassini, Kukudzhanov
 - C. Method of Ru
 - D. Method of Martinov, Zhirar
 - E. * Method of Postempsky
1459. Operation, which is used at right nonreducible femoral hernia:
- A. Methods of Martinov, Postempsky
 - B. Methods of Bassini, Kukudzhanov, Postempsky
 - C. Methods of Martinov, Jirar, Spasokukocky, Kimbarovsky
 - D. Methods of Sapezhko, Meyo
 - E. * Methods of Bassini, Rudzhi, Parlavecho
1460. Operations of narrowing of inguinal channel without it opening is named by:
- A. By Spasokukotsky, Kimbarovsky
 - B. By Bassini, Kukudzhanov
 - C. By Martinov, Zhirar
 - D. By Postempsky
 - E. * By Cherni, Ru
1461. Operations of renewing of inguinal channel is named by:
- A. Method of Lockwood
 - B. Method of Kirschner
 - C. Method of Postempsky
 - D. Method of Cherni, Ru
 - E. * Method of Martinov, Zhirar
1462. Operations with liquidation of inguinal channel is named by:
- A. Method of Lockwood
 - B. Method of Kirschner
 - C. Method of Cherni, Ru
 - D. Method of Martinov, Zhirar
 - E. * Method of Postempsky
1463. Patient which the gastroenteric bleeding in house is necessary
- A. * To send a patient in surgical permanent establishment
 - B. To appoint rest, enter Cacl, vicasol
 - C. To wash a stomach, appoint a cold, rest of supervision
 - D. To send a patient in a therapeutic gastroenterology separation
 - E. A right answer absents
1464. Principle of Janov method is:
- A. Strengthening of upper wall of inguinal channel
 - B. Strengthening of anterior wall of inguinal channel
 - C. Strengthening of lateral wall of inguinal channel
 - D. Strengthening of posterior wall of inguinal channel
 - E. * Use for hernioplasty patch of skin
1465. Principle of Kirschner method is:
- A. Strengthening of upper wall of inguinal channel
 - B. Strengthening of anterior wall of inguinal channel
 - C. Strengthening of lateral wall of inguinal channel

- D. Strengthening of posterior wall of inguinal channel
 - E. * Used for hernioplasty of wide femoral fascia
1466. Principle of Lexer method at umbilical hernia is:
- A. Vertical cut on middle line
 - B. Removing of the umbilicus
 - C. Horizontal hernioplasty
 - D. Transversal hernioplasty
 - E. * Placing of circle sutures around the edges of defect
1467. Principle of Lockwood method is:
- A. Strengthening of upper wall of inguinal channel
 - B. Strengthening of anterior wall of inguinal channel
 - C. Strengthening of lateral wall of inguinal channel
 - D. Strengthening of posterior wall of inguinal channel
 - E. * Closing of femoral channel by sewing inguinal ligament to the periosteum of pubic bone
1468. Principle of Zhirar method is:
- A. Use of alloplastic material
 - B. Strengthening of lateral wall of inguinal channel
 - C. Narrowing of inguinal channel without its opening
 - D. Strengthening of posterior wall of inguinal channel
 - E. * Strengthening of anterior wall of inguinal channel
1469. Principles of Meyo method:
- A. Strengthening of posterior wall of inguinal channel
 - B. Strengthening of anterior wall of inguinal channel
 - C. Strengthening of lateral wall of inguinal channel
 - D. Formation of double-layer of white line
 - E. * Suturing of defect of anterior abdominal wall in the area of umbilical ring by U-shape sutures
1470. Purpose of the using of Kukudzhanov method:
- A. Closing of hernia gate is from the side of femoral channel
 - B. Strengthening of lateral wall of inguinal channel
 - C. Narrowing of inguinal channel is without its opening
 - D. Strengthening of anterior wall of inguinal channel
 - E. * Strengthening of posterior wall of inguinal channel
1471. Radical operation at a bleeding gastric ulcer and duodenum consists in
- A. sewing vessels on a draught;
 - B. * vagotomy or resection the stomach;
 - C. sewing vessels in an ulcer;
 - D. gastroenteroanastomosis;
 - E. all answers are faithful
1472. Relative absolute indication to operative treatment ulcerous illness is
- A. * penetration of ulcer
 - B. ulcerous anamnesis more than 15 years
 - C. malignization ulcers
 - D. perforation of ulcer
 - E. relapses more than 3 times per a year

1473. Resection of stomach by Bilrot II belongs to
- A. * radical operation
 - B. palliative operation
 - C. draining operations
 - D. organ protect operation
 - E. does not belong to any group
1474. Selective proximal vagotomy belongs to
- A. palliative
 - B. draining
 - C. * organ protect operation
 - D. resection
 - E. does not belong to any group
1475. Signs of non-complicated hernia are all, except:
- A. Nausea
 - B. Constipation
 - C. Swelling
 - D. Vomit
 - E. * Bleeding from hernia
1476. Signs of stable hemostasis
- A. * absence blood in a stomach and duodenum bulb;
 - B. presence the light blood and faltungs of blood in a stomach;
 - C. profluvium blood from a vessel;
 - D. all answers correct;
 - E. all answers are not correct
1477. Signs of unstable hemostasis
- A. * the pulsation of vessel is determined;
 - B. the bottom ulcer is covered a fibrin;
 - C. profluvium blood from a vessel;
 - D. all answers are correct;
 - E. all answers are not correct.
1478. Strengthening of posterior wall of inguinal channel performed at the hernioplasty by:
- A. Martinov
 - B. Kimbarovsky
 - C. Rudzhi
 - D. Meyo
 - E. * Bassini
1479. Swelling in the area of lateral fossa is means:
- A. Umbilical hernia
 - B. Epigastroceles
 - C. Direct inguinal hernia
 - D. Femoral hernia
 - E. * Oblique inguinal hernia
1480. Swelling in the area of medial fossa is means:
- A. Umbilical hernia
 - B. Epigastroceles
 - C. Oblique inguinal hernia
 - D. Femoral hernia

- E. * Direct inguinal hernia
1481. Swelling of anterior abdominal wall in the area of lateral fossa could be at:
- A. Direct and oblique inguinal hernia
 - B. Epigastroceles
 - C. Direct inguinal hernia
 - D. Femoral hernia
 - E. * Oblique inguinal hernia
1482. Swelling of anterior abdominal wall in the area of medial fossa could be at:
- A. Direct and oblique inguinal hernia
 - B. Epigastroceles
 - C. Femoral hernia
 - D. Oblique inguinal hernia
 - E. * Direct inguinal hernia
1483. Tactic of doctor, if during hospitalization incarcerated hernia is replaced:
- A. Nothing to do
 - B. Conservative treatment
 - C. To discharge patient
 - D. Urgent surgical treatment
 - E. * Hospitalization, supervision
1484. Tactic of surgeon during replacing of the incarcerated hernia during operation:
- A. Finishing of operation
 - B. Draining of abdominal cavity
 - C. Laparotomy
 - D. Hernioplasty without revision of nearest organs
 - E. * Operative treatment with the revision of nearest organs
1485. The „symptom of flowing” is characteristic for:
- A. Epigastroceles
 - B. Umbilical hernia
 - C. Inguinal hernia
 - D. Femoral hernia
 - E. * Diaphragmatic hernia
1486. The anterior wall of inguinal channel is:
- A. Inguinal ligament
 - B. Lower edge of internal oblique and transversal muscles of abdomen
 - C. Direct muscle of abdomen
 - D. Transversal fascia
 - E. * Aponeurosis of external oblique muscle of abdomen
1487. The best method for differential diagnostics of acute hydroxy of testicle with the incarcerated inguinal hernia is:
- A. Colonoscopy
 - B. Endoscopy
 - C. CT
 - D. Sonography
 - E. * Diaphanoscopy
1488. The effective method of prophylaxis of incarceration of hernia is:
- A. Changing of job

- B. Diet
 - C. Anti-spastic drugs
 - D. Antibiotics
 - E. * The planned operations
1489. The elastic incarceration develops:
- A. Languidly
 - B. With high speed
 - C. Too slowly
 - D. Gradually
 - E. * Suddenly
1490. The excrement incarceration arises up at:
- A. Sneeze
 - B. Cough
 - C. Physical training
 - D. Bleeding
 - E. * Decreasing of peristalsis
1491. The excrement incarceration develops:
- A. Too slowly
 - B. Suddenly
 - C. With high speed
 - D. Languidly
 - E. * Gradually
1492. The external wall of femoral channel is:
- A. Transversal fascia
 - B. Os pubis
 - C. Lakunar ligament
 - D. Inguinal ligament
 - E. * Femoral vein
1493. The internal wall of femoral channel is formed by:
- A. Transversal fascia of abdomen
 - B. By the inguinal ligament
 - C. By a femoral vein
 - D. By the horizontal branch of pubic bone
 - E. * By the edge of Jimbernat ligament
1494. The lower wall of inguinal channel is formed by:
- A. Pubic bone
 - B. Transversal fascia of abdomen
 - C. Aponeurosis of external oblique muscle of abdomen
 - D. Lower edge of internal oblique and transversal muscles of abdomen
 - E. * Inguinal ligament
1495. The method of Kukudzhanov is performed at hernioplasty of:
- A. Umbilical hernia
 - B. Femoral and inguinal hernia
 - C. Epigastroceles
 - D. Femoral hernia
 - E. * Inguinal hernia

1496. The method of Spasokukotsky is performed at hernioplasty of:
- A. Umbilical hernia
 - B. Umbilical hernia
 - C. Femoral hernia
 - D. Direct inguinal hernia
 - E. * Oblique inguinal hernia
1497. The methods of hernioplasty with using of synthetic materials:
- A. Fixation of graft for the edges of defect
 - B. Fixation of graft between peritoneum and aponeurosis layer (inlay technic)
 - C. Fixation of graft under autoplasty (sublay technic)
 - D. Fixation of graft above autoplasty (onlay technic)
 - E. * All listed methods
1498. The nosotropic mechanisms bleedingness at ulcerous illness is
- A. * all answers are correct.
 - B. permanent hyperemia all system of stomach
 - C. different degree dystrophy of superficial layers the mucus shell
 - D. accumulation the central mucopolysaccharides
 - E. hypoplastic, dystrophic processes
1499. The objective sign of hernia is:
- A. Vomit
 - B. Nausea
 - C. Constipation
 - D. Pain
 - E. * Swelling
1500. The posterior wall of femoral channel is:
- A. Transversal fascia of abdomen
 - B. Edge of Jimbernat ligament
 - C. Femoral vein
 - D. Inguinal ligament
 - E. * Horizontal branch of pubic bone
1501. The posterior wall of inguinal channel is:
- A. Pubic bone
 - B. Inguinal ligament
 - C. Lower edge of internal oblique and transversal muscles of abdomen
 - D. Aponeurosis of external oblique muscle of abdomen
 - E. * Transversal fascia of abdomen
1502. The resection of the loop of incarcerated bowel in hernia gate is indicated:
- A. At presence of all of the listed signs
 - B. In default of pulsation of mesentery vessels
 - C. In default of discoloration
 - D. In default of peristalsis
 - E. * At presence of any of the listed signs
1503. The retrograde incarceration arises up at presence of:
- A. Adhesion in a hernia sack
 - B. Wrong form of hernia gate
 - C. Narrow hernia gate
 - D. Negative pressure in a hernia sack

- E. * Wide hernia gate
1504. The retrograde incarceration looks like :
- A. Letters of F
 - B. Letters of R
 - C. Letters of B
 - D. Letters of G
 - E. * Letters of W
1505. The Richter incarceration arises up, when in a hernia sack located:
- A. Part of urinary bladder
 - B. Loop of bowel
 - C. Lateral wall of bowel
 - D. Part of mesentery
 - E. * Part of wall of bowel
1506. The Rudzhi method is use for:
- A. Oblique and direct inguinal hernia
 - B. Direct inguinal hernia
 - C. Acquired oblique inguinal hernia
 - D. Congenital oblique inguinal hernia
 - E. * Femoral hernia
1507. The second stage of operation at incarcerated hernia:
- A. Sequence of manipulations not important
 - B. Section of hernia sack
 - C. Fixing of jammed organ
 - D. Puncture of hernia sack
 - E. * Scission of incarceration ring
1508. The secretory function stomach is carried out the next membrane of stomach
- A. * mucous membrane
 - B. internal muscular layer
 - C. serosal
 - D. mucous submembrane
 - E. external layer
1509. The signs of non-complicated hernia are all, except of:
- A. Nausea
 - B. Constipation
 - C. Swelling
 - D. Vomit
 - E. * Bleeding from hernia
1510. The sizes of hernia gate at small hernia:
- A. Over 20 cm
 - B. Over 15 cm
 - C. To 15 cm
 - D. To 8 cm
 - E. * To 2 cm
1511. The upper wall of inguinal channel is:
- A. Pubic bone
 - B. Transversal fascia of abdomen

- C. Inguinal ligament
 - D. Aponeurosis of external oblique muscle of abdomen
 - E. * Lower edge of internal oblique and transversal muscles of abdomen
1512. To absolute indication to operative interference at ulcerous illness does not belong
- A. * scarry-ulcerous stenosis
 - B. perforation of ulcer
 - C. profuse bleeding
 - D. diameter ulcer a more than 3 cm
 - E. bleeding what does not stopped with conservative
1513. To the gastric – intestinal bleeding of un ulcerous etiology belong
- A. * Mallory-Weiss syndrome;
 - B. hemorrhagic erosive gastritis;
 - C. diseases by Randyu – Oslera – Vebera;
 - D. Menetrie's sing;
 - E. all answers are correct.
1514. Udin's sing at a perforated ulcer is
- A. * feeling at palpation shove the gases which penetrate through the perforated opening
 - B. dulling perforated sound in the lateral departments of stomach
 - C. disappearance of hepatic dullness
 - D. irradiation pain in a shoulder or shoulder-blade
 - E. sickliness the back vault of vagina
1515. Vomiting coffee-grounds is a characteristic sign
- A. * bleeding ulcer
 - B. penetrative ulcers
 - C. perforated ulcers
 - D. malignizated ulcers
 - E. for cicatrical-ulcerous pylorus stenosis
1516. Vomiting what arose up in 4-6 hours after eating characteristic for
- A. chronic alcoholic gastritis
 - B. cancer and ulcers of cardia
 - C. * pylorus ulcers
 - D. achalasia of gullet
 - E. ulcer and cancer the body of stomach
1517. Wall of inguinal channel, which is strengthened at the plastic by Bassini:
- A. Anterior and posterior
 - B. Lower
 - C. Upper
 - D. Anterior
 - E. * Posterior
1518. What additional symptom, which will arise up at incarceration of sliding inguinal hernia, the wall of which is an urinary bladder:
- A. Absence of other symptoms
 - B. Bleeding
 - C. Symptom of sexual weakness
 - D. Intoxication symptom
 - E. * Disuria

1519. What colouring of chair is most characteristic for bleeding from the ulcer of stomach and duodenum?
- A. * Tarry excrement
 - B. Presence on the formed excrement of strokes of red blood
 - C. Littlechanged blood in an excrement
 - D. Excrement of the raspberry colouring with the admixtures of mucus
 - E. Acholic excrement
1520. What complication the ulcerous illness of stomach is most characteristically for the patients of elderly and senile age
- A. perforation
 - B. perforation + bleeding
 - C. pylorus stenosis
 - D. malignization + penetration
 - E. * bleeding
1521. What complications can be at incarceration of omentum:
- A. Peritonitis
 - B. Necrosis of hernia sack
 - C. Intestinal obstruction
 - D. Phlegmon of hernia sack
 - E. * A thrombosis of vessels of omentum and embolism of portal vein
1522. What diameter of hernia gate at large hernia:
- A. Over 8 cm
 - B. Over 14 cm
 - C. Over 12 cm
 - D. Over 10 cm
 - E. * Over 4 cm
1523. What diameter of hernia gate at middle hernia:
- A. Over 8 cm
 - B. Over 14 cm
 - C. Over 12 cm
 - D. Over 10 cm
 - E. * Up to 4 cm
1524. What does form the anterior wall of femoral channel?
- A. Transversal fascia
 - B. Pubic bone
 - C. Lakunar ligament
 - D. Femoral vein
 - E. * Inguinal ligament
1525. What external signs are characteristic for the profuse bleeding from a gastric ulcer?
- A. Vomiting by the littlechanged blood, excrement of the raspberry colouring
 - B. * Vomiting by the littlechanged blood, tarry darkly-cherry chair
 - C. Vomiting by a complete mouth by dark blood with clots, black formed excrement
 - D. Vomiting on the type of "coffee-grounds", presence on the formed incandescence of strokes of red blood
 - E. Tarry darkly-cherry chair
1526. What from preparations has the expressed bacteriostatic action on Helicobacter pyloris
- A. * trichopol

- B. Liciviroton
 - C. oxiferiskorbon
 - D. atropine
 - E. pirinzsipin
1527. What from the transferred operations does not belong to organ protective
- A. trunk vagotomy
 - B. * resection by Bilrot II
 - C. selective vagotomy
 - D. selective proximal vagotomy
 - E. the all transferred does not belong
1528. What from the transferred operations on the stomach organ protective is
- A. * selective proximal vagotomy
 - B. resection by Bilrot I
 - C. resection by Bilrot II
 - D. gastrectomy
 - E. all are transferred
1529. What hernia has mesoperitoneal organ as part of hernia sack wall:
- A. Umbilical hernia
 - B. Oblique inguinal hernia
 - C. Femoral hernia
 - D. Direct inguinal hernia
 - E. * Sliding hernia
1530. What hernia is operated by Sapezhko method?
- A. Direct inguinal hernia
 - B. Only at hernia of white line
 - C. Only umbilical hernia
 - D. Only femoral hernia
 - E. * Umbilical and white line
1531. What hernia tissue can be the tumors origin?
- A. Never arise
 - B. Hernia sack
 - C. Membrane of hernia
 - D. Hernia content
 - E. * All listed elements of hernia
1532. What hernioplasty is indicated in case of phlegmon of hernia sack:
- A. Meyo hernioplasty
 - B. Bassini hernioplasty
 - C. Hernioplasty with draining of wound
 - D. Performed by any methods
 - E. * Contra-indicated
1533. What hormones undertake the protective operating on the mucous membrane of stomach, except for
- A. * ACTH
 - B. epidermal factor of growth
 - C. prostaglandin E
 - D. estrogens
 - E. STH

1534. What is contra-indicated for patients with coprostitis?
A. Enemas
B. Antispastic
C. Anaesthetic
D. Easy local massage
E. * Purgative drugs
1535. What is external hernia of abdomen:
A. An output of organs through the damaged abdominal wall
B. Jamming of organs
C. Inflammations of organs
D. An output of organs outside of peritoneum
E. * Output of organs, covered by peritoneum under a skin
1536. What is incarcerated hernia:
A. Jamming of content of hernia is from the side of abdominal cavity
B. Inflammation of hernia
C. Jamming of content of hernia by the wall of hernia sack
D. Jamming of content of hernia by surrounding tissue
E. * A jamming of content of hernia in its gate
1537. What is initial femoral hernia?
A. Swelling goes out outside of internal femoral ring
B. Swelling goes out outside superficial fascia
C. Swelling passes all anatomic structure of femoral channel
D. Swelling does not go outside superficial fascia
E. * Swelling does not go outside of internal femoral ring
1538. What is internal hernia of abdomen:
A. An output of organs through the damaged abdominal wall
B. Jamming of organs
C. Inflammations of organs
D. An output of organs outside of peritoneum
E. * The output of organs through the natural folds of peritoneum within the limits of abdominal cavity
1539. What is Lihtenshtein method?
A. Hernioplasty with painter net
B. Hernioplasty with metallic net
C. Hernioplasty with arachnoidite net
D. Hernioplasty with polyethylene net
E. * Hernioplasty with mesh material "Ethicon"
1540. What is Littre hernia ?
A. Nonreducible hernia
B. Incarceration of sliding hernia
C. Antegrade incarceration
D. Retrograde incarceration
E. * Incarceration of Mekkel diverticul
1541. What is more frequent forms wall at sliding left-side inguinal hernia?
A. Stomach
B. Transverse colon

- C. Urinary bladder
 - D. Small intestine
 - E. * Sigmoid colon
1542. What is more frequent forms wall at sliding right-side inguinal hernia?:
- A. Stomach
 - B. Transverse colon
 - C. Urinary bladder
 - D. Small intestine
 - E. * Urinary bladder
1543. What is not characteristic for determination of viability of incarcerated bowel:
- A. Presence of peristalsis
 - B. Presence of pulsation of mesentery vessels
 - C. Absence of strangulation furrow
 - D. Renewing of the natural color of organ
 - E. * Presence of strangulation furrow
1544. What is orifice of hernia sack?
- A. Its widest part
 - B. Its upper part
 - C. Its lower part
 - D. Distal part of hernia sack
 - E. * Part of hernia sack, which connected with abdominal cavity
1545. What is principle of Lexer method at umbilical hernia?
- A. Vertical cut on middle line
 - B. Removing of the umbilicus
 - C. Horizontal hernioplasty
 - D. Transversal hernioplasty
 - E. * Placing of circle sutures around the edges of defect
1546. What is Richter's hernia?
- A. Nonreducible hernia
 - B. Incarceration of sliding hernia
 - C. Incarceration of diverticulum of Meckel
 - D. Retrograde incarceration
 - E. * A hernia in which only a portion of the wall of the intestine is involved.
1547. What is the condition of expression and character of development of pathological changes at incarceration hernia?:
- A. Degree of jamming of organ by the incarcerated ring
 - B. Structure of jammed organ
 - C. State of vessels
 - D. Duration of incarceration
 - E. * All listed signs
1548. What is the first sign of the false incarceration?
- A. Intestinal obstruction
 - B. Peritonitis
 - C. Intoxication syndrome
 - D. Pain in the hernia
 - E. * Pain in the abdominal cavity

1549. What is the first step of operation at the incarcerated hernia?
- A. Estimation of viability of jammed organ
 - B. Conservative treatment
 - C. Dissecting of jamming ring
 - D. Puncture of hernia sack.
 - E. * Quick opening of hernia sack and fixing of jammed organ.
1550. What is the internal wall of femoral channel?:
- A. Transversal fascia of abdomen
 - B. Inguinal ligament
 - C. Femoral vein
 - D. Horizontal branch of pubic bone
 - E. * Edge of Jimbernat ligament
1551. What is the most frequent complication of incarcerated hernia:
- A. Colitis
 - B. Tumor of colon
 - C. Pancreatitis
 - D. Peptic ulcer
 - E. * Necrosis of hernia sack
1552. What is the principle of inlay technic of the hernioplasty of postoperative hernia:
- A. All are transferred methods
 - B. Fixation of graft for the edges of defect
 - C. Fixation of graft above autoplasty
 - D. Fixation of graft under autoplasty
 - E. * Fixation of graft between peritoneum and aponeurosis layer
1553. What is the principle of onlay technic of the hernioplasty of postoperative hernia:
- A. All are transferred methods
 - B. Fixation of graft for the edges of defect
 - C. Fixation of graft between peritoneum and aponeurosis layer
 - D. Fixation of graft under autoplasty
 - E. * Fixation of graft above autoplasty
1554. What is the principle of sublay technic of the hernioplasty of postoperative hernia:
- A. All are transferred methods
 - B. Fixation of graft for the edges of defect
 - C. Fixation of graft between peritoneum and aponeurosis layer
 - D. Fixation of graft above autoplasty
 - E. * Fixation of graft under autoplasty
1555. What is the superior wall of inguinal channel?
- A. Pubic bone
 - B. Transversal fascia of abdomen
 - C. Inguinal ligament
 - D. Aponeurosis of external oblique muscle of abdomen
 - E. * Lower edge of internal oblique and transversal muscles of abdomen
1556. What is the time of disability after treatment of incarcerated hernia?:
- A. 14 days
 - B. 1 week
 - C. 4-6 days
 - D. 12 weeks

- E. * 4-6 weeks
1557. What localization of ulcer is most characteristic for the patients of elderly and senile age
- * cardial department of stomach
 - overhead third of gullet
 - lower third of gullet
 - bulb of duodenum
 - small curvature
1558. What method diagnostics the ulcerous illness most informing
- * esophagogastroduodenoscopy
 - analysis of excrement on the hidden blood
 - X-ray
 - global analysis of blood
 - research of gastric secretion
1559. What method is it orientation possible to define the volume of hemorrhage on at the acute gastroenteric bleeding?
- On maintenance red corpuscles, haemoglobin, Ht, thrombocytes
 - On blood volume
 - * On an arteriotomy, pulse, state of patient
 - On a globular volume
 - On the level of thrombocytes
1560. What method is used for closing of hernia gate from the side of femoral channel:
- Method of Spasokukotsky
 - Method of Meyo
 - Method Caravanov
 - Methods of Lockwood and Abrazhanov
 - * Method of Rudzhi
1561. What methods of hernioplasty at postoperative hernia?:
- Aponeurotic hernioplasty
 - Alloplasty by a tantal mesh
 - Alloplasty by lavsan suture
 - Muscle-aponeurotic
 - * All listed
1562. What name of method of closing of femoral channel by sewing of inguinal ligament to the periosteum of pubic bone?
- Method Caravanov
 - Method of Spasokukotsky
 - Method of Meyo
 - Method of Rudzhi
 - * Method of Lockwood
1563. What name of the symptoms of the incarcerated hernia:
- Nausea and vomit
 - Pain in the hernia swelling
 - Negative cough sign
 - Nonreducible swelling
 - * All are transferred signs
1564. What preparation does behave to blocker H2-retseptors?

- A. * tavegil
 - B. obzidan
 - C. hystdol
 - D. cerucal
 - E. oraza
1565. What preparation does behave to blocker of muscarine receptors of coating cages?
- A. cymetidin
 - B. eglonin
 - C. * gastocepini
 - D. etimsiloli
 - E. vinylin
1566. What preparations, except for other properties, own yet and a bacteriostatic effect on *Helicobacter pylori*
- A. * all are transferred preparations
 - B. Almagel
 - C. Vinylin
 - D. De-nol
 - E. Claritromycin
1567. What products are recommended in the diet of № 1?
- A. * hen in a steam kind
 - B. pancakes
 - C. raw egg-white
 - D. bread rye fresh
 - E. acute cheeses
1568. What signs of viability of the jammed loop of bowel is used?:
- A. By a tint
 - B. By a color
 - C. By the presence of pulsation of vessels
 - D. By the presence of peristalsis
 - E. * Used all signs
1569. What stages has by medial vascular-lacunar femoral hernia?
- A. Incomplete, complete
 - B. Initial, complete
 - C. Incomplete, complete, eventual
 - D. First, second, third
 - E. * Initial, incomplete, complete
1570. What syndrome is characteristic for hemorrhagic erosive gastritis?
- A. * ulcerous
 - B. hemorrhagic;
 - C. pain;
 - D. all answers are correct;
 - E. all answers are not correct.
1571. What time urgent operations are executed at acute bleeding
- A. * 6 – 12 hours;
 - B. 6 – 10 hours;
 - C. 6 – 8 hours
 - D. 6 – 14 hours;

- E. 6 – 20 hours
1572. What violation of mineral exchange is characteristic for patients with ulcerous illness of stomach and intestine
- A. hypocalcemia
 - B. * hypokaliemia
 - C. Hyponatremia
 - D. Hypercalcinemia
 - E. hyperkaliemia
1573. What wall of inguinal channel is strengthened by Bassini hernioplasty:
- A. Anterior and posterior
 - B. Inferior
 - C. Superior
 - D. Anterior
 - E. * Posterior
1574. What wall of inguinal channel is strengthened at the plastic by Kukudzhanov:
- A. Anterior and posterior
 - B. Inferior
 - C. Superior
 - D. Anterior
 - E. * Posterior
1575. When apply Teylor's method at ulcerous illness
- A. * at conservative treatment perforated ulcers
 - B. at conservative treatment sanguifluous ulcers
 - C. at conservative treatment penetration ulcers
 - D. at conservative treatment malignization ulcers
 - E. at conservative treatment of cicatrical pylorostenosis
1576. When could be false incarceration of hernia?
- A. At incarceration of diverticul of Meckel
 - B. At inflammation of hernia
 - C. At jamming of the organ in a hernia sack
 - D. At the partial incarceration of wall of organ
 - E. * At the acute diseases of organs of abdominal cavity
1577. When lower epigastric vessels is located laterally to hernia sack?
- A. Epigastroceles
 - B. Umbilical hernia
 - C. Oblique inguinal hernia
 - D. Femoral hernia
 - E. * Direct inguinal hernia
1578. When lower epigastric vessels is located medially to hernia sack?
- A. Epigastroceles
 - B. Umbilical hernia
 - C. Direct inguinal hernia
 - D. Femoral hernia
 - E. * Oblique inguinal hernia
1579. With the purpose of strengthening of anterior wall of inguinal channel it is performed:
- A. Method of Kirschner

- B. Method of Postempsky
 - C. Method of Bassini, Kukudzhanov
 - D. Method of Ru
 - E. * Methods of Martinov, Zhirar, Spasokukotsky
1580. A patient 40 years old, suffered ulcerous diseases of stomach. Last 2 days the pain became less intensive, but weakness and dizziness were appeared. Rose from a bed and lost consciousness. Pale. There are insignificant pains in epigastrium. It is
- A. Combination perforation with bleeding
 - B. Perforation
 - C. Malignization of ulcer
 - D. Stenosis of ulcer
 - E. * Gastroenteric bleeding
1581. A patient, 32 years, 4 hours ago has "knife-like" abdominal pain. Diagnosis?
- A. Acute appendicitis.
 - B. Acute ileus.
 - C. Acute pancreatitis.
 - D. Gangrenous cholecystitis.
 - E. * All of answers are incorrect.
1582. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. * malignization ulcers
 - C. ulcerous anamnesis more than 10 years
 - D. heavy pain syndrome, proof heartburn
 - E. relapse ulcer after vagotomy
1583. Absolute sign of unstable hemostasis
- A. * profluvium blood from a vessel;
 - B. absence blood in a stomach and bulb of duodenum;
 - C. presence light blood and faltungs of blood in a stomach;
 - D. all answers are correct;
 - E. all answers are not correct
1584. After what operation at ulcerous illness the natural arcade of meal is saved on a digestive tract
- A. Valter-Braun's gastroenterostomy
 - B. not saved after any operation
 - C. resection by Bilrot II
 - D. * resection by Bil'rot I
 - E. saved after all transferred operations
1585. After what operation innervation of pyloric department of stomach is saved
- A. * selective vagotomy
 - B. barrel vagotomy
 - C. selective proximal vagotomy
 - D. at all transferred
 - E. not saved after all operations
1586. Among the symptoms of perforative peptic ulcer one is indicated wrong:
- A. Positive symptom of Schetkin-Blumberg.
 - B. Disappearance of hepatic sound.
 - C. There is a knife-like pain.

- D. Tension of muscles of anterior abdominal wall.
 - E. * Vomiting is not facilitate.
1587. An absolute indication to the operation at peptic ulcerous disease are:
- A. Persistent duodeno-gastric reflux with gastritis and peptic ulcer
 - B. Presence of genetic predisposition to peptic ulcerous disease
 - C. Combination of gigant gastric and duodenal peptic ulcers
 - D. Large peptic ulcer of pylorus with possible development of stenosis
 - E. * Penetrative peptic ulcer with formation of pathological fistula
1588. An intraduodenal brake effect of acid secretion is realized through:
- A. Duodeno-gastric reflux
 - B. Decreasing of pancreatic secretion
 - C. Increasing of pancreatic secretion
 - D. Increasing of bile production
 - E. * Increasing of secretine production
1589. An operation at a duodenal peptic ulcer is not performed at:
- A. Development of malignancy
 - B. Development of perforation
 - C. Development of stenosis
 - D. Massive bleeding
 - E. * Formation of peptic ulcer after anti-inflammation non-steroid drug
1590. Appearance of disgust for meat is the most characteristic complaint of patient with:
- A. Peptic peptic ulcer
 - B. Pancreatitis
 - C. peptic ulcerous disease of stomach
 - D. Uremic gastritis
 - E. * Cancer of stomach
1591. At a large gastric peptic ulcer the best method of treatment is:
- A. Selective proximal vagotomy.
 - B. Gastrectomy.
 - C. Selective vagotomy and pyloroplasty by Finney.
 - D. Trunk vagotomy with excision of peptic ulcer.
 - E. * Resection of stomach.
1592. At beginning bleeding from an ulcer
- A. * pain diminishes
 - B. pain increases
 - C. there is knife-like pain
 - D. character of pain does not change
 - E. girdle pain
1593. At bleeding emergency operative interferences are executed
- A. * to 3 hours
 - B. to 1,5 hour
 - C. to 6 hours
 - D. to 8 hours
 - E. 6 – 12 hours
1594. At determination of indications to surgical treatment of peptic ulcerous disease not important:

- A. Duration of disease
 - B. Duration of remission
 - C. Efficiency of conservative therapy
 - D. Frequency of relapses
 - E. * Expressed of inflammation in region of pylorus and duodenum
1595. At determination of indications to the operation of peptic ulcerous disease there it is important:
- A. Sizes of antral part of stomach
 - B. Secretion
 - C. Evacuation function of stomach and duodenum
 - D. X-Ray examination of stomach and duodenum
 - E. * Information of endoscopic examination of peptic ulcer and its localization
1596. At determination of indications to the operation of peptic ulcerous disease there it is not important:
- A. Duodeno-gastric reflux
 - B. Gastric secretion
 - C. Pathogenesis of disease
 - D. Complications of peptic ulcerous disease
 - E. * Predisposition to dumping-syndrome
1597. At III stage blood loss at the bleeding ulcer the patient loses
- A. more than 25 % blood volume
 - B. * more than 30 % blood volume
 - C. more than 20 % blood volume
 - D. more than 15 % blood volume
 - E. more than 35 % blood volume
1598. At often relapse of peptic ulcers of duodenum it is possible to suspect:
- A. Bleeding
 - B. Perforation
 - C. Penetration
 - D. Tumor
 - E. * Syndrome of Zollinger-Ellison.
1599. At patient 40 years old 5 hours ago the perforation of gastric peptic ulcer is happened. What is the best surgical treatment:
- A. Gastrectomy.
 - B. Vagotomy and pyloroplasty.
 - C. Vagotomy and sewing of peptic ulcer.
 - D. Antrumectomy.
 - E. * Classic resection 2/3 stomach.
1600. At patients with peptic ulcerous disease the risk of the gastro-duodenal bleeding is most high at:
- A. All of cases
 - B. Malignancy
 - C. Perforations of peptic ulcer
 - D. Stenosis of pylorus
 - E. * Penetration of peptic ulcer to the omentum
1601. At peptic ulcerous disease of stomach more frequent in all:
- A. Gastritis is expressed less than at a duodenal peptic ulcer.

- B. Malignity more rare, than at a duodenal peptic ulcer.
 - C. low pH in antral part
 - D. The motor function of stomach is enhanceable in an interdigestive period
 - E. * Surgical treatment is used considerably more frequent, than at a duodenal peptic ulcer.
1602. At peptic ulcerous disease:
- A. All of answers are faithful
 - B. Increased motility of duodenum
 - C. Considerably more frequent, than at a gastric peptic ulcer, surgical treatment is used
 - D. Decreased motility of duodenum
 - E. * Considerably more frequent, than at a gastric peptic ulcer, conservative treatment is used
1603. At perforative gastric peptic ulcer method of operation is determined from:
- A. Age of patient
 - B. Time from the moment of perforation
 - C. Degree of peritonitis
 - D. Localization of the perforation
 - E. * All of listed
1604. At suspicion of duodenal peptic ulcer is performed:
- A. Examination of gastric secretion
 - B. X-Ray of organs of abdominal cavity
 - C. Cholecystography
 - D. Determination of level of gastrin in blood
 - E. * Esophagogastroduodenoscopy
1605. At suspicion on the perforative peptic ulcer of stomach the first examination must be:
- A. Laparoscopy
 - B. Angiography
 - C. Urgent esophagogastroduodenoscopy
 - D. X-Ray of stomach with barium
 - E. * X-Ray of abdominal region
1606. At the duodenum ulceroperation of choice is
- A. * resection by Bilrot I
 - B. resection by Bilrot II
 - C. resection of duodenum
 - D. selective proximal vagotomy
 - E. sewing up of ulcer
1607. At the gastroenteric bleeding the middle degree of blood loss is diagnosed at next indexes
- A. Hb below 80 g/l
 - B. * Hb 80-100 g/l
 - C. red corpuscles below $2,5 \cdot 10^{12}/l$
 - D. red corpuscles of $3,5-4,0 \cdot 10^{12}/l$
 - E. Ht below 25%
1608. At the III item of activity hemostasis and III sage blood loss from the I – III sage blood loss indicated
- A. * urgent operations (6 – 12 hours);
 - B. emergency operations (to 3 hours);
 - C. exigent operations (12 – 24 hours);

- D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
1609. At the relapse of the peptic ulcerous gastro-duodenal bleeding is performed:
- A. Conservative therapy
 - B. Colonoscopy
 - C. Sonography
 - D. Planned surgical treatment
 - E. * Urgent operation
1610. At the threat of relapse of the peptic ulcerous gastro-duodenal bleeding is recommended:
- A. Conservative therapy
 - B. Colonoscopy
 - C. Sonography
 - D. Planned surgical treatment
 - E. * Urgent operation
1611. At the V item activity of hemostasis and at the recurrent bleeding of the I – III item of blood loss indicated
- A. * emergency operations (to 3 hours);
 - B. urgent operations (6 – 12 hours);
 - C. exigent (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
1612. At ulcerous illness can a bleeding source be
- A. artery;
 - B. veins;
 - C. shallow vessels and ulcers;
 - D. all answers are not correct.
 - E. * all answers are correct
1613. At which disease will be tension of muscles of anterior abdominal wall?
- A. At pylorostenosis
 - B. At hernia
 - C. At appendicitis
 - D. At chronic gastritis
 - E. * Right answer not present
1614. Belching by bright red blood which increased at a cough is characteristic for:
- A. Syndrome of Randyu - Osler
 - B. Bleeding gastric peptic ulcer
 - C. Syndrome of Mellori - Weiss
 - D. Tumor of cardiac part
 - E. * Pulmonary bleeding
1615. Bergman's sign is characteristic for
- A. * bleeding ulcer
 - B. for cicatrical-ulcerous pylorostenosis
 - C. perforated ulcers
 - D. penetration ulcers
 - E. malignization ulcers
1616. Berhstein's sign characteristic for

- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorostenosis
1617. Bleeding ulcer, complicated blood loss III stage degrees, requires
- A. * blood and its components transfusions
 - B. transfusion of salt solutions
 - C. transfusion of colloid solutions
 - D. transfusion of salt and colloid solutions
 - E. infusion therapy does not need
1618. Blood loss I stage characterized such indexes
- A. Ht 48-44, Hb 120
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 31-23, Hb 80
 - D. * Ht 38-32, Hb 100
 - E. Ht 44-40, Hb 110 /?
1619. Blood loss II stage characterized
- A. * Ht 23 and below, Hb 50 and below
 - B. Ht 31-23, Hb 80
 - C. Ht 44-40, Hb 110
 - D. Ht 48-44, Hb 120
 - E. Ht 48-44, Hb 120
1620. Blood loss III stage characterized a degree such indexes
- A. * Ht 31-23, Hb 80
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 38-32, Hb 100
 - D. Ht 44-40, Hb 110
 - E. Ht 48-44, Hb 120
1621. By the most credible reason of development peptic ulcer by decreasing of resistance of mucous tunic of stomach is:
- A. Hormonal changes in organism
 - B. Deficit of plastic and biochemically active substances
 - C. Local ischemia of gastro-duodenal mucous membrane
 - D. Metabolic changes in organism
 - E. * Chronic gastritis
1622. Choice of method of operative treatment at the perforative peptic ulcer complicated by peritonitis?
- A. Selective proximal vagotomy
 - B. Pyloroplasty with vagotomy
 - C. Antrumectomy with vagotomy
 - D. Subtotal resection of stomach
 - E. * Sewing of the perforative opening
1623. Clinical sign of perforative peptic ulcer in the first 6 hours of disease is not characterized by:
- A. By absence of vomiting.
 - B. By disappearance of hepatic sound.

- C. By a "knife-like" abdominal pain.
 - D. Wooden belly.
 - E. * Diarrhea.
1624. Conservative therapy at perforative peptic ulcer is prescribed only at:
- A. Combination of peptic ulcerous disease of stomach and duodenum
 - B. High degree of operating risk
 - C. Absence in patient peptic ulcerous anamnesis
 - D. Old age of patients
 - E. * Absence of possibility of urgent operation
1625. De-Cerven's sign is characteristic for
- A. bleeding ulcer
 - B. * perforated ulcers
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorostenosis
1626. Decreasing of gastric acid secretion comes at duodenal pH:
- A. 6,0
 - B. 3,0
 - C. 4,0
 - D. 5,0
 - E. * 2,5 and below
1627. Decreasing of pain and appearance of "melena" at duodenal peptic ulcer is characteristic for:
- A. Penetration to pancreas
 - B. Pyloroduodenal stenosis
 - C. Malignancy
 - D. Perforations of peptic ulcer
 - E. * Bleeding
1628. Diet at bleeding gastric and duodenum ulcers
- A. * Meulengracht's
 - B. 1 by Pevznerom
 - C. 5 by Pevznerom
 - D. 15 by Pevznerom
 - E. 7 by Pevznerom
1629. Disappearance or diminishing the pain with beginning of bleeding from an ulcer is
- A. * Bergman's sign
 - B. Spazarskiy's sign
 - C. Mendel's sign
 - D. De Keven's sign
 - E. Eleker's sign
1630. Duration the period of primary shock at a perforated ulcer
- A. * 3-6 hours
 - B. 6-12 hours
 - C. 1-3 hours
 - D. 12-24 hours
 - E. 24-36 hours

1631. During transformation of gastric peptic ulcer to cancer will be such clinical signs: 1. Decreasing of pain. 2. Appearance of anemia. 3. Change of appetite. 4. Absent of "niche" at X-Ray examination of stomach. Choose correct combination of answers:
- 1 and 3.
 - Only 4.
 - 2,3.
 - 1,2,3.
 - * 1,2,3,4.
1632. Eleker's sign is characteristic for
- * perforated ulcers
 - bleeding ulcer
 - penetrated ulcers
 - malignized ulcers
 - for cicatricial-ulcerous pylorostenosis
1633. Endoscopic examination does not diagnose:
- Stenosis of pylorus
 - Type of gastritis
 - Cancer of stomach
 - Syndrome of Mellori - Weiss
 - * Syndrome of Zollinger - Ellison
1634. Endoscopy does not allow:
- To perform pH- metry
 - To inform about cardiac sphincter and pylorus
 - To inform about mucous membrane of gullet, stomach and duodenum
 - To inform about peptic ulcerous defect and define its localization
 - * To define the degree of duodenogastric reflux
1635. Esophagogastroduodenoscopy can find out next changes in a stomach, except for
- tumours
 - ulcers
 - bleeding polypuses
 - erosions
 - * changes of evacuation function
1636. Etiopatogenetic method of operation at the uncomplicated duodenal peptic ulcer is:
- Selective vagotomy
 - trunk vagotomy
 - combination of antrumectomy with trunk vagotomy
 - ideal antrumectomy with trunk vagotomy
 - * SPV (selective proximal vagotomy)
1637. For bleeding ulcer characteristic sign is
- * pain in an epigastrium;
 - knife-like pain;
 - signs irritation of peritoneum;
 - presence fresh blood in incandescence
 - melena;
1638. For bleeding ulcer characteristically
- * melena
 - tension the muscles of front abdominal wall

- C. Spazarskiy's sign
 - D. sickliness the back vault of vagina
 - E. irradiation pain in a shoulder or shoulder-blade
1639. For chronic gastro-duodenal peptic ulcers is not characteristic:
- A. Possibility of develop different complications
 - B. Dense edges
 - C. Different sizes of peptic ulcerous defect
 - D. Penetration
 - E. * Absence of convergence of folds of mucous membrane
1640. For decompensated stenosis of pylorus is characteristic: 1. Vomiting by food which eaten the day before. 2. Tension of muscles of abdominal wall. 3. Decrease of diuresis. 4. "Splash sound" in abdomen on an empty stomach. 5. Delay of barium in a stomach more than 24 hours. Choose correct combination of answers:
- A. 1,2.
 - B. 1,2,3,4.
 - C. 1,2,4,5.
 - D. 1,2,4.
 - E. * 1,3,4,5.
1641. For decompensated stenosis of pylorus is not characteristic:
- A. Delay of barium in a stomach more than 24 hours on X-Ray
 - B. Vomiting by food, eaten a day before
 - C. Oliguria
 - D. Splash sound" in a abdomen on an empty stomach
 - E. * Tension of muscles of abdominal wall
1642. For decompensated stenosis of pylorus is not characteristic:
- A. Delay of barium in stomach for more than 24 hours
 - B. Splash sound in empty stomach
 - C. Anuria
 - D. Vomiting by food, eaten the day before
 - E. * Tension of muscles of abdominal wall
1643. For motion of disease ulcerous illness of middle weight characteristically
- A. development of complications
 - B. * relapses 1-2 times per a year
 - C. 4 and anymore relapses on a year
 - D. 5 and more relapses are on a year
 - E. 3 and anymore relapses on a year
1644. For perforative gastric peptic ulcer in the first 6 hours is not characteristic:
- A. Gas under the diaphragm
 - B. Acute stomach
 - C. Absent of hepatic sound
 - D. Wooden belly
 - E. * Swelling of stomach
1645. For perforative gastro-duodenal peptic ulcer is characteristic:
- A. General weakness
 - B. Vomiting
 - C. Spastic pain
 - D. Gradual growth of pain syndrome

- E. * Acute pain in epigastrium
1646. For perforated ulcer characteristically
- A. * tension the muscles of front abdominal wall
 - B. melena
 - C. vomiting by coffee-grounds
 - D. high intestinal impassability
 - E. vomiting stagnant gastric maintenance
1647. For pneumoperitoneum is characteristic symptom
- A. * Zhober's;
 - B. Khelatid's;
 - C. Podlag's;
 - D. Vigats's;
 - E. Udin's.
1648. For successful surgical treatment of duodenal peptic ulcer is necessarily:
- A. Sonography
 - B. Angiography
 - C. Examination of liver
 - D. Colonoscopy
 - E. * Estimation of the state of pylorus
1649. For successful surgical treatment of duodenal peptic ulcer not necessarily:
- A. Examination of duodenal permeability
 - B. Determination of gastrin production
 - C. Estimation of the state of pylorus
 - D. Examination of gastric secretion
 - E. * Determination of etiology of peptic ulcer
1650. For the bleeding peptic ulcer not characteristic:
- A. Decreasing of blood volume
 - B. Melena
 - C. Decreasing of hemoglobin
 - D. Vomiting by color of coffee-grounds
 - E. * Increasing of pain in stomach
1651. For the bleeding peptic ulcer the followings signs are characteristic: 1. There is increasing of pain syndrome. 2. Vomiting by "coffee-grounds". 3. There is decreasing pain syndrome. 4. Bradicardia. 5. Melena. Choose correct combination of answers:
- A. 1,3,5.
 - B. 3,4,5.
 - C. 2,3,4.
 - D. 1,2,5.
 - E. * 2,3,5.
1652. For the heavy flow of ulcerous illness characteristically
- A. 2 and anymore relapses on a year
 - B. * 3 and anymore relapses on a year
 - C. 4 and anymore relapses on a year
 - D. 5 and more relapses are on a year
 - E. 6 and more relapses are on a year
1653. For the heavy flow of ulcerous illness characteristically

- A. * development of complications
 - B. seasonal exacerbation more not frequent 1-2 times per a year
 - C. 1-2 relapse on a year
 - D. liquid, but protracted exacerbation
 - E. exacerbation duration more than 10 days
1654. For what complications of peptic ulcer is characteristic convergences of folds of mucous membrane:
- A. Bleeding
 - B. Stenosis
 - C. Perforation
 - D. Penetration
 - E. * Malignancy
1655. From what department digestive tract development more frequent than all the bleeding at the Mallory-Weiss syndrome
- A. gastric fundus
 - B. * cardial part;
 - C. pyloric department;
 - D. from duodenal;
 - E. from a thick intestine
1656. Giant ulcer is an ulcer measuring
- A. over 4,5 cm
 - B. * over 3 cm
 - C. over 4 cm
 - D. over 5 cm
 - E. over 3,5 cm
1657. Hemobilia is
- A. * all answers are correct;
 - B. bleeding the bilious ways and liver;
 - C. bleeding the general bilious channel;
 - D. bloody clot in the big duodenal papilla;
 - E. all answers are not correct.
1658. How to explain the reason of appearance of tension of muscles in the right iliac region in patients with perforative peptic ulcer:
- A. Viscero-visceral reflex.
 - B. Developing of peritonitis.
 - C. Reflex through the spinal nerves.
 - D. An accumulation of air in abdominal region.
 - E. * Flowing of gastric content to the right lateral channel
1659. How to find the source of the gastro-duodenal bleeding:
- A. Sonography
 - B. X-Ray examination of stomach
 - C. Nasogastric probe
 - D. Laparoscopy
 - E. * Endoscopy
1660. If patient with perforative gastric peptic ulcer is refuse from the operation, it is prescribed:
1. Cleaning the stomach by cold water.
 2. Long-term naso-gastric aspiration.
 3. Stimulation of

intestine. 4. Antibiotic therapy. 5. Position of Trendelenburg. Choose correct combination of answers:

- A. 2,3,5.
- B. 1,2,5.
- C. 1,4.
- D. 2,3,4,5.
- E. * 2,4.

1661. In what area of stomach practically never is not origin of ulcers, or it is extraordinarily rarely?

- A. small curvature of stomach;
- B. back wall of stomach, nearer to small curvature;
- C. large curvature of stomach
- D. * cardiac part of stomach;
- E. pylorus.

1662. In what vein is a venous outflow carried out in from a stomach?

- A. * V. Portae;
- B. V. odd;
- C. V. pair;
- D. V. overhead hollow;
- E. V. lower hollow;

1663. Indications to surgical treatment of the uncomplicated peptic ulcerous disease are: 1. Low localization of peptic ulcer. 2. Long time of peptic ulcerous anamnesis with the frequent relapse. 3. Young age of patient. 4. Ineffective conservative treatment more than 3 months. Choose correct combination of answer.

- A. 1,2,3,4.
- B. 1,4.
- C. 2,3,4.
- D. 1,3.
- E. * 2,4.

1664. Isolated selective proximal vagotomy is performed at:

- A. Gastro-duodenal bleeding.
- B. Malignancy.
- C. Perforative peptic ulcer
- D. Duodenal peptic ulcer with subcompensated stenosis of pylorus.
- E. * Duodenal chronic peptic ulcer without the stenosis.

1665. Large ulcer is an ulcer measuring

- A. 1-4 cm
- B. 1-3 cm
- C. 3-5 cm
- D. 2- 6 cm
- E. * 2-3 cm

1666. Little ulcer it is an ulcer measuring

- A. * to 0,5 cm
- B. 0,5-1 cm
- C. to 1,0 cm
- D. 3 to 1,5 cm
- E. 0,5-1,5 cm

1667. Maximal Histamin test at peptic ulcerous disease is used for:
- A. Estimations of efficiency of H-2 blockers.
 - B. Determinations of base acid production.
 - C. Determinations of function of antrum part of stomach.
 - D. Examinations of motility of stomach.
 - E. * Examinations of humoral phase of gastric secretion.
1668. Meets the most frequent localization bleeding the digestive tract is
- A. gullet;
 - B. stomach;
 - C. rectum;
 - D. * duodenum;
 - E. colon
1669. Melena is
- A. black designed chair
 - B. * black liquid tarry chair
 - C. a discoloured liquid excrement
 - D. foamy stinking emptying of black
 - E. an excrement designed veined blood
1670. Melena is a characteristic sign
- A. * bleeding ulcer
 - B. for cicatrical-ulcerous pylorus stenosis
 - C. perforated ulcers
 - D. penetration ulcers
 - E. malignization ulcers
1671. Most informing method at a bleeding ulcer
- A. survey sciagraphy the organs of abdominal region
 - B. * EFGDS
 - C. sciagraphy the stomach with contrasting
 - D. Sonography
 - E. Laparoskopy
1672. Most physiological method of resection of stomach:
- A. Resection by Raykhel-Polia
 - B. Bilioth-II in modification by Hakker-Balfur
 - C. Bilioth-II in modification by Hofmeister-Finsterer
 - D. Resection in modification by Ru
 - E. * Bilrot-I
1673. Name class complications of ulcerous illness
- A. bleeding, pyloristhenosis, second pancreatitis, malignization, perforation
 - B. * perforation, penetration, bleeding, pyloristhenosis, malignization
 - C. malignization, pyloristhenosis, penetration, anaemia, perforation
 - D. bleeding, perforation, second pancreatitis, anaemia, malignization
 - E. perforation, peritonitis, pancreatitis, bleeding, penetration
1674. Name the most characteristic symptom of chronic gastric peptic ulcer:
- A. Weakness
 - B. Pain in 1,5-2 hours after food intake
 - C. Heartburn
 - D. Vomiting

- E. * Pain in 30 minutes after food intake
1675. Name the most characteristic symptom of chronic peptic ulcer:
- A. Vomiting
 - B. Pain in 2,5-3 hours after food intake
 - C. Pain in 30 minutes after food intake
 - D. Nightly pain
 - E. * Heartburn, pain in 1,5-2 hours after food intake
1676. Name the most informative method of examination at dumping-syndrome:
- A. Colonoscopy
 - B. Examination of volume of circulatory blood
 - C. Endoscopy
 - D. CT
 - E. * X-Ray with barium
1677. Operating access at operations on a stomach
- A. * Upper-middle laparotomy
 - B. Lower-middle laparotomy
 - C. Pararectum access
 - D. Volokovich-Dyakonov's access
 - E. Pfanenhtil's access
1678. Operation of choice at peptic ulcerous disease with violation of duodenal passage is:
- A. SPV without the special correction of the duodenal passage
 - B. SPV with duodeno-jejuno anastomosis
 - C. Resection of stomach (antrumectomy) with vagotomy by Gofmeyster-Finsterer
 - D. Resection of stomach (antrumectomy) with vagotomy by Bilroth-1
 - E. * Resection of stomach (antrumectomy) with vagotomy by Ru
1679. Operative treatment of patient with a duodenal peptic ulcer is performed in cases of: 1. There are often relapses of disease, 2. A disease is complicated by bleeding, 3. A disease is complicated by stenosis 4. A disease is complicated by perforation of peptic ulcer 5. A disease is complicated by penetration. Choose correct combination of answers:
- A. 1,2
 - B. 3,4
 - C. 2,3
 - D. 1,4
 - E. * 1,2,3,4,5.
1680. Patient which the gastroenteric bleeding in house is necessary
- A. * To send a patient in surgical permanent establishment
 - B. To appoint rest, enter Cacl, vicasol
 - C. To wash a stomach, appoint a cold, rest of supervision
 - D. To send a patient in a therapeutic gastroenterology separation
 - E. A right answer absents
1681. Patients with the compensated pyloroduodenal stenosis without the signs of active peptic ulcer:
- A. Operated after 2-monthly course of intensive antipeptic ulcer therapy
 - B. Does not need surgical treatment
 - C. Operated only in the case of progress of stenosis
 - D. Need surgical treatment in the case of intensifying of peptic ulcerous disease
 - E. * Need obligatory surgical treatment

1682. Penetrative gastric and duodenal peptic ulcer can result of: 1. abscess of abdominal region 2. pylephlebitis, 3. fistule 4. acute pancreatitis 5. bleeding. Choose correct combination of answers:
- A. 1,2,3,4,5
 - B. 1,3,5.
 - C. 1,2,3
 - D. 2,3,4.
 - E. * 3,4,5.
1683. Planning of operation on duodenal peptic ulcer, there it is not important:
- A. Examination of function of duodenum
 - B. X-Ray of stomach
 - C. Endoscopic examination of lung
 - D. Examine of gastric secretion
 - E. * Examination of secretion of pancreas
1684. Radical operation at a bleeding gastric ulcer and duodenum consists in
- A. sewing vessels on a draught;
 - B. * vagotomy or resection the stomach;
 - C. sewing vessels in an ulcer;
 - D. gastroenteroanastomosis;
 - E. all answers are faithful
1685. Rare complication of peptic ulcer is:
- A. Cicatricial deformation of bowel
 - B. Penetration
 - C. Bleeding
 - D. Perforation
 - E. * Malignancy
1686. Relative absolute indication to operative treatment ulcerous illness is
- A. * penetration of ulcer
 - B. ulcerous anamnesis more than 15 years
 - C. malignization ulcers
 - D. perforation of ulcer
 - E. relapses more than 3 times per a year
1687. Relative indications to surgical treatment of peptic ulcerous disease:
- A. Atypical perforation of peptic ulcer
 - B. Malignant regeneration of peptic ulcer
 - C. Stenosis of pylorus
 - D. Relapse of the peptic ulcerous bleeding after endoscopic hemostasis
 - E. * Low bulb peptic ulcers
1688. Resection of stomach by Bilrot II belongs to
- A. * radical operation
 - B. palliative operation
 - C. draining operations
 - D. organ protect operation
 - E. does not belong to any group
1689. Selective proximal vagotomy belongs to
- A. palliative

- B. draining
 - C. * organ protect operation
 - D. resection
 - E. does not belong to any group
1690. Selective proximal vagotomy is not indicated for:
- A. peptic ulcers with subcompensated stenosis
 - B. Duodenal peptic ulcer, complicated by bleeding
 - C. Uncomplicated duodenal peptic ulcer
 - D. Perforative peptic ulcer
 - E. * Gastric and duodenal peptic ulcer
1691. Signs of stable hemostasis
- A. * absence blood in a stomach and duodenum bulb;
 - B. presence the light blood and faltungs of blood in a stomach;
 - C. profluvium blood from a vessel;
 - D. all answers correct;
 - E. all answers are not correct
1692. Signs of unstable hemostasis
- A. * the pulsation of vessel is determined;
 - B. the bottom ulcer is covered a fibrin;
 - C. profluvium blood from a vessel;
 - D. all answers are correct;
 - E. all answers are not correct.
1693. Spastic pain in epigastric region could be at
- A. Ascitis
 - B. Acute ileus
 - C. Hypertension
 - D. Chronic bronchitis
 - E. * Peptic peptic ulcer
1694. Specify factors, which determine the choice of method of operation at the perforative peptic ulcer of stomach: 1. Presence of peritonitis. 2. Time from the moment of perforation of peptic ulcer. 3. Qualification of surgeon. 4. General state and age of patient. 5. Sizes of peptic ulcer. Choose correct combination of answers:
- A. All of answers are correct.
 - B. 1,2,3,5.
 - C. 1,2,4.
 - D. 1,3,4,5.
 - E. * 1,2,3,4.
1695. Specify physiopathology changes characteristic for decompensated stenosis of pylorus: 1. Hypervolemia. 2. Anaemia. 3. Metabolic alkalosis. 4. Hypovolemiya. 5. Acidosis. Choose correct combination of answers:
- A. 2,3,4.
 - B. 4,5.
 - C. 1,3.
 - D. 2,4.
 - E. * 3,4.
1696. Specify the most characteristic symptoms of peptic ulcerous stenosis of pylorus:
- A. Weakness

- B. Constipation, vomiting
 - C. Constipation
 - D. Vomiting
 - E. * Filling of weight in the epigastrium
1697. Specify the most informative method of examination at a peptic ulcer:
- A. Colonoscopy
 - B. CT
 - C. Determine the gastric secretion
 - D. Sonography
 - E. * Endoscopy
1698. Syndrome of Mellori-Veys is:
- A. hemorrhagic erosive gastroduodenitis
 - B. Varicosity of cardiac part, complicated by bleeding
 - C. Bleeding from mucous membrane.
 - D. Bleeding peptic ulcer from diverticulum of Meckel
 - E. * Fissure in a cardiac part of stomach with bleeding
1699. Syndrome of Zollinger-Ellison is?
- A. Hepatitis
 - B. Cholecystitis
 - C. Diabetes
 - D. Hyperthyroidism
 - E. * Tumor of pancreas
1700. Tension of muscles at right iliac region at the perforation of duodenal peptic ulcer is explained by:
- A. By viscerovisceral reflex
 - B. By development of peritonitis
 - C. Bleeding
 - D. Entering of air to abdominal cavity
 - E. * Flowing of gastric content to the right lateral channel
1701. The best method of diagnostics of perforative peptic ulcers is:
- A. X-Ray
 - B. Endoscopy
 - C. Laparocentesis
 - D. Sonography
 - E. * Laparoscopy
1702. The best method of examination of gastric secretion is:
- A. by using a cabbage juice
 - B. by using an insulin
 - C. by using a coffee
 - D. by using a food
 - E. * by using Histaminum
1703. The best method of intraoperative control after vagotomy:
- A. MRI
 - B. CT
 - C. Sonography
 - D. X-Ray
 - E. * Intra gastric ??-metry by the special ??-tube

1704. The characteristic clinical signs of cancer of cardiac part of stomach is:
- A. Pain in epigastrium
 - B. Belch
 - C. Weakness
 - D. Sense of weight in epigastrium
 - E. * Dysphagia
1705. The characteristic of X-Ray signs of malignancy of stomach is:
- A. Rigidity of wall of stomach
 - B. Strengthening of peristalsis
 - C. Defect of filling
 - D. Niche"
 - E. * Convergence of folds of mucous membrane of stomach
1706. The clinic of decompensated pyloroduodenal stenosis is characterized:
- A. By a "splash sound" on an empty stomach.
 - B. By the hypovolemia.
 - C. Delay of barium in a stomach to 24 hours.
 - D. By the decrease of mass of body.
 - E. * All of answers are correct.
1707. The compensated stage of piloroduodenal stenosis is characterized by: 1. "Splash sound" on an empty stomach. 2. Vomiting at mornings. 3. By the delay of barium in a stomach more than 12 hours. 4. By the hypovolemia. 5. General weakness. Choose correct combination of answers:
- A. 1,2,3.
 - B. All of answers are correct.
 - C. 1,4,5.
 - D. 1,3,4.
 - E. * All of answers are wrong.
1708. The diet of Meylengraft is based:
- A. All listed is not right
 - B. On mechanical defense of mucous membrane of stomach
 - C. On providing of high-calorie food
 - D. On suppression of secretion of gastric juice
 - E. * All of listed is right
1709. The dumping-syndrome conditioned:
- A. By dilatation of stomach
 - B. By psycho state of patients
 - C. By hormonal changes
 - D. By the result of intestinal hyperosmose
 - E. * By the genetically determined reaction of organism on food products
1710. The gastric secretion in healthy persons:
- A. Brake
 - B. Inert
 - C. Asthenic
 - D. Excitable
 - E. * Normal
1711. The high risk of the gastro-duodenal bleeding has patients with:
- A. In all of cases.

- B. Malignancy.
 - C. Perforation of peptic ulcer.
 - D. Stenosis of pylorus.
 - E. * Penetration of peptic ulcer to the omentum.
1712. The highest level of acidity is observed at peptic ulcer in:
- A. Cardiac part of stomach
 - B. Body of stomach
 - C. Bottom of stomach
 - D. Antral part
 - E. * Pyloric part
1713. The initial process of peptic ulcer formation is depended from:
- A. With decreasing of secretion of pancreas
 - B. With reverse diffusion of hydrogen ions
 - C. With violation of acid-neutralization function of duodenum
 - D. With decompensation of antral acid-neutralization function
 - E. * Balance between the factors of defence and aggression of gastro-duodenal region
1714. The morning vomiting by “acid” is characterized by?
- A. Hepatitis
 - B. Cholecystitis
 - C. Diabetes
 - D. Hyperthyroidism
 - E. * To peptic ulcerous disease
1715. The most frequent complication of penetrative gastric peptic ulcer is:
- A. Perforation
 - B. Development of stenosis of pylorus
 - C. formation of fistula
 - D. Malignancy
 - E. * Bleeding
1716. The most typical complication of peptic ulcer of posterior wall of duodenum is:
- A. Stenosis.
 - B. Malignancy.
 - C. Penetration to the head of pancreas.
 - D. Perforation.
 - E. * Bleeding.
1717. The nosotropic mechanisms bleedingness at ulcerous illness is
- A. * all answers are correct.
 - B. permanent hyperemia all system of stomach
 - C. different degree dystrophy of superficial layers the mucus shell
 - D. accumulation the central mucopolysaccharides
 - E. hypoplastic, dystrophic processes
1718. The operation of choice at the perforative peptic ulcer of stomach in the stage of festering peritonitis is:
- A. Antrumectomy
 - B. SPV with sewing of perforation
 - C. Resection of stomach
 - D. Excision of peptic ulcer with vagotomy and pyloroplasty
 - E. * Sewing of perforation

1719. The reliable X-Ray sign of perforation of gastro-duodenal peptic ulcer is:
- Absent of gas in the stomach
 - Kloyber's "cup"
 - Gas in the intestine
 - High location of diaphragm
 - * Presence of free gas in abdominal region
1720. The secretory function stomach is carried out the next membrane of stomach
- * mucous membrane
 - internal muscular layer
 - serosal
 - mucous submembrane
 - external layer
1721. The symptoms of perforative gastric peptic ulcer are: 1. "Knife-like" pain. 2. Wooden belly. 3. Frequent vomiting. 4. Disappearance of hepatic sound. 5. Arterial hypertension. Choose correct combination of answers:
- 1,5.
 - 4,5.
 - 2,3.
 - 1,3,4.
 - * 1,2,4.
1722. The typical ways of metastasis of tumor of antrum part on large curvature of stomach is:
- Lymphatic nodes of pancreas
 - Mesenteric
 - Spleen
 - Paraesophageal lymphatic nodes
 - * Liver
1723. To absolute indication to operative interference at ulcerous illness does not belong
- * scarry-ulcerous stenosis
 - perforation of ulcer
 - profuse bleeding
 - diameter ulcer a more than 3 cm
 - bleeding what does not stopped with conservative
1724. To the gastric – intestinal bleeding of un ulcerous etiology belong
- * Mallory-Weiss syndrome;
 - hemorrhagic erosive gastritis;
 - diseases by Randyu – Oslera – Vebera;
 - Menetrie's sing;
 - all answers are correct.
1725. Udin's sing at a perforated ulcer is
- * feeling at palpation shove the gases which penetrate through the perforated opening
 - dulling perforated sound in the lateral departments of stomach
 - disappearance of hepatic dullness
 - irradiation pain in a shoulder or shoulder-blade
 - sickliness the back vault of vagina
1726. Vomiting coffee-grounds is a characteristic sign
- * bleeding ulcer

- B. penetrative ulcers
 - C. perforated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorus stenosis
1727. Vomiting what arose up in 4-6 hours after eating characteristic for
- A. chronic alcoholic gastritis
 - B. cancer and ulcers of cardia
 - C. * pylorus ulcers
 - D. achalasia of gullet
 - E. ulcer and cancer the body of stomach
1728. What are indications to operative treatment of peptic ulcer disease. 1. Perforation. 2. Penetration. 3. Stenosis of pylorus. 4. Malignancy. 5. Gastro-duodenal bleeding. Correct will be:
- A. Only 1.
 - B. 1,4,5.
 - C. 1,3,5.
 - D. 1,5.
 - E. * 1,2,3,4,5.
1729. What are indications to urgent operative treatment of peptic ulcer disease. 1. Perforation. 2. Penetration. 3. Stenosis of pylorus. 4. Malignancy. 5. Gastro-duodenal bleeding. Correct will be:
- A. 1,2,3,4,5.
 - B. Only 1.
 - C. 1,4,5.
 - D. 1,3,5.
 - E. * 1,5.
1730. What are the normal indexes of Histaminum-stimulated pH of body and antral parts of stomach?
- A. body 5,0-7,0, antrum part of stomach 5-7
 - B. body 3,0-4,0, antrum part of stomach 4-5
 - C. body 8,9-10, antrum part of stomach 1,5-2,5
 - D. body 0,5-0,7, antrum part of stomach 1-2
 - E. * body 1,2-1,6, antrum part of stomach from 5 and higher
1731. What colouring of chair is most characteristic for bleeding from the ulcer of stomach and duodenum?
- A. * Tarry excrement
 - B. Presence on the formed excrement of strokes of red blood
 - C. Littlechanged blood in an excrement
 - D. Excrement of the raspberry colouring with the admixtures of mucus
 - E. Acholic excrement
1732. What complication of peptic ulcerous disease has disappearance of pain in an epigastrium and appearance characteristic melena?
- A. Penetration of peptic ulcer to the pancreas.
 - B. Malignancy of peptic ulcer.
 - C. Pyloroduodenal stenosis.
 - D. Perforation of peptic ulcer.
 - E. * Bleeding from an peptic ulcer.

1733. What complication of peptic ulcerous disease of stomach is characteristic tension of abdominal muscles ?
- Stenosis.
 - Bleeding .
 - Penetration of peptic ulcer in a pancreas.
 - Covered perforation.
 - * Perforation in a free abdominal cavity.
1734. What complication the ulcerous illness of stomach is most characteristically for the patients of elderly and senile age
- perforation
 - perforation + bleeding
 - pylorus stenosis
 - malignization + penetration
 - * bleeding
1735. What complications of peptic ulcer disease: 1 Penetration, 2 Perforation, 3 Stenosis, 4 Bleeding, 5 Malignancy
- 1,3.
 - 1,3,4.
 - 2,3,4.
 - 1,2,3,4.
 - * 1,2,3,4,5
1736. What examination is performed at suspicion on the perforation of peptic ulcer:
- Colonoscopy.
 - Laparoscopy.
 - Gastroduodenoscopy.
 - Sonography.
 - * X-Ray of abdominal cavity
1737. What external signs are characteristic for the profuse bleeding from a gastric ulcer?
- Vomiting by the littlechanged blood, excrement of the raspberry colouring
 - * Vomiting by the littlechanged blood, tarry darkly-cherry chair
 - Vomiting by a complete mouth by dark blood with clots, black formed excrement
 - Vomiting on the type of "coffee-grounds", presence on the formed incandescence of strokes of red blood
 - Tarry darkly-cherry chair
1738. What factors is stipulate for the state of patient with peptic ulcerous piloro-duodenal stenosis?
- Hypovolemia
 - Low temperature
 - Arterial hypertension
 - High temperature
 - * Hypovolemia
1739. What from preparations has the expressed bacteriostatic action on Helicobacter pyloris
- * trichopol
 - Licviroton
 - oxiferiskorbon
 - atropine
 - pirinzsipin

1740. What from the listed do not important at choice method of operative treatment at the cancer of stomach?
- A. Histological structure of tumor
 - B. Prevalence of tumor
 - C. Weight of patients
 - D. Age of patients
 - E. * Duration of disease
1741. What from the listed reasons is main in development of duodeno-gastric reflux?
- A. Tumor of stomach
 - B. peptic ulcerous disease
 - C. Stenosis of pylorus
 - D. Inflammation of bile ducts
 - E. * Violation of duodenal permeability
1742. What from the methods of hemostasis at gastro-duodenal bleeding is most effective?
- A. Transfusion of small doses of blood
 - B. Antispastic drugs
 - C. Antiinflammation drugs
 - D. Intravenous introduction of Vicasol
 - E. * Endoscopic coagulation of bleeding
1743. What from the transferred operations does not belong to organ protective
- A. trunk vagotomy
 - B. * resection by Bilrot II
 - C. selective vagotomy
 - D. selective proximal vagotomy
 - E. the all transferred does not belong
1744. What from the transferred operations on the stomach organ protective is
- A. * selective proximal vagotomy
 - B. resection by Bilrot I
 - C. resection by Bilrot II
 - D. gastrectomy
 - E. all are transferred
1745. What hormones undertake the protective operating on the mucous membrane of stomach, except for
- A. * ACTH
 - B. epidermal factor of growth
 - C. prostaglandin E
 - D. estrogens
 - E. STH
1746. What includes method of Teylor at treatment of perforative peptic ulcer: 1. Putting probe in a stomach, 2 Permanent aspiration of gastric content, 3 Antibiotic therapy, 4 Desintoxication therapy.
- A. 1,3.
 - B. 1,3,4.
 - C. 2,3,4.
 - D. 1,2,3,4.
 - E. * All listed

1747. What indicated at a gastric peptic ulcer, which diagnosed during X-Ray examination of stomach:
- Immediate operation - resection of stomach.
 - Protracted conservative treatment,
 - Periodically X-Ray control
 - Operative treatment
 - * Gastroscopy with biopsy and treatment depending on its result
1748. What is basic methods of diagnostics at suspicion of the perforative gastric peptic ulcer: 1. X-Ray of stomach with barium. 2. Survey X-Ray of abdominal region. 3. Gastroduodenoscopy. 4. Sonography of abdominal region. 5. Laparoscopy. Choose correct combination of answers:
- All answers are correct.
 - 1,3,5.
 - 1,3.
 - 2,3,4.
 - * 2,5.
1749. What is characteristic for compensated pyloroduodenal stenosis :
- Severe condition of patients
 - Permanent pain in epigastric region
 - Constipation
 - Frequent vomiting
 - "Hungry" pain in epigastric region
1750. What is criteria of adequate preoperative preparation at patient with decompensated peptic ulcerous stenosis of pylorus: 1. Level of diuresis. 2. Indexes of volume of circulatory blood. 3. Level of hematocrit. 4. Indexes of electrolytes of blood. Choose correct combination of answers:
- All of answers are wrong.
 - 3 and 4.
 - 2,3,4.
 - 2,4.
 - * All of answers are correct.
1751. What is important in pathogenesis of peptic ulcerous disease of stomach: 1. Decreasing of motility of stomach. 2. Duodeno-gastric reflux. 3. Pancreatitis. 4. Violation of protective properties of mucous membrane. 5. Peritonitis. Choose correct combination of answers.
- 1,2,3,4,5.
 - 1,3,4
 - 1,2,3.
 - 2,4,5.
 - * 1,2,4.
1752. What is indicated at bleeding peptic ulcer of body of stomach and small degree of operating risk:
- Excision of peptic ulcer
 - Sewing of bleeding peptic ulcer with a pyloroplasty and vagotomy
 - Excision of bleeding peptic ulcer with SPV
 - Excision of bleeding peptic ulcer with a pyloroplasty vagotomy
 - * Segmental resection of stomach with a bleeding peptic ulcer with omeprazole
1753. What is indicated for the patient with decompensated peptic ulcerous stenosis of pylorus and convulsive syndrome:
- All of answers are true.

- B. Gastroduodenostomy.
 - C. Urgent gastrostomy.
 - D. Urgent resection of stomach.
 - E. * Resection of stomach in the planned order after the correction of general state.
1754. What is most frequent vagotomy is used:
- A. Posterior trunk.
 - B. Anterior trunk
 - C. Selective
 - D. Trunk
 - E. * SPV
1755. What is normal indexes of stomach pH in a body and in the antrum part of stomach?
- A. body 0,3-0,5, antrum part of stomach 1,1-1,9
 - B. body 0,3-0,5, antrum part of stomach 1,1-1,9
 - C. body 4,0-5,0, antrum part of stomach 1,0-1,5
 - D. body 0,8-1,0, antrum part of stomach 1,5-2,5
 - E. * body 1,6-2,2, antrum part of stomach from 5 and higher
1756. What is not characteristic for perforative peptic ulcer:
- A. Knife-like pain
 - B. Disappearance of hepatic sound
 - C. General weakness
 - D. Wooden belly
 - E. * Spastic pain in abdomen
1757. What is not complication of peptic ulcerous disease:
- A. Pyloroduodenal stenosis.
 - B. Gastro-duodenal bleeding.
 - C. Perforation of peptic ulcer.
 - D. Penetration of peptic ulcer.
 - E. * Malignancy of peptic ulcer.
1758. What is not indication to the operation at a duodenal peptic ulcer:
- A. Penetration of peptic ulcer.
 - B. Failure of conservative therapy.
 - C. Stenosis of pylorus.
 - D. Bleeding from peptic ulcer.
 - E. * Localization of peptic ulcers in a bulb of duodenum.
1759. What is pain localization at peptic ulcer of small curvature of stomach?
- A. In back
 - B. In left inguinal region
 - C. Near a umbilicus
 - D. In right inguinal region
 - E. * In epigastrium
1760. What is phases of perforation: 1 shock, 2 peritonitis, 3 pain phase, 4 “imaginary prosperity”, 5 recovery.
- A. 2,4,5.
 - B. 3,1,5.
 - C. 3,2,5.
 - D. 1,2,3.
 - E. * 1,4,2.

1761. What is prescribed for patients with decompensated stenosis of pylorus before operation: 1. Blood transfusion. 2. Solutions of glucose. 3. Solutions of Ringer. 4. Introduction of ions of potassium. 5. Introduction of osmotic diuretics. Choose correct combination of answers?
- A. 3,4,5.
 - B. 1,3,4.
 - C. 1,2,3.
 - D. 1,4,5.
 - E. * 2,3,4.
1762. What is prescribed for the patient with gastro-duodenal bleeding: 1. Permanent aspiration of gastric content. 2. X-Ray of stomach. 3. Gastroduodenoscopy. 4. Laparoscopy. 5. Determination of hemoglobin. Choose correct combination of answers:
- A. 3,4,5.
 - B. 1,3,4,5
 - C. 3,4,5
 - D. 1,2,3,4
 - E. * 1,3,5
1763. What is the best method of surgical treatment of peptic ulcerous disease, complicated by subcompensated stenosis of pylorus:
- A. Subtotal resection of stomach with a large and small omentum.
 - B. Anterior gastroenterostomy.
 - C. Selective proximal vagotomy.
 - D. Gastroduodenoanastomosis.
 - E. * Selective proximal vagotomy in combination with a pyloroplasty by Finney.
1764. What is the best method of treatment of patient, 28 years, with a duodenal peptic ulcer, complicated by subcompensated piloro-duodenal stenosis:
- A. Posterior gastroenteroanastomosis.
 - B. Trunk vagotomy.
 - C. Subtotal resection of stomach.
 - D. Selective proximal vagotomy.
 - E. * Selective proximal vagotomy in combination with a draining operation.
1765. What is the most typical complication of peptic ulcer with penetration to the head of pancreas:
- A. Reflux.
 - B. Stenosis of cardiac part of stomach.
 - C. Malignancy.
 - D. Perforation.
 - E. * Acute pancreatitis.
1766. What is the reasons of formation of peptic peptic ulcers after resection of stomach:
- A. Acute ileus
 - B. Pancreatitis
 - C. Syndrome of Zollinger - Ellison
 - D. Economy resection of stomach
 - E. * Is not resected antrum part of stomach
1767. What is treatment of peptic peptic ulcer disease with cicatrices and deformation of duodenum
- A. Conservative treatment
 - B. Antibiotic.

- C. Antispastic
 - D. H-2 blockers
 - E. * Operative treatment.
1768. What is triad of Mondor: 1 peptic ulcerous anamnesis, 2 knife-like pain, 3 wooden belly, 4 local peritonitis, 5 the shock state of patient
- A. 2,3,4.
 - B. 1,4,5.
 - C. 2,3,5.
 - D. 1,3,5.
 - E. * 1,2,3.
1769. What is used for diagnostics of perforative peptic ulcers:
- A. X-Ray
 - B. Endoscopy
 - C. Laparocentesis
 - D. Sonography
 - E. * Laparoscopy
1770. What localization of ulcer is most characteristic for the patients of elderly and senile age
- A. * cardial department of stomach
 - B. overhead third of gullet
 - C. lower third of gullet
 - D. bulb of duodewnum
 - E. small curvature
1771. What method diagnostics hte ulcerous illness most informing
- A. * esophagogastroduodenoscopy
 - B. analysis of excrement on the hidden blood
 - C. X-ray
 - D. global analysis of blood
 - E. research of gastric secretion
1772. What method is it orientation possible to define the volume of hemorrhage on at the acute gastroenteric bleeding?
- A. On maintenance red corpuscles, haemoglobin, Ht, thrombocytes
 - B. On blood volume
 - C. * On an arteriotony, pulse, state of patient
 - D. On a globular volume
 - E. On the level of thrombocytes
1773. What operation is performed after the hour after the perforation of gastric peptic ulcer:
- A. Any of the listed operations
 - B. Vagotomy with a pyloroplasty
 - C. Closing of perforative peptic ulcer
 - D. Antrumectomy
 - E. * Classic resection of 2/3 stomach
1774. What operation is performed at decompensated stenosis of pylorus in old patients?
- A. Subtotal resection of stomach
 - B. Resection of stomach
 - C. Pyloroplasty with vagotomy
 - D. Antrumectomy with vagotomy
 - E. * Gastroenteroanastomosis

1775. What operation is performed for patient, 43 years, with bleeding peptic ulcer of antrum part of stomach:
- Gastrectomy.
 - Conservative treatment.
 - Proximal vagotomy.
 - Excision of peptic ulcer with trunk vagotomy.
 - * Resection of stomach.
1776. What operation is performed in patient with the peptic ulcer, penetrated to the pancreas:
- Pyloroplasty by Finney
 - Selective proximal vagotomy.
 - Vagotomy and draining operation.
 - Distal subtotal resection of stomach.
 - * Resection 2/3 stomach
1777. What preparation does behave to blocker H₂-retseptors?
- * tavegil
 - obzidan
 - hystdol
 - cerucal
 - oraza
1778. What preparation does behave to blocker of muscarine receptors of coating cages?
- cymetidin
 - eglonin
 - * gastocepini
 - etimsiloli
 - vinilin
1779. What preparations, except for other properties, own yet and a bacteriostatic effect on Helicobacter pyloris
- * all are transferred preparations
 - Almagel
 - Vinylin
 - De-nol
 - Clarithromycin
1780. What products are recommended in the diet of № 1?
- * hen in a steam kind
 - pancakes
 - raw egg-white
 - bread rye fresh
 - acute cheeses
1781. What special methods of examination need to be applied at differentiation of acute appendicitis with the covered perforative peptic ulcer? 1. Gastroduodenoscopy. 2. X-Ray. 3. Sonography of abdominal region. 4. Laparoscopy. 5. Sciagraphy of stomach with the sulfate of barium. Choose correct combination of answers:
- Only 2 and 5.
 - Only 2 and 4.
 - 1,2,3.
 - 2,3,5.
 - * 1,2,4.

1782. What syndrome is characteristic for hemorrhagic erosive gastritis?
- A. * ulcerous
 - B. hemorrhagic;
 - C. pain;
 - D. all answers are correct;
 - E. all answers are not correct.
1783. What time urgent operations are executed at acute bleeding
- A. * 6 – 12 hours;
 - B. 6 – 10 hours;
 - C. 6 – 8 hours
 - D. 6 – 14 hours;
 - E. 6 – 20 hours
1784. What treatment of peptic ulcer, complicated by non-stopped gastro-duodenal bleeding?
- A. Introduction of probe of Blekmora.
 - B. Embolization of gastric and gastro-duodenal arteries.
 - C. Operation at the relapse of bleeding.
 - D. Conservative treatment.
 - E. * Urgent operation.
1785. What treatment of the covered perforation of peptic ulcer:
- A. Laparoscopic draining of abdominal cavity.
 - B. Treatment by method of Teylor.
 - C. Operation in the case of ineffective conservative treatment.
 - D. Conservative treatment.
 - E. * Urgent operation.
1786. What treatment of the perforative peptic ulcer after 15 hours from perforation?
- A. Antrumectomy
 - B. Gastroenteroanastomosis.
 - C. Resection of stomach.
 - D. Vagotomy with a pyloroplasty by Finney.
 - E. * Sewing of perforation.
1787. What treatment of the perforative peptic ulcer of antrum part of stomach.
- A. Antrumectomy.
 - B. Sewing of peptic ulcer and trunk vagotomy.
 - C. Resection 3/4 stomach with a large and small omentum.
 - D. Sewing of peptic ulcer.
 - E. * Resection of 2/3 stomach.
1788. What violation of mineral exchange is characteristic for patients with ulcerous illness of stomach and intestine
- A. hypocalcemia
 - B. * hypokaliemia
 - C. Hyponatremia
 - D. Hypercalcinemia
 - E. hyperkaliemia
1789. When apply Teylor's method at ulcerous illness
- A. * at conservative treatment perforated ulcers
 - B. at conservative treatment sanguifluous ulcers

- C. at conservative treatment penetration ulcers
 - D. at conservative treatment malignization ulcers
 - E. at conservative treatment of cicatrical pyloristhenosis
1790. When conservative treatment could be performed at perforative peptic ulcer?
- A. Bleeding peptic ulcer
 - B. If a atypical perforation
 - C. At the clinical picture of general peritonitis
 - D. In patients with tuberculosis
 - E. * If patient does not want operation
1791. When could be "rotten" belch ?
- A. At cholecystitis
 - B. At pancreatitis
 - C. At peptic ulcerative disease of stomach
 - D. At peptic ulcerative disease of duodenum
 - E. * At the cancer of stomach
1792. When could be symptom of fluctuation in abdominal cavity?
- A. At pancreatitis
 - B. At peptic ulcerative disease of stomach
 - C. At peptic ulcerative disease of duodenum
 - D. At chronic gastritis
 - E. * Ascitis
1793. When does a melena appear ?
- A. At pancreatitis
 - B. At peptic ulcerative disease of stomach
 - C. At peptic ulcerative disease of duodenum
 - D. At bleeding in the abdominal cavity
 - E. * At gastro-duodenal bleeding
1794. When is observed tension of muscles of stomach ?
- A. At pancreatitis
 - B. At peptic ulcerative disease of stomach
 - C. At peptic ulcerative disease of duodenum
 - D. At chronic gastritis
 - E. * At inflammation of peritoneum
1795. When small curvature of stomach is palpated?
- A. At gastritis
 - B. At decreasing of stomach
 - C. At increasing of stomach
 - D. In a norm
 - E. * At gastropnoia
1796. Where is located inferior measure of stomach?
- A. Below umbilicus on 3-4 cm
 - B. Above umbilicus on 7-8 cm
 - C. At the level of umbilicus
 - D. Below umbilicus on 2-3 cm
 - E. * Above umbilicus on 2-3 cm
1797. Which clinical sign is not characteristic for dumping-syndrome:

- A. A diarrhoea after eating
 - B. Pain in an epigastrium after food intake
 - C. Weakness, dizziness, hard beet filling after the food intake
 - D. A loss of weight, general weakness
 - E. * Vomiting by the eaten food
1798. Which disease is characterized by disappearance of pain in the epigastrium?
- A. Pancreatitis.
 - B. Cholecystitis.
 - C. Pyloroduodenal stenosis.
 - D. Perforation of peptic ulcer.
 - E. * Bleeding from an peptic ulcer.
1799. Which disease is characterized by melena?
- A. Penetration.
 - B. Malignancy .
 - C. Stenosis.
 - D. Perforation .
 - E. * Bleeding from an peptic ulcer.
1800. Which drug is prescribed at the gastro-duodenal bleeding:
- A. Vicalinum.
 - B. Baralgin
 - C. Paracetamol
 - D. Aspirin
 - E. * Dicinon.
1801. Which groups of preparations is prescribed for treatment of peptic ulcerous disease
- A. Antibiotics
 - B. Antiacid preparations
 - C. Histamin blockers
 - D. H-2 blockers
 - E. * Non-steroid antiinflammation drugs.
1802. Which symptoms is absent at perforative gastric peptic ulcer:
- A. Severe state of patient
 - B. Disappearance of hepatic sound.
 - C. Knife-like" pain
 - D. Wooden belly.
 - E. * Frequent vomiting.
1803. Why could be disappearance of hepatic sound at a perforative gastric peptic ulcer?
- A. A presence of liquid in abdominal cavity.
 - B. Swelling of intestine.
 - C. Interposition of intestinal loops between a liver and diaphragm.
 - D. High location of diaphragm.
 - E. * A presence of free gas in an abdominal cavity.
1804. Why during the operations at peptic ulcerous disease resection of 2/3 of stomach is performed:
- A. All of answers are correct.
 - B. All of answers are wrong.
 - C. By the features of blood supply of stomach.
 - D. By the features of lymph supply of stomach.

- E. * By the necessity to remove zones with hastrine and acid production.
1805. Wooden belly is characteristic for:
- A. Acute ileus
 - B. Colitis
 - C. Pancreatitis
 - D. Volvulus
 - E. * Perforative peptic ulcer
1806. A acute cholecystitis usually begins from:
- A. Paine in the left hypohondrium
 - B. Disorders of chair
 - C. High temperature
 - D. Vomiting
 - E. * Paine in the right hypohondrium
1807. A liquid in the cysts of pancreas:
- A. Milk-white
 - B. Green
 - C. Hemorrhagic
 - D. Brown grey
 - E. * Transparent or rather yellow
1808. A patient 40 years old, suffered ulcerous diseases of stomach. Last 2 days the pain became less intansive, but weakness and dizziness were appeare. Rose from a bed and lost consciousness. Pale. There are insignificant pains in epigastrium. It is
- A. Combination perforation with bleeding
 - B. Perforation
 - C. Malignization of ulcer
 - D. Stenosis of ulcer
 - E. * Gastroenteric bleeding
1809. A primary purpose of treatment of patients with fatty pancreonecrosis before operation is:
- A. Improvement of microcirculation
 - B. Decrease of secretion of pancreas
 - C. Decrease of secretion of stomach
 - D. Analgesia
 - E. * Desintoxication of organism
1810. A remittent icterus is caused:
- A. By the stricture of choledochus
 - B. Peptic ulcer disease
 - C. By the stone in cystic duct
 - D. By the tumor of choledochus
 - E. * By the valve stone of choledochus
1811. Absolute indication to operative treatment the ulcerous illness is
- A. heavy pain syndrome
 - B. * perforation of ulcer
 - C. relapses more than 2 one time per a year
 - D. ulcerous anamnesis more than 10 years
 - E. giant ulcers
1812. Absolute indication to operative treatment the ulcerous illness is

- A. * voluminous bleeding
 - B. callous ulcers
 - C. relapses more than 2 one time per a year
 - D. ulcerous anamnesis more than 10 years
 - E. heavy pain syndrome
1813. Absolute indication to operative treatment the ulcerous illness is
- A. ulcerous anamnesis more than 10 years
 - B. * bleeding what do not stopped with conservative
 - C. perforation ulcer in anamnesis
 - D. heavy pain syndrome
 - E. relapses more than 3 times per a year
1814. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. ulcerous anamnesis more than 10 years
 - C. relapse ulcer after the resection of stomach
 - D. relapses more than 3 times per a year
 - E. * cicatrical-ulcerous stenosis of pylorus
1815. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. * malignization ulcers
 - C. ulcerous anamnesis more than 10 years
 - D. heavy pain syndrome, proof heartburn
 - E. relapse ulcer after vagotomy
1816. Absolute sign of unstable hemostasis
- A. * profluvium blood from a vessel;
 - B. absence blood in a stomach and bulb of duodenum;
 - C. presence light blood and faltungs of blood in a stomach;
 - D. all answers are correct;
 - E. all answers are not correct
1817. According to time of origin of complications of acute pancreatitis is divided to:
- A. All true
 - B. All false
 - C. Primary and secondary
 - D. Urgent and non-urgent
 - E. * Early and late
1818. After what develops postnecrotic cysts of pancreas?
- A. Acute pancreatitis, edematous form
 - B. Chronic indurative pancreatitis
 - C. Chronic pseudotumor- pancreatitis
 - D. Chronic pancreatitis
 - E. * Acute pancreatitis, pancreonecrosis
1819. After what operation at ulcerous illness the natural arcade of meal is saved on a digestive tract
- A. Valter-Braun's gastroenterostomy
 - B. not saved after any operation
 - C. resection by Bilrot II
 - D. * resection by Bil'rot I

- E. saved after all transferred operations
1820. After what operation innervation of pyloric department of stomach is saved
- A. * selective vagotomy
 - B. barrel vagotomy
 - C. selective proximal vagotomy
 - D. at all transferred
 - E. not saved after all operations
1821. An optimum volume of operation is at a acute biliary pancreatitis:
- A. Draining of bed of pancreas.
 - B. Removing of exudates from abdominal cavity;
 - C. Pancreatectomy;
 - D. Encapsulation of pancreas;
 - E. * Draining of bilious ways;
1822. An unreal pancreatitis cyst contains:
- A. Sinovial liquid
 - B. Gastric juice
 - C. Serous liquid
 - D. Rudiments of teeth, hairs, nails
 - E. * Blood, pancreatitis juice, products of necrosis of pancreas
1823. As a rule, a pseudocyst contains:
- A. Water
 - B. Lymph
 - C. Pus
 - D. Bile
 - E. * Pancreatic juice
1824. At a acute and chronic cholecystitis contra-indicated drugs:
- A. Baralginum
 - B. Atropinum sulfate
 - C. Nospanum
 - D. Omnoponum
 - E. * Morphinum
1825. At a pseudo-tumorous pancreatitis a basic symptom is:
- A. Portal hypertension
 - B. Suppuration
 - C. Pseudocysts
 - D. Paine
 - E. * Intensive mechanical jaundice
1826. At acute pancreatitis with heavy motion a patient must be treated in:
- A. True answer is absent
 - B. All of answers are true
 - C. Home
 - D. Surgical department
 - E. * Department of intensive therapy
1827. At beginning bleeding from an ulcer
- A. * pain diminishes
 - B. pain increases

- C. there is knife-like pain
 - D. character of pain does not change
 - E. girdle pain
1828. At bleeding emergency operative interferences are executed
- A. * to 3 hours
 - B. to 1,5 hour
 - C. to 6 hours
 - D. to 8 hours
 - E. 6 – 12 hours
1829. At gallstone disease cholecystectomy is performed:
- A. At young persons
 - B. At old patients
 - C. At presence of clinical signs of disease
 - D. At the latent form of disease
 - E. * Always
1830. At III stage blood loss at the bleeding ulcer the patient loses
- A. over 1000 ml blood
 - B. * over 2000 ml blood
 - C. over 500 ml blood
 - D. over 2500 ml blood
 - E. over 1500 ml blood
1831. At III stage blood loss at the bleeding ulcer the patient loses
- A. more than 25 % blood volume
 - B. * more than 30 % blood volume
 - C. more than 20 % blood volume
 - D. more than 15 % blood volume
 - E. more than 35 % blood volume
1832. At lung complication of acute pancreatitis respiratory insufficiency is characterized:
- A. By absence of all listed symptoms
 - B. By a frequent superficial breath
 - C. Acrocyanosis
 - D. By the short breath
 - E. * By the presence of all listed symptoms
1833. At the complicated pancreatitis conservative therapy indicated for:
- A. Decreasing of secretion of stomach
 - B. Decreasing of secretion of pancreas
 - C. Treatment of shock
 - D. Decreasing of pain
 - E. * All listed true
1834. At the complicated pancreatitis, bleeding could be from vessels, except:
- A. Left gastric artery
 - B. Gastro-duodenal artery
 - C. Splenic vein
 - D. Splenic artery
 - E. * Hepatic artery
1835. At the destructive forms of acute pancreatitis all surgical operations are divided on:

- A. Not divided
 - B. With complications, without complications
 - C. Invasive, non-invasive operations
 - D. Primary, secondary, repeated operations
 - E. * Early, late, delay operation
1836. At the duodenum ulceroperation of choice is
- A. * resection by Bilrot I
 - B. resection by Bilrot II
 - C. resection of duodenum
 - D. selective proximal vagotomy
 - E. sewing up of ulcer
1837. At the gastroenteric bleeding the middle degree of blood loss is diagnosed at next indexes
- A. Hb below 80 g/l
 - B. * Hb 80-100 g/l
 - C. red corpuscles below $2,5 \cdot 10^{12}/l$
 - D. red corpuscles of $3,5-4,0 \cdot 10^{12}/l$
 - E. Ht below 25%
1838. At the III item of activity hemostasis and III sage blood loss from the I – III sage blood loss indicated
- A. * urgent operations (6 – 12 hours);
 - B. emergency operations (to 3 hours);
 - C. exigent operations (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
1839. At the V item activity of hemostasis and at the recurrent bleeding of the I – III item of blood loss indicated
- A. * emergency operations (to 3 hours);
 - B. urgent operations (6 – 12 hours);
 - C. exigent (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
1840. At ulcerous illness can a bleeding source be
- A. artery;
 - B. veins;
 - C. shallow vessels and ulcers;
 - D. all answers are not correct.
 - E. * all answers are correct
1841. Bergman's sing is characteristic for
- A. * bleeding ulcer
 - B. for cicatrical-ulcerous pylorostenosis
 - C. perforated ulcers
 - D. penetration ulcers
 - E. malignization ulcers
1842. Berhtein's sing characteristic for
- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers

- D. malignized ulcers
 - E. for cicatrical-ulcerous pylorostenosis
1843. Bleeding ulcer, complicated blood loss III stage degrees, requires
- A. * blood and its components transfusions
 - B. transfusion of salt solutions
 - C. transfusion of colloid solutions
 - D. transfusion of salt and colloid solutions
 - E. infusion therapy does not need
1844. Blood loos I stage characterized such indexes
- A. Ht 48-44, Hb 120
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 31-23, Hb 80
 - D. * Ht 38-32, Hb 100
 - E. Ht 44-40, Hb 110 /?
1845. Blood loos II stage characterized
- A. * Ht 23 and below, Hb 50 and below
 - B. Ht 31-23, Hb 80
 - C. Ht 44-40, Hb 110
 - D. Ht 48-44, Hb 120
 - E. Ht 48-44, Hb 120
1846. Blood loos III stage characterized a degree such indexes
- A. * Ht 31-23, Hb 80
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 38-32, Hb 100
 - D. Ht 44-40, Hb 110
 - E. Ht 48-44, Hb 120
1847. Blood supply of body and tail of pancreas is:
- A. Variously
 - B. A.cystica
 - C. A.gastrica sinistra
 - D. A.gastroduodenalis
 - E. * Splenic artery
1848. By localization complications of acute pancreatitis are divided to:
- A. Pancreatic
 - B. Ekstraabdominal
 - C. Intraabdominal
 - D. Parapancreatic
 - E. * All of answers are true
1849. Cells of pancreas, which are makes glucagone:
- A. Z-cells
 - B. Y-cells
 - C. X-cells
 - D. W-cells
 - E. * B-cells
1850. Cells of pancreas, which are makes insulin:
- A. Z-cells

- B. Y-cells
 - C. X-cells
 - D. W-cells
 - E. * B-cells
1851. Classification of clinical passing of acute pancreatitis:
- A. All true
 - B. Edema, necrosis
 - C. Easy, middle, heavy
 - D. Acute, chronic
 - E. * Abortive, progressive
1852. Clinical signs of acute pancreatitis:
- A. Constipation
 - B. Vomiting by blood
 - C. Melena
 - D. Vomiting by „coffee-grounds”
 - E. * There is a pain in the epigastria
1853. Complaints of the patient with pseudo-tumorous pancreatitis:
- A. Yellow color of the skin
 - B. Icterus
 - C. Dispeptic syndrome
 - D. Pain in the epigastric region
 - E. * All of answers are true
1854. Complication of choledocholitis is:
- A. Perforative cholecystitis, peritonitis
 - B. Chronic hepatitis
 - C. Hydrocholecystitis
 - D. Empyema of gall-bladder
 - E. * Icterus, cholangitis
1855. Complications of acute pancreatitis is not:
- A. Omentobursitis
 - B. Biliary hypertension
 - C. Fermentativ peritonitis
 - D. Pylephlebitis
 - E. * Phlegmon of retroperitoneal space
1856. De-Cerven's sign is characteristic for
- A. bleeding ulcer
 - B. * perforated ulcers
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatrical-ulcerous pylorostenosis
1857. Diet at bleeding gastric and duodenum ulcers
- A. * Meulengracht's
 - B. 1 by Pevznerom
 - C. 5 by Pevznerom
 - D. 15 by Pevznerom
 - E. 7 by Pevznerom

1858. Disappearance or diminishing the pain with beginning of bleeding from an ulcer is
- A. * Bergman's sign
 - B. Spazarskiy's sign
 - C. Mendel's sign
 - D. De Keven's sign
 - E. Eleker's sign
1859. Duration the period of primary shock at a perforated ulcer
- A. * 3-6 hours
 - B. 6-12 hours
 - C. 1-3 hours
 - D. 12-24 hours
 - E. 24-36 hours
1860. Early complication at acute pancreatitis is:
- A. Acute ileus
 - B. Development of diabetes
 - C. Formation of pseudocysts
 - D. Phlegmon of retroperitoneal space
 - E. * Peritonitis
1861. Early complication of acute pancreatitis is not:
- A. True answer is absent
 - B. Enzymes peritonitis
 - C. Collapse
 - D. Pancreatic shock
 - E. * Fistula of pancreas
1862. Eleker's sign is characteristic for
- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorostenosis
1863. Endoscopic papillosphincterotomy is indicated at such disease, as:
- A. Mechanical jaundice
 - B. Hepatitis
 - C. Postcholecystectomy syndrome
 - D. Peptic ulcer
 - E. * Stenosis of supraduodenal part of choledochus
1864. Esophagogastroduodenoscopy can find out next changes in a stomach, except for
- A. tumours
 - B. ulcers
 - C. bleeding polypuses
 - D. erosions
 - E. * changes of evacuation function
1865. Ferment's peritonitis can arise up in the case of disease of such organs of abdominal cavity:
- A. Stomach
 - B. Gall-bladder
 - C. Liver
 - D. Spleen

- E. * Pancreas
1866. Ferment's peritonitis in patients with acute pancreatitis develops:
- A. After 72 hours
 - B. In 5-6 days
 - C. In 12-15 hours
 - D. In 6 hours from the beginning of disease
 - E. * In the period of 24-48 hours
1867. Fermentativ shock at the complicated pancreatitis more frequent arises up at:
- A. Chronic pancreatic fistula
 - B. Abscess of pancreas
 - C. To the edema of pancreas
 - D. Local necrosis of pancreas
 - E. * Subtotal or total necrosis of pancreas
1868. For a cholangitis the most characteristic combination of symptoms: 1) icterus 2) fever 3) anaemia 4) leucocytosis 5) peritonitis
- A. 2,3,5
 - B. 2,5
 - C. 3,4,5
 - D. 1,2,3
 - E. * 1,2,4
1869. For a mechanical icterus, with choledolithiasis, not characteristic:
- A. absence of stercobilin in stool
 - B. hypertermia
 - C. increase of alkaline phosphatase
 - D. Increasing of direct bilirubin of blood
 - E. * An acute increasing of level of amylase is in plasma
1870. For acute cholangitis not characteristic:
- A. High temperature
 - B. Leucocytosis
 - C. Icterus
 - D. Pain in right hypochondrium
 - E. * Unsteady liquid stool
1871. For acute cholangitis not characteristic:
- A. increase of liver
 - B. leucocytosis with shift of formula to the left
 - C. icterus
 - D. increase of temperature
 - E. * decreasing of sizes of liver
1872. For bleeding ulcer characteristic sign is
- A. * pain in an epigastrium;
 - B. knife-like pain;
 - C. signs irritation of peritoneum;
 - D. presence fresh blood in incandescence
 - E. melena;
1873. For bleeding ulcer characteristically
- A. * melena

- B. tension the muscles of front abdominal wall
 - C. Spazarskiy's sign
 - D. sickliness the back vault of vagina
 - E. irradiation pain in a shoulder or shoulder-blade
1874. For clarification of character of icterus and its reason of origin not used:
- A. Sonography
 - B. ERCP
 - C. transcutaneous transhepatic cholangiography
 - D. CT
 - E. * intravenous cholecystocholangiography
1875. For motion of disease ulcerous illness of middle weight characteristically
- A. development of complications
 - B. * relapses 1-2 times per a year
 - C. 4 and anymore relapses on a year
 - D. 5 and more relapses are on a year
 - E. 3 and anymore relapses on a year
1876. For patient with gangrenous cholecystitis it is indicated:
- A. Conservative treatment
 - B. Without operation
 - C. Tactic depends from age
 - D. An operation is deferred
 - E. * Urgent operation
1877. For perforated ulcer characteristically
- A. * tension the muscles of front abdominal wall
 - B. melena
 - C. vomiting by coffee-grounds
 - D. high intestinal impassability
 - E. vomiting stagnant gastric maintenance
1878. For pneumoperitoneum is characteristic symptom
- A. * Zhober's;
 - B. Khelatid's;
 - C. Podlag's;
 - D. Vigats's;
 - E. Udin's.
1879. For the heavy flow of ulcerous illness characteristically
- A. 2 and anymore relapses on a year
 - B. * 3 and anymore relapses on a year
 - C. 4 and anymore relapses on a year
 - D. 5 and more relapses are on a year
 - E. 6 and more relapses are on a year
1880. For the heavy flow of ulcerous illness characteristically
- A. * development of complications
 - B. seasonal exacerbation more not frequent 1-2 times per a year
 - C. 1-2 relapse on a year
 - D. liquid, but protracted exacerbation
 - E. exacerbation duration more than 10 days

1881. Forming of pancreatic infiltrate is depended from:
- A. Toxic influence
 - B. Autoimmune inflammation
 - C. Septic inflammation
 - D. Allergic reaction
 - E. * Aseptic inflammation
1882. Frequency of hepatic insufficiency at complicated acute pancreatitis:
- A. In 95 % patients
 - B. In 2 % patients
 - C. In 75 % patients
 - D. In 100 % patients
 - E. * In 25 % patients
1883. From what department degestive tract developmentp more frequent than all the bleeding at the Mallory-Weiss syndrome
- A. gastric fundus
 - B. * cardial pert;
 - C. pyloric department;
 - D. from duodenal;
 - E. from a thick intestine
1884. Gallstone disease is complicated by all of listed, except:
- A. Mechanical jaundice
 - B. Development of destructive cholecystitis
 - C. Secondary pancreatitis
 - D. Cancer of gall-bladder
 - E. * Development of cirrhosis of liver
1885. Gallstone disease is not complicated:
- A. Cholangitis
 - B. Fistula
 - C. By acute cholecystitis
 - D. By mechanical icterus
 - E. * Intra-abdominal bleeding
1886. Giant ulcer is an ulcer measuring
- A. over 4,5 cm
 - B. * over 3 cm
 - C. over 4 cm
 - D. over 5 cm
 - E. over 3,5 cm
1887. Hemobilia is
- A. * all answers are correct;
 - B. bleeding the bilious ways and liver;
 - C. bleeding the general bilious channel;
 - D. bloody clot in the big duodenal papilla;
 - E. all answers are not correct.
1888. Holsted symptom at acute pancreatitis is:
- A. Cyanosis of hands
 - B. Yellow skin around umbilicus
 - C. Violet spots are on face and body

- D. Cyanosis of lateral surfaces of abdomen and body
 - E. * Cyanosis of skin of abdomen
1889. Hormone of pancreas which is responsible for metabolic of fat:
- A. Somatotropinum
 - B. Adrenalin
 - C. Insulin
 - D. Glukagon
 - E. * Lipocainum
1890. How often pancreatic part of common bile duct pass through the head of pancreas?
- A. 40-50 %
 - B. 30-40 %
 - C. 25-35 %
 - D. 10-20 %
 - E. * 80-90 %
1891. If patient has frequent „fatty stool” with undigested meat, it could be:
- A. Cirrhosis of liver
 - B. Ulcerous disease of duodenum
 - C. Chronic hepatitis
 - D. Chronic duodenitis
 - E. * Chronic pancreatitis
1892. In case of acute pancreatitis bleeding could be to:
- A. Intestine (at internal fistula)
 - B. Abdominal cavity
 - C. Wound
 - D. External fistula
 - E. * At all listed variants
1893. In case of purulent inflammation of the pseudocysts of pancreas is used:
- A. Cystoenteroanastomosis
 - B. Cystoduodenostomy
 - C. Cystogastrostomy
 - D. Cystoenterostomy
 - E. * External draining of cyst
1894. In relation to peritoneum pancreas is located:
- A. All of answers are correct
 - B. All of answers are incorrect
 - C. Intraperitoneally
 - D. Mesoperitoneally
 - E. * Retroperitoneally
1895. In the case of gallstone disease urgent operation is indicated:
- A. At a hepatic colic
 - B. At mechanical joundice
 - C. At occlusion of cystic duct
 - D. At Cholecysto-pancreatitis
 - E. * At perforative cholecystitis
1896. In the case of surgical treatment of the complicated acute pancreatitis does not used:
- A. Right-side resection of gland

- B. Left-side resection of gland
- C. Omentopancreatopexy
- D. Abdominisation of pancreas
- E. * Pankreatojejunostomy

1897. In what area of stomach practically never is not origin of ulcers, or it is extraordinarily rarely?

- A. small curvature of stomach;
- B. back wall of stomach, nearer to small curvature;
- C. large curvature of stomach
- D. * cardiac part of stomach;
- E. pylorus.

1898. In what vein is a venous outflow carried out in from a stomach?

- A. * V. Portae;
- B. V. odd;
- C. V. pair;
- D. V. overhead hollow;
- E. V. lower hollow;

1899. Intraoperative cholangiography is not indicated:

- A. At icterus during the operation
- B. At dilatation of choledochus
- C. At presence of icterus in anamnesis
- D. At tumor of head of pancreas
- E. * At a single large stone in the common bile duct

1900. Irradiation of pain to the back could be in case of:

- A. Acute cystitis
- B. Gastric ulcers
- C. Acute ileus
- D. Acute cholecystitis
- E. * Acute pancreatitis

1901. Large ulcer is an ulcer measuring

- A. 1-4 cm
- B. 1-3 cm
- C. 3-5 cm
- D. 2- 6 cm
- E. * 2-3 cm

1902. Late complications at acute pancreatitis are:

- A. Acute ileus
- B. Shock
- C. Renal insufficiency
- D. Peritonitis
- E. * Phlegmon of retroperitoneal space

1903. Late complications of acute pancreatitis are:

- A. Cysts and fistula of pancreas
- B. Abscesses of abdominal cavity
- C. Phlegmon retroperitoneal tissue
- D. Festering pancreatitis and parapancreatitis
- E. * All of answers are true

1904. Little ulcer it is an ulcer measuring
- A. * to 0,5 cm
 - B. 0,5-1 cm
 - C. to 1,0 cm
 - D. 3 to 1,5 cm
 - E. 0,5-1,5 cm
1905. Lung complications is includes:
- A. Bronchial asthma
 - B. Pulmonary insufficiency
 - C. Abscess of lights
 - D. Right-side pleurisies and pneumonias
 - E. * Left-side pleurisies and pneumonias
1906. Main reason of acute pancreatitis is:
- A. Achalasia
 - B. Chronic alcoholic pancreatitis
 - C. Alimentary factor
 - D. Trauma of pancreas
 - E. * Gallstone disease
1907. Meets the most frequent localization bleeding the digestive tract is
- A. gullet;
 - B. stomach;
 - C. rectum;
 - D. * duodenum;
 - E. colon
1908. Melena is
- A. black designed chair
 - B. * black liquid tarry chair
 - C. a discoloured liquid excrement
 - D. foamy stinking emptying of black
 - E. an excrement designed veined blood
1909. Melena is a characteristic sign
- A. * bleeding ulcer
 - B. for cicatrical-ulcerous pylorus stenosis
 - C. perforeted ulcers
 - D. penetration ulcers
 - E. malignization ulcers
1910. Method of instrumental examination of pseudocysts is:
- A. Biopsy
 - B. Endoscopy
 - C. Colonoscopy
 - D. Sciagraphy of organs of abdominal cavity
 - E. * Sonography of organs of abdominal cavity
1911. Mondor symptom at acute pancreatitis is:
- A. Cyanosis of hands
 - B. Yellow skin around umbilicus
 - C. Cyanosis of skin of abdomen

- D. Cyanosis of lateral surfaces of abdomen and body
 - E. * Violet spots are on face and body
1912. Most informing method at a bleeding ulcer
- A. survey sciagraphy the organs of abdominal region
 - B. * EFGDS
 - C. sciagraphy the stomach with contrasting
 - D. Sonography
 - E. Laparoscopy
1913. Mostly a intoxication psychosis can arise up at abuse of:
- A. Smoking
 - B. Medicines
 - C. Drugs
 - D. Fatty food
 - E. * Alcohol
1914. Name class complications of ulcerous illness
- A. bleeding, pylorostenosis, second pancreatitis, malignization, perforation
 - B. * perforation, penetration, bleeding, pylorostenosis, malignization
 - C. malignization, pylorostenosis, penetration, anaemia, perforation
 - D. bleeding, perforation, second pancreatitis, anaemia, malignization
 - E. perforation, peritonitis, pancreatitis, bleeding, penetration
1915. Name specific complications of acute pancreatitis in early and late postoperative periods:
- A. Phlegmon of retroperitoneal space
 - B. Pseudocyst of pancreas
 - C. Fistula of pancreas
 - D. Bleeding
 - E. * All of answers are true
1916. Necrectomy of pancreas is mean:
- A. True answer is absent
 - B. Complete removing of pancreas
 - C. Removing of part of pancreas with its transversal cutting
 - D. Removing of necrotic area within the measures of necrotic tissue
 - E. * Removing of necrotic area is within the limits of healthy tissue
1917. Normal indexes of білірубіну of blood:
- A. 60,6-80,5 mmol/l
 - B. 40,6-60,5 mmol/l
 - C. 20,6-40,5 mmol/l
 - D. 0-1,6 mmol/l
 - E. * 1,7-20,5 mmol/l
1918. Operating access at operations on a stomach
- A. * Upper-middle laparotomy
 - B. Lower-middle laparotomy
 - C. Pararectum access
 - D. Volokovich-Dyakonov's access
 - E. Pfanenhtil's access
1919. Pancreatectomy is mean:
- A. True answer is absent

- B. Removing of necrotic area within the measures of necrotic tissue
 - C. Removing of necrotic area is within the limits of healthy tissue
 - D. Removing of part of pancreas with its transversal cutting
 - E. * Complete removing of pancreas
1920. Patient which the gastroenteric bleeding in house is necessary
- A. * To send a patient in surgical permanent establishment
 - B. To appoint rest, enter Cacl, vicasol
 - C. To wash a stomach, appoint a cold, rest of supervision
 - D. To send a patient in a therapeutic gastroenterology separation
 - E. A right answer absents
1921. Principle of conservative treatment of fistula of pancreas:
- A. Conservative treatment is non-effective
 - B. Improvement of outflow of bile
 - C. Increase of regeneration
 - D. Increase of pancreatic secretion
 - E. * Decrease of pancreatic secretion
1922. Radical operation at a bleeding gastric ulcer and duodenum consists in
- A. sewing vessels on a draught;
 - B. * vagotomy or resection the stomach;
 - C. sewing vessels in an ulcer;
 - D. gastroenteroanastomosis;
 - E. all answers are faithful
1923. Relative absolute indication to operative treatment ulcerous illness is
- A. * penetration of ulcer
 - B. ulcerous anamnesis more than 15 years
 - C. malignization ulcers
 - D. perforation of ulcer
 - E. relapses more than 3 times per a year
1924. Resection of pancreas is mean:
- A. True answer is absent
 - B. Complete removing of pancreas
 - C. Removing of necrotic area within the measures of necrotic tissue
 - D. Removing of necrotic area is within the limits of healthy tissue
 - E. * Removing of part of pancreas with its transversal cutting
1925. Resection of stomach by Bilrot II belongs to
- A. * radical operation
 - B. palliative operation
 - C. draining operations
 - D. organ protect operation
 - E. does not belong to any group
1926. Result of hypersecretion of pancreas can be the spasm of sphincter:
- A. Heyster
 - B. Vestfal
 - C. Mirizzi
 - D. Lutkins
 - E. * Oddi

1927. Sekvestrectomy of pancreas is mean:
- A. True answer is absent
 - B. Complete removing of pancreas
 - C. Removing of part of pancreas with its transversal cutting
 - D. Removing of necrotic area is within the limits of healthy tissue
 - E. * Removing of necrotic area within the measures of necrotic tissue
1928. Selective proximal vagotomy belongs to
- A. palliative
 - B. draining
 - C. * organ protect operation
 - D. resection
 - E. does not belong to any group
1929. Septic complications of acute pancreatitis is indication to:
- A. Analgesic treatment
 - B. Antibiotic treatment
 - C. Conservative treatment
 - D. Sonography
 - E. * Operation
1930. Signs of stable hemostasis
- A. * absence blood in a stomach and duodenum bulb;
 - B. presence the light blood and faltungs of blood in a stomach;
 - C. profluvium blood from a vessel;
 - D. all answers correct;
 - E. all answers are not correct
1931. Signs of unstable hemostasis
- A. * the pulsation of vessel is determined;
 - B. the bottom ulcer is covered a fibrin;
 - C. profluvium blood from a vessel;
 - D. all answers are correct;
 - E. all answers are not correct.
1932. Specify indication to early operative treatment at acute pancreatitis:
- A. Forming of pseudocyst
 - B. Acute fatty pancreatitis
 - C. Acute edematous pancreatitis
 - D. Acute pancreatolysis
 - E. * Acute traumatic pancreatitis
1933. Specify indication to early operative treatment at acute pancreatitis:
- A. Forming of pseudocyst
 - B. Acute fatty pancreatitis
 - C. Acute oedematous pancreatitis
 - D. Acute pancreatolysis
 - E. * Acute biliary pancreatitis
1934. Specify one of symptoms, what not characteristic for hydropsy of gallbladder:
- A. Absence of peritoneal symptoms
 - B. palpable gall-bladder
 - C. Increase of gall-bladder
 - D. Pains in right hypohondrium

- E. * Icterus
1935. Specify the best therapy of parapancreatic infiltrate:
- A. Operative treatment
 - B. Antispastic
 - C. Analgesic treatment
 - D. Desintoxication
 - E. * Antibiotic
1936. Specify the most dangerous complication of pancreonecrosis:
- A. Pseudocyst of pancreas
 - B. Diabetes
 - C. Inflammation
 - D. Fibrosis of pancreas
 - E. * Bleeding
1937. Specify the most effective treatment of the formed non-complicated cyst:
- A. Cystogastrostomy
 - B. External draining of cyst
 - C. A resection of cyst
 - D. Conservative treatment
 - E. * Cystoenteroanastomosis
1938. Specify the most effective treatment of the non-formed complicated cyst:
- A. Cystogastrostomy
 - B. Cystoenteroanastomosis
 - C. A resection of cyst
 - D. Conservative treatment
 - E. * External draining of cyst
1939. Specify the norm of diastase:
- A. Up to 10
 - B. Up to 30
 - C. Up to 20
 - D. Up to 50
 - E. * Up to 160
1940. Specify what pathology is reason of development of pseudocyst of pancreas:
- A. Liver cirrhosis
 - B. Peptic ulcer
 - C. Diabetes
 - D. Acute cholecystitis
 - E. * Acute pancreatitis
1941. Symptom of Bonde at acute pancreatitis is:
- A. Cyanosis of hands
 - B. Yellow skin around umbilicus
 - C. Cyanosis of skin of abdomen
 - D. Cyanosis of lateral surfaces of abdomen and body
 - E. * Swelling of abdomen only in the epigastric area
1942. Symptom of Kerte at a acute pancreatitis it:
- A. Hyper seniti of skin in the projection of gland
 - B. Yellow skin around umbilicus

- C. Absence of pulsation of abdominal aorta
 - D. Pain in left costal-vertebral area
 - E. * Pain and proof tension of muscles in the epigastria with irradiation to left hypochondria
1943. Symptom of Kulen at acute pancreatitis is:
- A. Cyanosis of hands
 - B. Violet spots are on face and body
 - C. Cyanosis of skin of abdomen
 - D. Cyanosis of lateral surfaces of abdomen and body
 - E. * Yellow skin around umbilicus
1944. Symptom of Meyo-Robson at acute pancreatitis is:
- A. Hyper seniti of skin in the projection of gland
 - B. Yellow skin around umbilicus
 - C. Pain and proof tension of muscles in the epigastria with irradiation to left hypochondria
 - D. Absence of pulsation of abdominal aorta
 - E. * Pain in left costal-vertebral area
1945. Symptom of Voskresensky at acute pancreatitis is:
- A. Hyper seniti of skin is in the projection of gland
 - B. Yellow skin around umbilicus
 - C. Pain and tension of muscles in the epigastria
 - D. Pain in the left costal-vertebral area
 - E. * Absence of pulsation of abdominal aorta
1946. The basic method ofexamination of acute cholecystitis is:
- A. Gastroduodenoscopy
 - B. Laparoscopy
 - C. Cholegraphy
 - D. Endoscopy
 - E. * Sonography of gall-bladder
1947. The best time of operative treatment at acute pancreatitis after beginning of disease is:
- A. 7-8 days
 - B. 3-4 days
 - C. 4-5 days
 - D. 1-3 days
 - E. * Surgical treatment is not indicated
1948. The diameter of ductus choledochus is :
- A. over 2,0 cm
 - B. 1,6-2,0 cm
 - C. 1,1-1,5 cm
 - D. to 0,5 cm
 - E. * 0,6-1,0 cm
1949. The early bleeding at the complicated acute pancreatitis are more frequent:
- A. In the first minute
 - B. During the first hour
 - C. During the first minute
 - D. At a few first hours
 - E. * In a few first days

1950. The early bleeding at the complicated pancreatitis is stopped by using:
- A. Cold on the abdomen
 - B. Hot-water bottles on the abdomen
 - C. Rest and cold on the abdomen
 - D. Operative treatment
 - E. * Ordinary haemostatic drugs
1951. The first period of acute pancreatitis has the name:
- A. A right answer is absent
 - B. All of answers are true
 - C. Degenerative and festering complications
 - D. Functional insufficiency of parenchyma's organs
 - E. * Hemodynamic violations and pancreatic shock
1952. The most frequent complication after ERCP is:
- A. Chronic hepatitis
 - B. Reactive cholecystitis
 - C. Pancreatic sepsis
 - D. Cholangitis
 - E. * Pancreatitis
1953. The most informing method for diagnostics of acute pancreatitis is:
- A. Colonoscopy
 - B. Duodenodcopy
 - C. Endoscopy
 - D. ECG
 - E. * Sonography
1954. The nosotropic mechanisms bleedingness at ulcerous illness is
- A. * all answers are correct.
 - B. permanent hyperemia all system of stomach
 - C. different degree dystrophy of superficial layers the mucus shell
 - D. accumulation the central mucopolysaccharides
 - E. hypoplastic, dystrophic processes
1955. The period of degenerative complications has:
- A. 2 hours
 - B. 2 weeks
 - C. 1-3 days
 - D. 3-7 days
 - E. * over 7 days
1956. The period of functional insufficiency of abdominal organs has:
- A. 2 hours
 - B. 2 weeks
 - C. over 7 days
 - D. 1-3 days
 - E. * 3-7 days
1957. The period of hemodynamic violations and pancreatic shock has:
- A. 2 hours
 - B. 2 weeks
 - C. over 7 days

- D. 3-7 days
 - E. * 1-3 days
1958. The principle of operation at acute biliary pancreatitis:
- A. Draining of parapancreatic tissue
 - B. Removing of fluid from abdominal cavity
 - C. Pancreatectomy
 - D. Decapsulation of pancreas
 - E. * Draining of bile ducts
1959. The reason of development of mechanical jaundice can be all, except
- A. Stenosis of duodenal papilla
 - B. Stricture of the choledochus
 - C. Stone in proximal part of choledochus
 - D. Increase of head of pancreas
 - E. * To the stone in the area of neck of gall-bladder
1960. The second period of acute pancreatitis has the name:
- A. A right answer is absent
 - B. All of answers are true
 - C. Degenerative and festering complications
 - D. Hemodynamic violations and pancreatic shock
 - E. * Functional insufficiency of parenchyma's organs
1961. The secretory function stomach is carried out the next membrane of stomach
- A. * mucous membrane
 - B. internal muscular layer
 - C. serosal
 - D. mucous submembrane
 - E. external layer
1962. The symptom of Curvuasie is not observed at cancer of:
- A. Head of pancreas
 - B. Duodenal papilla
 - C. Retroduodenal part of common bile duct
 - D. Supraduodenal part of choledochus
 - E. * Gall-bladder
1963. The symptoms of intoxication psychosis at the complicated acute pancreatitis is:
- A. Visual hallucinations
 - B. Aggression
 - C. Apathy
 - D. Hypodynamia
 - E. * Disorientation
1964. The third period of acute pancreatitis has the name:
- A. A right answer is absent
 - B. All of answers are true
 - C. Hemodynamic violations and pancreatic shock
 - D. Functional insufficiency of parenchyma's organs
 - E. * Degenerative and festering complications
1965. To absolute indication to operative interference at ulcerous illness does not belong
- A. * scarry-ulcerous stenosis

- B. perforation of ulcer
 - C. profuse bleeding
 - D. diameter ulcer a more than 3 cm
 - E. bleeding what does not stopped with conservative
1966. To the gastric – intestinal bleeding of un ulcerous etiology belong
- A. * Mallory-Weiss syndrome;
 - B. hemorrhagic erosive gastritis;
 - C. diseases by Randyu – Oslera – Vebera;
 - D. Menetrie's sing;
 - E. all answers are correct.
1967. Total pancreonecrosis is characterized by:
- A. Increasing of AST
 - B. Decreasing of activity of diastase
 - C. Increasing of ALT
 - D. Decreasing of AST
 - E. * Increasing of activity of diastase
1968. Turner symptom at acute pancreatitis is:
- A. Cyanosis of hands
 - B. Yellow skin around umbilicus
 - C. Cyanosis of skin of abdomen
 - D. Violet spots are on face and body
 - E. * Cyanosis of lateral surfaces of abdomen and body
1969. Udin's sing at a perforated ulcer is
- A. * feeling at palpation shove the gases which penetrate through the perforated opening
 - B. dulling perforated sound in the lateral departments of stomach
 - C. disappearance of hepatic dullness
 - D. irradiation pain in a shoulder or shoulder-blade
 - E. sickliness the back vault of vagina
1970. Vomiting by „coffee-grounds” at acute pancreatitis is predefined:
- A. By presence of enzymes in blood
 - B. By violation of microcirculation
 - C. By the presence of concomitant gastric ulcer
 - D. By the presence of concomitant gastritis
 - E. * By formation of erosions in a stomach
1971. Vomiting coffee-grounds is a characteristic sign
- A. * bleeding ulcer
 - B. penetrative ulcers
 - C. perforated ulcers
 - D. malignizated ulcers
 - E. for cicatrical-ulcerous pylorus stenosis
1972. Vomiting what arose up in 4-6 hours after eating characteristic for
- A. chronic alcoholic gastritis
 - B. cancer and ulcers of cardia
 - C. * pylorus ulcers
 - D. achalasia of gullet
 - E. ulcer and cancer the body of stomach

1973. What are complications of acute pancreatitis:
- A. Phlegmon of retroperitoneal space
 - B. Biliary hypertension
 - C. Omentobursitis
 - D. Fermentativ peritonitis
 - E. * All indicated complication
1974. What are cysts of pancreas ?:
- A. Traumatic
 - B. Inflammatory
 - C. After echinococcus
 - D. Real and unreal
 - E. * All of answers are true
1975. What colouring of chair is most characteristic for bleeding from the ulcer of stomach and duodwnum?
- A. * Tarry excrement
 - B. Presence on the formed excrement of strokes of red blood
 - C. Littlechanged blood in an excrement
 - D. Excrement of the raspberry colouring with the admixtures of mucus
 - E. Acholic excrement
1976. What combination of clinical symptoms does explain the syndrome of Curvuasie?
- A. an icterus, enlarged liver
 - B. absence of stool, pain, appearance of formation in abdominal region
 - C. icterus, local peritoneal phenomena
 - D. increase of liver, hydro-peritoneum, expansion of veins of front abdominal wall
 - E. * A painless enlarged gall-bladder in combination with icterus
1977. What complication of acute pancreatitis?
- A. Paranepritis
 - B. Cyst of pancreas
 - C. Pylephlebitis
 - D. Abscess of Duglas space
 - E. * Pancreonecrosis
1978. What complication the ulcerous illness of stomach is most characteristically for the patients of elderly and senile age
- A. perforation
 - B. perforation + bleeding
 - C. pylorus stenosis
 - D. malignization + penetration
 - E. * bleeding
1979. What components is absent in urine at a mechanical jaundice?
- A. All are present
 - B. Bilious acids.
 - C. Not direct bilirubin.
 - D. Direct bilirubin.
 - E. * Urobilin.
1980. What does the pseudocyst of pancreas behave to?:
- A. All of answers are true
 - B. Symptom of acute pancreatitis

- C. Congenital pathology of pancreas
 - D. Early complication of acute pancreatitis
 - E. * Late complication of acute pancreatitis
1981. What drug is used at chronic pancreatitis with violation of the external function of pancreas?
- A. Panthenol
 - B. Pyracetamum
 - C. Pantocrinum
 - D. Papaverin
 - E. * Panzinorm
1982. What drugs from cytostatic group is used in acute pancreatitis:
- A. Mezimforte
 - B. Baralgin
 - C. Creon
 - D. Motilium
 - E. * 5-ftoruracyl
1983. What external signs are characteristic for the profuse bleeding from a gastric ulcer?
- A. Vomiting by the littlechanged blood, excrement of the raspberry colouring
 - B. * Vomiting by the littlechanged blood, tarry darkly-cherry chair
 - C. Vomiting by a complete mouth by dark blood with clots, black formed excrement
 - D. Vomiting on the type of "coffee-grounds", presence on the formed incandescence of strokes of red blood
 - E. Tarry darkly-cherry chair
1984. What from preparations has the expressed bacteriostatic action on Helicobacter pyloris
- A. * trichopol
 - B. Liciviroton
 - C. oxiferiskorbon
 - D. atropine
 - E. pirinzsipin
1985. What from the transferred operations does not belong to organ protective
- A. trunk vagotomy
 - B. * resection by Bilrot II
 - C. selective vagotomy
 - D. selective proximal vagotomy
 - E. the all transferred does not belong
1986. What from the transferred operations on the stomach organ protective is
- A. * selective proximal vagotomy
 - B. resection by Bilrot I
 - C. resection by Bilrot II
 - D. gastrectomy
 - E. all are transferred
1987. What hormone of pancreas responsible for metabolism of glucose:
- A. Tiroksin
 - B. Somatotropinum
 - C. Adrenalin
 - D. Vasopressinum
 - E. * Insulin

1988. What hormones undertake the protective operating on the mucous membrane of stomach, except for
- A. * ACTH
 - B. epidermal factor of growth
 - C. prostaglandin E
 - D. estrogens
 - E. STH
1989. What indications for surgical treatment of cholecystitis?
- A. Dispeptic syndrome
 - B. presence of pancreatitis
 - C. Concomitant changes in a liver
 - D. Anamnesis of disease
 - E. * Presence of stones in the gall-bladder
1990. What is complication of acute pancreatitis:
- A. Hepatitis
 - B. Cyst of pancreas
 - C. Cirrhosis of liver
 - D. Pylephlebitis
 - E. * Pankreonekrosis
1991. What is conservative treatment before operation in patients with severe form of hemorrhagic pancreonecrosis:
- A. Improvement of microcirculation
 - B. Decrease of secretion of pancreas
 - C. Decrease of secretion of stomach
 - D. Analgesia
 - E. * Desintoxication of organism
1992. What is early complications of acute pancreatitis?
- A. Shock
 - B. Jaundice
 - C. Peritonitis
 - D. Acute hepatic-renal insufficiency
 - E. * All of answers are true
1993. What is included in conservative treatment of acute pancreatitis?
- A. Morning exercises
 - B. High caloric diet
 - C. A diet by Pevzner N15
 - D. A diet by Pevzner N5
 - E. * Hunger
1994. What is local symptoms of retroperitoneal phlegmon at complicated acute pancreatitis?
- A. Hyperemia of tissue
 - B. Swelling of tissue
 - C. Tension of lumbar muscles
 - D. Pain during palpation on the left hypochondrium
 - E. * All of symptoms true
1995. What is mechanism of Voskresensky symptom at acute pancreatitis:
- A. Development of peritonitis
 - B. Embolism of abdominal aorta

- C. Thrombosis of abdominal aorta
 - D. Reflex-paresis of colon
 - E. * Inflammatory edema of pancreas
1996. What is not inhibitors of protease:
- A. Pantripin
 - B. Trasilol
 - C. Gordoxum
 - D. Kontrikal
 - E. * Tebris
1997. What is result of pancreatic infiltrate:
- A. Development of pseudocyst
 - B. Distribution of process with development of peritonitis
 - C. Formation of capsule
 - D. Quick disappear
 - E. * Slow (during 1,5-3 month) disappear
1998. What is the basic method of treatment of acute pancreatitis:
- A. Diet
 - B. Physical therapy
 - C. Homoeopathic
 - D. Surgical
 - E. * Conservative
1999. What is the basic methods of diagnostics of postnecrotic cysts:
- A. Laparoscopy
 - B. ERCP
 - C. Colonoscopy
 - D. Endoscopy
 - E. * Sonography and CT
2000. What is the best method of examination of pancreatic infiltrate:
- A. Sonography
 - B. X-Ray
 - C. Biochemical blood test
 - D. Palpation
 - E. * Sonography
2001. What is the best resort which is used for pathology of pancreas?
- A. Nemirov
 - B. Truskavets
 - C. Kuyal'nik
 - D. P'yatigorsk
 - E. * Morshin
2002. What is the complications of pseudocyst of pancreas:
- A. Fistula
 - B. Bleeding
 - C. Perforation
 - D. Suppuration
 - E. * All is true
2003. What is the inhibitors of protease:

- A. Trypsinum
 - B. Tocopherolum
 - C. Loroxon
 - D. Tebris
 - E. * Trasilol
2004. What is the inhibitors of protease:
- A. Gramicidine
 - B. Loroxon
 - C. Garamycine
 - D. Motilium
 - E. * Gordox
2005. What is the method of treatment of chronic calculus cholecystitis?
- A. Conservative therapy
 - B. Antispastic drugs
 - C. Lithothripsy
 - D. Cholecystostomy
 - E. * Cholecystectomy
2006. What is the most effective treatment of the non-formed non-complicated cyst:
- A. Cystogastrostomy
 - B. Cystoenteroanastomosis
 - C. A resection of cyst
 - D. External draining of cyst
 - E. * Conservative treatment
2007. What is the most frequent reason of development of mechanical jaundice?
- A. Metastases of tumor into the liver
 - B. Peptic ulcer
 - C. Cancer of head of pancreas
 - D. Stricture of extrahepatic bile ducts
 - E. * Choledocholitis
2008. What is the reason of late complications of acute pancreatitis?
- A. By violation of local blood flow
 - B. Obstruction of pancreatic ducts
 - C. Development of aseptic inflammation
 - D. Enzymes
 - E. * Infection
2009. What localization of ulcer is most characteristic for the patients of elderly and senile age
- A. * cardial department of stomach
 - B. overhead third of gullet
 - C. lower third of gullet
 - D. bulb of duodewnum
 - E. small curvature
2010. What method diagnostics hte ulcerous illness most informing
- A. * esophagogastrroduodenoscopy
 - B. analysis of excrement on the hidden blood
 - C. X-ray
 - D. global analysis of blood
 - E. research of gastric secretion

2011. What method is it orientation possible to define the volume of hemorrhage on at the acute gastroenteric bleeding?
- A. On maintenance red corpuscles, haemoglobin, Ht, thrombocytes
 - B. On blood volume
 - C. * On an arteriotomy, pulse, state of patient
 - D. On a globular volume
 - E. On the level of thrombocytes
2012. What method of examination is most informative at the estimation of pathology of bile ducts?
- A. CT
 - B. Sonography
 - C. transcutaneous transhepatic cholangiography
 - D. intravenous cholangiography
 - E. * ERCP
2013. What method of examination is most informative for diagnostics of calculus cholecystitis?
- A. ERCP
 - B. Endoscopy
 - C. X-Ray
 - D. Laparoscopy
 - E. * Sonography
2014. What operation is indicated at the edematous form of acute pancreatitis:
- A. Marsupialisation
 - B. Abdominisation of pancreas
 - C. Omentopancreatopexy
 - D. Pancreatectomy
 - E. * Operation is not needed
2015. What operation is not performed at pancreatic abscesses and infected necrosis?
- A. Draining of abscess
 - B. Pancreato-necro-sekvestrectomy with laparostomy
 - C. Pancreato-sekvestrectomy
 - D. Pancreato-necro-sekvestrectomy
 - E. * Total pancreatectomy
2016. What operation is performed at localization of the formed pseudocyst in the tail of pancreas:
- A. Cistoenteroanastomosis
 - B. Cistoenterostomy
 - C. Conservative treatment
 - D. External draining of cyst
 - E. * Resection of tail of pancreas
2017. What operation is performed at the pseudocyst of pancreas in III stage usually:
- A. Conservative treatment
 - B. Cistoduodenostomy
 - C. Cystogastrostomy
 - D. External draining of cyst
 - E. * Cistoenterostomy
2018. What pathology is characterized by presence of plenty of hemorrhagic exudates with high ferment activity in the abdominal cavity?

- A. Destructive cholecystitis
 - B. Perforation of ulcer
 - C. Hepatitis
 - D. Cirrhosis of liver
 - E. * Pancreonecrosis
2019. What place does occupy an acute pancreatitis among acute surgical diseases?
- A. It is most widespread
 - B. Second place
 - C. Fifth place
 - D. First place
 - E. * Third place
2020. What preparation does behave to blocker H₂-retseptors?
- A. * tavegil
 - B. obzidan
 - C. hystdol
 - D. cerucal
 - E. oraza
2021. What preparation does behave to blocker of muscarine receptors of coating cages?
- A. cymetidin
 - B. eglonin
 - C. * gastocepini
 - D. etimsiloli
 - E. vinylin
2022. What preparations, except for other properties, own yet and a bacteriostatic effect on *Helicobacter pyloris*
- A. * all are transferred preparations
 - B. Almagel
 - C. Vinylin
 - D. De-nol
 - E. Claritromycin
2023. What procedure is prescribed for patients with plenty of hemorrhagic exudates with high ferment activity in the abdominal cavity?
- A. Conservative treatment
 - B. Computer examination of organs of abdominal cavity
 - C. X-Ray of organs of abdominal cavity
 - D. Sonography of organs of abdominal cavity
 - E. * Laparotomy
2024. What procedure must be performed at the postnecrotic cysts of pancreas:
- A. Omentopancreatopexy
 - B. Pancreatotomy
 - C. Necrectomy
 - D. Pancreatectomy
 - E. * Puncture and external draining of cyst
2025. What products are recommended in the diet of № 1?
- A. * hen in a steam kind
 - B. pancakes
 - C. raw egg-white

- D. bread rye fresh
 - E. acute cheeses
2026. What symptom is typical for a acute pancreatitis?
- A. Rovzing symptom
 - B. Lenander symptom
 - C. Ker symptom
 - D. Pasternacky symptom
 - E. * Kulen symptom
2027. What syndrome is characteristic for hemorrhagic erosive gastritis?
- A. * ulcerous
 - B. hemorrhagic;
 - C. pain;
 - D. all answers are correct;
 - E. all answers are not correct.
2028. What time urgent operations are executed at acute bleeding
- A. * 6 – 12 hours;
 - B. 6 – 10 hours;
 - C. 6 – 8 hours
 - D. 6 – 14 hours;
 - E. 6 – 20 hours
2029. What violation of mineral exchange is characteristic for patients with ulcerous illness of stomach and intestine
- A. hypocalcemia
 - B. * hypokaliemia
 - C. Hyponatremia
 - D. Hypercalcinemia
 - E. hyperkaliemia
2030. When apply Teylor's method at ulcerous illness
- A. * at conservative treatment perforeted ulcers
 - B. at conservative treatment sanguifluous ulcers
 - C. at conservative treatment penetration ulcers
 - D. at conservative treatment malignization ulcers
 - E. at conservative treatment of cicatrical pyloristenosis
2031. When could be intoxication psychosis at acute pancreatitis?
- A. In 2 weeks
 - B. On the 9-11 days
 - C. On the 6-8 days
 - D. On the first day
 - E. * On the 2-3 days
2032. When do patients have late complications of acute pancreatitis?
- A. 1-2 days
 - B. 2-3 days
 - C. 5-6 days
 - D. 3-4 days
 - E. * 10-12 days
2033. Which drug is applied at chronic pancreatitis:

- A. Panthenol.
- B. Pyracetamum;
- C. Pantocrinum;
- D. Papaverin;
- E. * Creon

2034. Which pathology characterized by absence of pulsation of abdominal aorta (Voskresensky symptom):

- A. Acute appendicitis
- B. Acute ileus
- C. Peptic ulcer
- D. Acute cholecystitis
- E. * Acute pancreatitis

2035. Which pathology characterized by appearance of cyanosis of lateral surfaces of abdomen (symptom of Turner):

- A. Acute appendicitis
- B. Acute ileus
- C. Acute cholecystitis
- D. Peptic ulcer
- E. * Acute pancreatitis

2036. Which pathology characterized by appearance of pain in left costal-vertebral area (symptom of Meyo-Robson):

- A. Acute appendicitis
- B. Acute ileus
- C. Acute cholecystitis
- D. Peptic ulcer
- E. * Acute pancreatitis

2037. Which pathology characterized by violet spots on the skin and body:

- A. Acute appendicitis
- B. Acute ileus
- C. Peptic ulcer
- D. Acute cholecystitis
- E. * Acute pancreatitis

2038. A frequent liquid stool is the first sign of:

- A. haemorrhoids
- B. Fissures of anus
- C. Proctosigmoiditis
- D. * UUC
- E. All of answers are correct

2039. A method of choice at surgical treatment of unspecific ulcerative colitis

- A. * proctocolectomy
- B. hemicolectomy
- C. resection of colon
- D. colectomy
- E. application of colostomy.

2040. A patient 40 years old, suffered ulcerous diseases of stomach. Last 2 days the pain became less intensive, but weakness and dizziness were appeared. Rose from a bed and lost consciousness. Pale. There are insignificant pains in epigastrium. It is

- A. Combination perforation with bleeding
 - B. Perforation
 - C. Malignization of ulcer
 - D. Stenosis of ulcer
 - E. * Gastroenteric bleeding
2041. A patient after the electroscission of polypus of sigmoid bowel has bleeding. What is tactic?
- A. * it is performed hemostatic therapy
 - B. it is performed operative treatment
 - C. concervative treatment
 - D. laparotomy
 - E. laparoscopy
2042. A patient after the electroscission of polypus of sigmoid bowel has stomach-aches. What complication can be?
- A. * perforation
 - B. bleeding
 - C. malignancy
 - D. toxic dilatation
 - E. penetration
2043. A patient with 10-years anamnesis of unspecific ulcerative colitis has periodic swelling of abdomen, feeling of the incomplete emptying, worsening of the general state. On irrigography is absent haustration with circular narrowing in sigmoid bowel. What complication patient has?
- A. * A regeneration to the cancer
 - B. Toxic dilatation
 - C. Bleeding
 - D. Perforation
 - E. Nothing
2044. A patient with 10-years anamnesis of unspecific ulcerative colitis has periodic swelling of abdomen, feeling of the incomplete emptying, worsening of the general state. On irrigography is absent haustration with circular narrowing in sigmoid bowel. What operation is prescribed?
- A. * Colproctectomy
 - B. Resection of sigmoid bowel
 - C. Left-side hemicolectomy
 - D. Sigmoidostomy
 - E. Right-side hemicolectomy
2045. A presence of mucus and pus in stool is characteristic for:
- A. Proctosigmoiditis
 - B. Cancer of rectum
 - C. UUC
 - D. All of answers are wrong
 - E. * All of answers are correct
2046. Absolute indication for the surgical treatment of unspecific ulcerative colitis
- A. * bleeding, perforation, toxic dilatation
 - B. absence of effect from conservative treatment
 - C. frequent diarrhea, loss of weight
 - D. a pain syndrome
 - E. adhesion
2047. Absolute indication to operative treatment the ulcerous illness is

- A. heavy pain syndrome
 - B. * perforation of ulcer
 - C. relapses more than 2 one time per a year
 - D. ulcerous anamnesis more than 10 years
 - E. giant ulcers
2048. Absolute indication to operative treatment the ulcerous illness is
- A. * voluminous bleeding
 - B. callous ulcers
 - C. relapses more than 2 one time per a year
 - D. ulcerous anamnesis more than 10 years
 - E. heavy pain syndrome
2049. Absolute indication to operative treatment the ulcerous illness is
- A. ulcerous anamnesis more than 10 years
 - B. * bleeding what do not stopped with conservative
 - C. perforation ulcer in anamnesis
 - D. heavy pain syndrome
 - E. relapses more than 3 times per a year
2050. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. ulcerous anamnesis more than 10 years
 - C. relapse ulcer after the resection of stomach
 - D. relapses more than 3 times per a year
 - E. * cicatrical-ulcerous stenosis of pylorus
2051. Absolute indication to operative treatment the ulcerous illness is
- A. relapses more than 2 one time per a year
 - B. * malignization ulcers
 - C. ulcerous anamnesis more than 10 years
 - D. heavy pain syndrome, proof heartburn
 - E. relapse ulcer after vagotomy
2052. Absolute sign of unstable hemostasis
- A. * profluvium blood from a vessel;
 - B. absence blood in a stomach and bulb of duodenum;
 - C. presence light blood and faltungs of blood in a stomach;
 - D. all answers are correct;
 - E. all answers are not correct
2053. After what operation at ulcerous illness the natural arcade of meal is saved on a digestive tract
- A. Valter-Braun's gastroenterostomy
 - B. not saved after any operation
 - C. resection by Bilrot II
 - D. * resection by Bil'rot I
 - E. saved after all transferred operations
2054. After what operation innervation of pyloric department of stomach is saved
- A. * selective vagotomy
 - B. barrel vagotomy
 - C. selective proximal vagotomy
 - D. at all transferred

- E. not saved after all operations
2055. An anal itch is a sign of:
- A. Insufficiency of sphincter of anus
 - B. Mycotic lesion of skin of coccyx
 - C. The hidden diabetes
 - D. Intestinal worm invasion
 - E. * All of answers are correct
2056. At beginning bleeding from an ulcer
- A. * pain diminishes
 - B. pain increases
 - C. there is knife-like pain
 - D. character of pain does not change
 - E. girdle pain
2057. At bleeding emergency operative interferences are executed
- A. * to 3 hours
 - B. to 1,5 hour
 - C. to 6 hours
 - D. to 8 hours
 - E. 6 – 12 hours
2058. At colonoscopy for a patient 60 years old was remoted the polypus of sigmoid bowel in the distance 35 cm from anus. Histologically was found a microinvasive cancer an it apex. On it basis it is not found the cancer's cell. What is tactic of doctor?
- A. * Repeated colonoscopies every 3 months
 - B. Radial therapy
 - C. The resection of sigmoid bowel
 - D. Chemotherapy
 - E. Nothing
2059. At Crohn disease is damaged
- A. * all parts of gastrointestinal tract
 - B. only small intestine
 - C. only colon
 - D. only rectum
 - E. only sigmoid bowel
2060. At III stage blood loss at the bleeding ulcer the patient loses
- A. over 1000 ml blood
 - B. * over 2000 ml blood
 - C. over 500 ml blood
 - D. over 2500 ml blood
 - E. over 1500 ml blood
2061. At III stage blood loss at the bleeding ulcer the patient loses
- A. more than 25 % blood volume
 - B. * more than 30 % blood volume
 - C. more than 20 % blood volume
 - D. more than 15 % blood volume
 - E. more than 35 % blood volume
2062. At the duodenum ulceroperation of choice is

- A. * resection by Bilrot I
 - B. resection by Bilrot II
 - C. resection of duodenum
 - D. selective proximal vagotomy
 - E. sewing up of ulcer
2063. At the gastroenteric bleeding the middle degree of blood loss is diagnosed at next indexes
- A. Hb below 80 g/l
 - B. * Hb 80-100 g/l
 - C. red corpuscles below $2,5 \cdot 10^{12}/l$
 - D. red corpuscles of $3,5-4,0 \cdot 10^{12}/l$
 - E. Ht below 25%
2064. At the III item of activity hemostasis and III stage blood loss from the I – III stage blood loss indicated
- A. * urgent operations (6 – 12 hours);
 - B. emergency operations (to 3 hours);
 - C. exigent operations (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
2065. At the V item activity of hemostasis and at the recurrent bleeding of the I – III item of blood loss indicated
- A. * emergency operations (to 3 hours);
 - B. urgent operations (6 – 12 hours);
 - C. exigent (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
2066. At ulcerous illness can a bleeding source be
- A. artery;
 - B. veins;
 - C. shallow vessels and ulcers;
 - D. all answers are not correct.
 - E. * all answers are correct
2067. At what degrees of unspecific ulcerative colitis is indicated hormonal preparations
- A. * heavy degrees
 - B. easy degrees
 - C. middle degrees
 - D. to chronic
 - E. chronic relapse
2068. At what disease could be histologically unspecific granuloma
- A. * Crohn disease
 - B. unspecific ulcerative colitis
 - C. cancer of rectum
 - D. poliposis
 - E. diverticulosis
2069. Bergman's sign is characteristic for
- A. * bleeding ulcer
 - B. for cicatricial-ulcerous pylorostenosis
 - C. perforated ulcers

- D. penetratration ulcers
 - E. malignization ulcers
2070. Berhtein's sing characteristic for
- A. * perforeted ulcers
 - B. bleeding ulcer
 - C. penetratrated ulcers
 - D. malignizated ulcers
 - E. for cicatrical-ulcerous pylorostenosis
2071. Bleeding ulcer, complicated blood loss III stage degrees, requires
- A. * blood and its components transfusions
 - B. transfusion of salt solutions
 - C. transfusion of colloid solutions
 - D. transfusion of salt and colloid solutions
 - E. infusion therapy does not need
2072. Blood loos I stage characterized such indexes
- A. Ht 48-44, Hb 120
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 31-23, Hb 80
 - D. * Ht 38-32, Hb 100
 - E. Ht 44-40, Hb 110 /?
2073. Blood loos II stage characterized
- A. * Ht 23 and below, Hb 50 and below
 - B. Ht 31-23, Hb 80
 - C. Ht 44-40, Hb 110
 - D. Ht 48-44, Hb 120
 - E. Ht 48-44, Hb 120
2074. Blood loos III stage characterized a degree such indexes
- A. * Ht 31-23, Hb 80
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 38-32, Hb 100
 - D. Ht 44-40, Hb 110
 - E. Ht 48-44, Hb 120
2075. Characteristic complications of unspecific ulcerative colitis
- A. * bleeding, perforation, toxic dilatation of bowels
 - B. pancreatitis, cholecystitis
 - C. adhesion
 - D. perforation, penetration
 - E. peritonitis
2076. Classification of unspecific ulcerative colitis by its clinical management
- A. * acute, fulminating, chronic continuous and relapse
 - B. proctitis, proctosygmoiditis
 - C. left-side and total colitis
 - D. easy, middle, heavy
 - E. easy, heavy
2077. Classification of unspecific ulcerative colitis by its distribution
- A. * proctitis, proctosygmoiditis, left-side and total colitis

- B. acute, quick
 - C. chronic continuous and relapse
 - D. left-side and total colitis
 - E. easy, middle, heavy
2078. Clinical symptoms of the unspecific ulcerative colitis
- A. * pain, diarrhea, loss of weight
 - B. icterus, hydroperitoneum
 - C. increasing of liver and spleen
 - D. pain, obesity
 - E. pain, icterus, hydroperitoneum
2079. De-Cerven's sign is characteristic for
- A. bleeding ulcer
 - B. * perforated ulcers
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorostenosis
2080. Diet at bleeding gastric and duodenum ulcers
- A. * Meulengracht's
 - B. 1 by Pevznerom
 - C. 5 by Pevznerom
 - D. 15 by Pevznerom
 - E. 7 by Pevznerom
2081. Disappearance or diminishing the pain with beginning of bleeding from an ulcer is
- A. * Bergman's sign
 - B. Spazarskiy's sign
 - C. Mendel's sign
 - D. De Keven's sign
 - E. Eleker's sign
2082. Duration the period of primary shock at a perforated ulcer
- A. * 3-6 hours
 - B. 6-12 hours
 - C. 1-3 hours
 - D. 12-24 hours
 - E. 24-36 hours
2083. During rectoscopy is found the endoscopic symptom of "roadway". What disease?
- A. Unspecific ulcerative colitis
 - B. * Crohn disease of rectum
 - C. Dysentery
 - D. Salmonellosis
 - E. Syndrome of irritation of colon
2084. Eleker's sign is characteristic for
- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorostenosis

2085. Esophagogastroduodenoscopy can find out next changes in a stomach, except for
- tumours
 - ulcers
 - bleeding polypuses
 - erosions
 - * changes of evacuation function
2086. Features of surgical treatment of anaerobic paraproctitis
- * opening by wide cuts
 - ligature method
 - operation of Gabriel
 - an operation by Rizhik-Bobroviy
 - by Milligan-Morgan and Gabriel.
2087. For bleeding ulcer characteristic sign is
- * pain in an epigastrium;
 - knife-like pain;
 - signs irritation of peritoneum;
 - presence fresh blood in incandescence
 - melena;
2088. For bleeding ulcer characteristically
- * melena
 - tension the muscles of front abdominal wall
 - Spazarskiy's sing
 - sickliness the back vault of vagina
 - irradiation pain in a shoulder or shoulder-blade
2089. For motion of disease ulcerous illness of middle weight characteristically
- development of complications
 - * relapses 1-2 times per a year
 - 4 and anymore relapses on a year
 - 5 and more relapses are on a year
 - 3 and anymore relapses on a year
2090. For perforeted ulcer characteristically
- * tension the muscles of front abdominal wall
 - melena
 - vomiting by coffee-grounds
 - high intestinal impassability
 - vomiting stagnant gastric maintenance
2091. For pneumoperitoneum is characteristic symptom
- * Zhober's;
 - Khelatid's;
 - Podlag's;
 - Vigats's;
 - Udin's.
2092. For the heavy flow of ulcerous illness characteristically
- 2 and anymore relapses on a year
 - * 3 and anymore relapses on a year
 - 4 and anymore relapses on a year
 - 5 and more relapses are on a year

- E. 6 and more relapses are on a year
2093. For the heavy flow of ulcerous illness characteristically
- A. * development of complications
 - B. seasonal exacerbation more not frequent 1-2 times per a year
 - C. 1-2 relapse on a year
 - D. liquid, but protracted exacerbation
 - E. exacerbation duration more than 10 days
2094. For what disease characteristic symptom of "water-pipe"?
- A. * Unspecific ulcerative colitis.
 - B. Crohn disease.
 - C. Pseudopoliposis.
 - D. Diverticulosis.
 - E. Spastic colitis.
2095. For what disease is characteristic symptom of "roadway"?
- A. * Crohn disease.
 - B. Amebioz.
 - C. Spastic colitis.
 - D. Cancer of large intestine.
 - E. Unspecific ulcerative colitis.
2096. For which diseases of large intestine characteristic symptom of the "shot target"
- A. * unspecific ulcerative colitis
 - B. diverticulosis
 - C. poliposis
 - D. cancer
 - E. Crohn disease
2097. From what department degestive tract developmentp more frequent than all the bleeding at the Mallory-Weiss syndrome
- A. gastric fundus
 - B. * cardial pert;
 - C. pyloric department;
 - D. from duodenal;
 - E. from a thick intestine
2098. From what part of gastrointestinal tract is bleeding when presence of cherry-colour blood in the stool
- A. * colon
 - B. stomach and duodenum
 - C. rectum
 - D. duodenum
 - E. small intestine
2099. From what part of intestine is most often begins unspecific ulcerative colitis?
- A. * From the rectum.
 - B. From the ascending part of colon.
 - C. From the transverse part of colon.
 - D. From the descent part of colon.
 - E. From the terminal part of small intestine.
2100. From what tissue anal papilla are formed from?

- A. From epithelial tissue
 - B. * From connective tissue
 - C. From lymphoid tissue
 - D. From muscular tissue
 - E. From mucus
2101. Giant ulcer is an ulcer measuring
- A. over 4,5 cm
 - B. * over 3 cm
 - C. over 4 cm
 - D. over 5 cm
 - E. over 3,5 cm
2102. Haemorrhoid's nodes do not fall out at
- A. * I stage
 - B. II stage
 - C. III stage
 - D. External nodes
 - E. Internal nodes
2103. Haemorrhoid's nodes fall out and not replaced
- A. * III stage
 - B. I stage
 - C. II stage
 - D. External nodes
 - E. Internal nodes
2104. Haemorrhoid's nodes fall out during defecation and replaced
- A. * II stage
 - B. I stage
 - C. III stage
 - D. External nodes
 - E. Internal nodes
2105. Haemorrhoidectomy is complicated by cicatricial stricture of rectum. What next operation is indicated?
- A. * dosed sphincterotomy with sewing mucus of rectum to the perianal skin
 - B. anal bougienage
 - C. dosed sphincterotomy
 - D. hemorrhoidectomy
 - E. colostomy
2106. Haemorrhoids complicated by bleeding is indication for
- A. * urgent operation
 - B. planned operation
 - C. conservative therapy
 - D. physiotherapeutic procedure
 - E. therapy not performed
2107. Haemorrhoids complicated by thrombosis is indication for
- A. * urgent operation
 - B. planned operation
 - C. conservative therapy
 - D. physiotherapeutic procedure

- E. therapy not performed
2108. Hemobilia is
- A. * all answers are correct;
 - B. bleeding the bilious ways and liver;
 - C. bleeding the general bilious channel;
 - D. bloody clot in the big duodenal papilla;
 - E. all answers are not correct.
2109. How many physiology flexures has rectum?
- A. 1
 - B. * 2
 - C. 3
 - D. 4
 - E. 5
2110. Hyperbaric oxygenation in a postoperative period is used at:
- A. * Anaerobic paraproctitis
 - B. To the anal fissure
 - C. Epithelial coccygeal
 - D. Haemorrhoids
 - E. Cancer of rectum
2111. In the perianal area patient has the slight swelling, red skins, soft infiltrate. What is the diagnosis?
- A. * Acute paraproctitis
 - B. Anal fissure
 - C. Haemorrhoids
 - D. Cancer of rectum
 - E. Proctopolypus
2112. In what amount of physiologic solution does dissolve medicines for medical micro-enemas?
- A. * 80 ml.
 - B. 200 ml.
 - C. 250 ml.
 - D. 300 ml
 - E. 400 ml
2113. In what area of stomach practically never is not origin of ulcers, or it is extraordinarily rarely?
- A. small curvature of stomach;
 - B. back wall of stomach, nearer to small curvature;
 - C. large curvature of stomach
 - D. * cardiac part of stomach;
 - E. pylorus.
2114. In what vein is a venous outflow carried out in from a stomach?
- A. * V. Portae;
 - B. V. odd;
 - C. V. pair;
 - D. V. overhead hollow;
 - E. V. lower hollow;
2115. Indication to the operation of haemorrhoidectomy is

- A. * repeated thrombosis of haemorrhoids nodes
 - B. portal hypertension
 - C. second stage of non-complicated haemorrhoids
 - D. first stage of non-complicated haemorrhoids
 - E. itch
2116. Indication to the operation of haemorrhoidectomy is
- A. * thrombosis of haemorrhoids nodes
 - B. portal hypertension
 - C. pain
 - D. itch
 - E. discomfort
2117. Large ulcer is an ulcer measuring
- A. 1-4 cm
 - B. 1-3 cm
 - C. 3-5 cm
 - D. 2- 6 cm
 - E. * 2-3 cm
2118. Little ulcer it is an ulcer measuring
- A. * to 0,5 cm
 - B. 0,5-1 cm
 - C. to 1,0 cm
 - D. 3 to 1,5 cm
 - E. 0,5-1,5 cm
2119. Mark the disease of colon, which characterised by such complications as bleeding, formation of stricture, perforation, toxic dilatation, malignancy:
- A. Haemorrhoids
 - B. Fissure
 - C. Polipus
 - D. * Unspecific ulcerative colitis
 - E. Paraproctitis
2120. Meets the most frequent localization bleeding the digestive tract is
- A. gullet;
 - B. stomach;
 - C. rectum;
 - D. * duodenum;
 - E. colon
2121. Melena is
- A. black designed chair
 - B. * black liquid tarry chair
 - C. a discoloured liquid excrement
 - D. foamy stinking emptying of black
 - E. an excrement designed veined blood
2122. Melena is a characteristic sign
- A. * bleeding ulcer
 - B. for cicatrical-ulcerous pylorus stenosis
 - C. perforated ulcers
 - D. penetration ulcers

- E. malignization ulcers
2123. Method of surgical treatment of acute submucous proctitis
- A. * by Rizhik-Bobroviy
 - B. opening of abscess by a radial cut
 - C. ligature method
 - D. Operation of Rizhikh-1.
 - E. by Milligan-Morgan.
2124. Method of surgical treatment of anal fissure
- A. * cutting of fissure
 - B. by Milligan-Morgan.
 - C. suturing of fissure
 - D. by Kyumel-Zerenin.
 - E. by Kenyu-Milse.
2125. Method of surgical treatment of haemorrhoids
- A. * by Milligan-Morgan.
 - B. by Bebkok
 - C. by Narat
 - D. by Gabriel.
 - E. Operation of Blinnichev.
2126. Most informing method at a bleeding ulcer
- A. survey sciagraphy the organs of abdominal region
 - B. * EFGDS
 - C. sciagraphy the stomach with contrasting
 - D. Sonography
 - E. Laparoscopy
2127. Name classic complications of ulcerous illness
- A. bleeding, pylorostenosis, second pancreatitis, malignization, perforation
 - B. * perforation, penetration, bleeding, pylorostenosis, malignization
 - C. malignization, pylorostenosis, penetration, anaemia, perforation
 - D. bleeding, perforation, second pancreatitis, anaemia, malignization
 - E. perforation, peritonitis, pancreatitis, bleeding, penetration
2128. On irrigography is found the symptoms of «water-pipe», «shot through target». What is diagnosis?
- A. * Unspecific ulcerative colitis
 - B. Crohn disease
 - C. Dysentery
 - D. Salmonellosis
 - E. Food toxicoinfection
2129. Operating access at operations on a stomach
- A. * Upper-middle laparotomy
 - B. Lower-middle laparotomy
 - C. Pararectum access
 - D. Volokovich-Dyakonov's access
 - E. Pfanenhtil's access
2130. Operation which performed after the cutting of fissure of rectum
- A. * by Gabriel

- B. by Milligan-Morgan.
 - C. sphincterotomy
 - D. by Kyumel-Zerenin.
 - E. by Kenyu-Miles.
2131. Patient which the gastroenteric bleeding in house is necessary
- A. * To send a patient in surgical permanent establishment
 - B. To appoint rest, enter Cacl, vicasol
 - C. To wash a stomach, appoint a cold, rest of supervision
 - D. To send a patient in a therapeutic gastroenterology separation
 - E. A right answer absents
2132. Patient 27 years old has stomach-ache, liquid stool up to 10 times per days with mucus and blood, weakness, weight lost. On the irrigigraphy is narrowing of transvers colon. What diagnosis?
- A. Dysentery.
 - B. Polypus of small intestine.
 - C. * Cancer of transvers colon.
 - D. Spastic colitis.
 - E. Unspecific ulcerative colitis
2133. Patient 50 years old has permanent pain in the anus, frequent defecation with blood, lost of appetite, weight lost, weakness. What examination is prescribed?
- A. * A biopsy with histological examination
 - B. Radio-active scan
 - C. Selective angiography
 - D. Doplerography
 - E. Sonography
2134. Patient 59 years old has suspicion of the tumour of ascending part of colon. What method of examination is the best?
- A. * A colonoscopy with a biopsy
 - B. Irrigography
 - C. Survey sciagraphy
 - D. Sonography
 - E. Endoscopy
2135. Patient 72 years old has acute pain in the left half of abdomeb, nausea, delay of stool and gases. He is ill 6 hours. No mucus and blood in stool, not weight lost . Pulse 84 per 1 min. Peristaltic noises is increased periodically. On the X-Ray of organs of abdominal region is present the Kloyber's cup in the left half of abdomen. What diagnosis ?
- A. * Invagination of sygmoid bowel
 - B. Crohn disease
 - C. Poliposis
 - D. Unspecific ulcerative colitis
 - E. Diverticulosis
2136. Patient during the act of defecation has paine in anal channel, red blood in the stool. What disease?
- A. * Anal fissure
 - B. Haemorrhoids
 - C. Acute paraproctitis
 - D. Cancer of rectum
 - E. Proctopolypus

2137. Patient has poliposis of right half of colon. What is treatment?
- A. * right hemicolectomy
 - B. conservative treatment
 - C. stoma
 - D. by Milligan-Morgan.
 - E. by Gabriel.
2138. Patient has a blood in the first portions of stool. What disease is possible?
- A. * Cancer of rectum.
 - B. Haemorrhoids.
 - C. Fissure.
 - D. Paraproctitis.
 - E. Fistula.
2139. Patient has a general weakness, presence of dark blood in the stool. At a rectoscopy on 11 cm from anus is found the circular narrowing of rectum. What diagnosis?
- A. * Cancer of rectum
 - B. Proctopolypus
 - C. Acute paraproctitis
 - D. Chronic paraproctitis
 - E. Acute proctitis
2140. Patient has a red blood at the end of defecation. What disease is possible?
- A. * Haemorrhoids and fissure of mucus of rectum.
 - B. Gastric and duodenal ulcers.
 - C. Cancer of rectum.
 - D. Paraproctitis.
 - E. Fistula.
2141. Patient has anal fissure of mucus of rectum with periodic pains. Pregnancy 16 weeks. Tactic of surgeon?
- A. * an operation - cutting of fissure after birth of child
 - B. an operation by Milligan-Morgan
 - C. an operation by Gabriel
 - D. cutting of fissure
 - E. an operation by Kenu-Miles
2142. Patient has anterior mucosal prolapse of rectum of the III stage and complete prolapse of uterus. What operation is indicated?
- A. * By Kumel-Zerenin, amputation of uterus
 - B. by Kenu-Miles
 - C. by Tartu
 - D. by Rizhikh-1
 - E. by Milligan-Morgan
2143. Patient has bleeding from a colon as a result of complication of unspecific ulcerative colitis. What operation is indicated?
- A. * proctocolectomy
 - B. suturing of bleeding area of bowel
 - C. resection of bowel
 - D. colectomy
 - E. colostomy

2144. Patient has cicatricial narrowing of sigmoid bowel with intestinal obstruction as complication of unspecific ulcerative colitis. What operation is indicated?
- A. * proctocolectomy
 - B. resection of the narrowed area of bowel
 - C. colectomy
 - D. colostomy
 - E. Operation by Kenyu-Miles.
2145. Patient has diarrhea up to 25-30 times per days with blood, has weight lost, general weakness, periodic stomach-ache. He is ill during 1,5 month. What diagnosis?
- A. * Unspecific ulcerative colitis
 - B. colitis
 - C. Pseudopoliposis
 - D. Diverticulosis
 - E. Spastic colitis
2146. Patient has intersphincteric fistula and external haemorrhoids. What operation is performed?
- A. * By Milligan-Morgan and Gabriel.
 - B. By Milligan-Morgan.
 - C. By Gabriel.
 - D. Operation of Blinnichev.
 - E. Operation of Rizhikh-1.
2147. Patient has long-term ulcer of rectum. In anamnesis white plague. What is previous diagnosis?
- A. * tuberculosis of rectum
 - B. haemorrhoids
 - C. paraproctitis
 - D. fistula
 - E. fissure of rectum
2148. Patient has melena. What is the source of bleeding?
- A. * Stomach and duodenum.
 - B. Rectum.
 - C. Colon.
 - D. Small intestine.
 - E. Sigmoid bowel.
2149. Patient has paraproctitis and fistula in pararectal area. Also it is present fruzi of actinomicete. What diagnosis?
- A. * actinomicosis
 - B. haemorrhoids
 - C. paraproctitis
 - D. fistula
 - E. fissure of rectum
2150. Patient has perforation of colon as complication of unspecific ulcerative colitis. What operation is indicated
- A. * proctocolectomy
 - B. suturing of the perforative hole
 - C. resection of area of bowel
 - D. colectomy
 - E. colostomy

2151. Patient has poliposis of left half of colon. What is treatment?
- A. * left-side hemicolectomy
 - B. conservative treatment
 - C. stoma
 - D. by Milligan-Morgan.
 - E. by Gabriel.
2152. Patient has polypus of sigmoid colon with signs of malignancy. What treatment?
- A. * resection of area of bowel with polypus
 - B. electroscission
 - C. cutting of polypus
 - D. criodestruction
 - E. conservative
2153. Patient has polypus on wide leg on 15 sm from anus. What treatment?
- A. * removal of polypus by laparotomy, rectotomy
 - B. electroscission
 - C. conservative treatment
 - D. ligating
 - E. criodestruction
2154. Patient has proctopolypus on 15 sm from anus with the signs of mamalignancy
- A. * anterior resection of rectum
 - B. electroscission
 - C. cutting of polypus
 - D. criodestruction
 - E. conservative
2155. Patient has small sizes proctopolypus in sygmoid bowel and pregnancy 8 weeks. Tactic of surgeon?
- A. * it is removing polypus after birth of child
 - B. an operation by Milligan-Morgan
 - C. an operation by Gabriel
 - D. cutting of polypus during pregnancy
 - E. an operation by By Kenu-Miles
2156. Patient has swelling from an anal channel during the act of defecation, without paine, with fresh blood after defecation. Previous diagnosis?
- A. Anal fissure
 - B. * Haemorrhoids
 - C. Acute paraproctitis
 - D. Cancer of rectum
 - E. Proctopolypus
2157. Patient has the combined haemorrhoids and pregnancy 8 weeks. Tactic of surgeons?
- A. * it is performed operative treatment after birth of child
 - B. an operation by Gabriel
 - C. an operation by Milligan-Morgan
 - D. by Rizhikh-1
 - E. by Kenu-Miles
2158. Patient has the combined haemorrhoids with bleeding and pregnancy 9 weeks. Tactic of surgeon?
- A. * an operation by Milligan-Morgan

- B. an operation by Gabriel
 - C. it is performed operative treatment after birth of child
 - D. by Rizhikh-1
 - E. by Kenu-Miles
2159. Patient has the III stage anterior mucosal prolapse of rectum. What operation is indicated?
- A. * by Kyumel-Zerenin
 - B. by Kenyu-Miles
 - C. by Milligan-Morgan
 - D. by Gabriel
 - E. by Rizhikh-1
2160. Patient has toxic dilatation as complication of unspecific ulcerative colitis. What operation is indicated?
- A. * proctocolectomy
 - B. resection of dilatated area of colon
 - C. colectomy
 - D. colostomy
 - E. an operation by Kenu-Miles
2161. Patient has ulcer of rectum by duration near two months. The reaction of Wassermann is positive. Previous diagnosis
- A. * venereal lymphogranuloma
 - B. haemorrhoids
 - C. paraproctitis
 - D. fistula
 - E. fissure of rectum
2162. Patients with haemorrhoids has blood in the stool
- A. * during defecation
 - B. before defecation
 - C. after defecation
 - D. constantly
 - E. never
2163. Presence of blood in the stool is characteristically for:
- A. haemorrhoids
 - B. UUC
 - C. Cancer of colon
 - D. Fissures of anus
 - E. * All of answers are correct
2164. Radical operation at a bleeding gastric ulcer and duodenum consists in
- A. sewing vessels on a draught;
 - B. * vagotomy or resection the stomach;
 - C. sewing vessels in an ulcer;
 - D. gastroenteroanastomosis;
 - E. all answers are faithful
2165. Reasons of origin of fissures of rectum
- A. * constipations, diarrhoea
 - B. cancer of rectum
 - C. portal hypertension
 - D. ulcerous disease

- E. varicose disease
2166. Relative absolute indication to operative treatment ulcerous illness is
- A. * penetration of ulcer
 - B. ulcerous anamnesis more than 15 years
 - C. malignization ulcers
 - D. perforation of ulcer
 - E. relapses more than 3 times per a year
2167. Resection of stomach by Bilrot II belongs to
- A. * radical operation
 - B. palliative operation
 - C. draining operations
 - D. organ protect operation
 - E. does not belong to any group
2168. Roentgenological signs of unspecific ulcerative colitis
- A. * symptom of "water-pipe"
 - B. symptom of "niche"
 - C. defect of filling
 - D. symptom of «roadway»
 - E. bowls of Kloyber
2169. Selective proximal vagotomy belongs to
- A. palliative
 - B. draining
 - C. * organ protect operation
 - D. resection
 - E. does not belong to any group
2170. Signs of stable hemostasis
- A. * absence blood in a stomach and duodenum bulb;
 - B. presence the light blood and faltungs of blood in a stomach;
 - C. profluvium blood from a vessel;
 - D. all answers correct;
 - E. all answers are not correct
2171. Signs of unstable hemostasis
- A. * the pulsation of vessel is determined;
 - B. the bottom ulcer is covered a fibrin;
 - C. profluvium blood from a vessel;
 - D. all answers are correct;
 - E. all answers are not correct.
2172. Small amount of blood in stool could has patients with:
- A. * Poliposis
 - B. Colitis
 - C. Pancreatitis
 - D. Peptic ulcer disease
 - E. Appendicitis
2173. Solution of atropine sulfate is used, before operation with a purpose
- A. * of block of peripheral M-cholinoreceptors
 - B. providing of the adequate anaesthetizing

- C. increase of vagus activity
 - D. increasing of frequency of pulse
 - E. decreasing of frequency of pulse
2174. Surgical treatment by the method of cutting of fistula of rectum with cutting of skin and subcutaneous tissue in the type of triangle
- A. * for Gabriel
 - B. for Rizhik-Bobroviy
 - C. ligature method
 - D. by Milligan-Morgan.
 - E. Operation of Rizhikh-1.
2175. Surgical treatment of paraproctitis by the method of desection of fistula of rectum with cutting of skin and mucus in the type of triangle
- A. * by Rizhik-Bobrov
 - B. by Gabriel
 - C. ligature method
 - D. by Milligan-Morgan.
 - E. Operation of Rizhikh-1.
2176. The medicinal “constipation” is used at operations
- A. * on a rectum
 - B. on a small intestine
 - C. on a liver
 - D. on a stomach
 - E. on a duodenum
2177. The nosotropic mechanisms bleedingness at ulcerous illness is
- A. * all answers are correct.
 - B. permanent hyperemia all system of stomach
 - C. different degree dystrophy of superficial layers the mucus shell
 - D. accumulation the central mucopolysaccharides
 - E. hypoplastic, dystrophic processes
2178. The secretory function stomach is carried out the next membrane of stomach
- A. * mucous membrane
 - B. internal muscular layer
 - C. serosal
 - D. mucous submembrane
 - E. external layer
2179. To absolute indication to operative interference at ulcerous illness does not belong
- A. * scarry-ulcerous stenosis
 - B. perforation of ulcer
 - C. profuse bleeding
 - D. diameter ulcer a more than 3 cm
 - E. bleeding what does not stopped with conservative
2180. To the gastric – intestinal bleeding of un ulcerous etiology belong
- A. * Mallory-Weiss syndrome;
 - B. hemorrhagic erosive gastritis;
 - C. diseases by Randyu – Oslera – Vebera;
 - D. Menetrie's sing;
 - E. all answers are correct.

2181. Udin's sign at a perforated ulcer is
- * feeling at palpation show the gases which penetrate through the perforated opening
 - dulling perforated sound in the lateral departments of stomach
 - disappearance of hepatic dullness
 - irradiation pain in a shoulder or shoulder-blade
 - sickliness the back vault of vagina
2182. Vomiting coffee-grounds is a characteristic sign
- * bleeding ulcer
 - penetrative ulcers
 - perforated ulcers
 - malignized ulcers
 - for cicatrical-ulcerous pylorus stenosis
2183. Vomiting what arose up in 4-6 hours after eating characteristic for
- chronic alcoholic gastritis
 - cancer and ulcers of cardia
 - * pylorus ulcers
 - achalasia of gullet
 - ulcer and cancer the body of stomach
2184. What colouring of chair is most characteristic for bleeding from the ulcer of stomach and duodnum?
- * Tarry excrement
 - Presence on the formed excrement of strokes of red blood
 - Littlechanged blood in an excrement
 - Excrement of the raspberry colouring with the admixtures of mucus
 - Acholic excrement
2185. What complication of unspecific ulcerative colitis is indication to urgent surgery?
- Malignizaciya
 - Bleeding
 - Acute toxic dilatation
 - * Perforation
 - Diarrhea
2186. What complication the ulcerous illness of stomach is most characteristically for the patients of elderly and senile age
- perforation
 - perforation + bleeding
 - pylorus stenosis
 - malignization + penetration
 - * bleeding
2187. What disease is damage the superficial layer of wall of bowel
- * unspecific ulcerative colitis
 - Crohn disease
 - diverticulosis
 - poliposis
 - haemorrhoids
2188. What does mean a term "haemorrhoids"?
- Varicose enlargement of haemorrhoidal veins

- B. Spasm of anal sphincter
 - C. * Bleeding
 - D. Inflammation of paraperctal tissue
 - E. Inflammation of anal channel
2189. What does subserve to development of haemorrhoidal thrombosis?
- A. Constipation
 - B. Diarrhea
 - C. * Spasm of sphincter
 - D. Criptitis
 - E. Papillitis
2190. What drug has purgative action?
- A. * Fenolftalein.
 - B. Aspirine.
 - C. Ftalasol.
 - D. Proserin.
 - E. Biphicol.
2191. What drug is decreased frequency of defecation?
- A. * Immodium.
 - B. Kofeol.
 - C. Karbolen.
 - D. Sulfate of magnesium.
 - E. Prozerin.
2192. What drug is used for fistulography?
- A. * Iodlipol.
 - B. Bilignost.
 - C. Verografin.
 - D. Sulfate of barium.
 - E. Methylene bluing.
2193. What drug is used for irrihography?
- A. * Sulfate of barium.
 - B. Cardiotrast.
 - C. Bilignost.
 - D. Iodlipol.
 - E. Methylene.
2194. What drugs is used to decrease meteorism?
- A. * Espumisan.
 - B. Norsulfazolum.
 - C. Vaseline oil.
 - D. Sulfate of magnesium.
 - E. Prozerin.
2195. What enema is used at intestinal obstruction?
- A. * Siphon enema.
 - B. Cleansing.
 - C. Microenema.
 - D. Purgative.
 - E. Does not used.

2196. What external signs are characteristic for the profuse bleeding from a gastric ulcer?
- Vomiting by the littlechanged blood, excrement of the raspberry colouring
 - * Vomiting by the littlechanged blood, tarry darkly-cherry chair
 - Vomiting by a complete mouth by dark blood with clots, black formed excrement
 - Vomiting on the type of "coffee-grounds", presence on the formed incandescence of strokes of red blood
 - Tarry darkly-cherry chair
2197. What form of unspecific ulcerative colitis is most dangerous?
- * Fulminating.
 - Acute.
 - Chronic recurrent.
 - Chronic continuous.
 - Recurrent.
2198. What from preparations has the expressed bacteriostatic action on Helicobacter pyloris
- * trichopol
 - Licviroton
 - oxiferiskorbon
 - atropine
 - pirinzsipin
2199. What from the transferred operations does not belong to organ protective
- trunk vagotomy
 - * resection by Bilrot II
 - selective vagotomy
 - selective proximal vagotomy
 - the all transferred does not belong
2200. What from the transferred operations on the stomach organ protective is
- * selective proximal vagotomy
 - resection by Bilrot I
 - resection by Bilrot II
 - gastrectomy
 - all are transferred
2201. What hormones undertake the protective operating on the mucous membrane of stomach, except for
- * ACTH
 - epidermal factor of growth
 - prostaglandin E
 - estrogens
 - STH
2202. What instrumental examination is performed at jamming of haemorrhoidal nodes
- * examination is not performed
 - rectometer
 - irrigoscopy
 - irrigography
 - colonoscopy
2203. What is from listed has hemostatic effect
- * blood
 - red corpuscles

- C. Haemodesum
 - D. physiologic solution
 - E. glucose
2204. What is indication to surgical treatment of anal fissure
- A. * chronic passing
 - B. acute passing
 - C. perforation
 - D. bleeding
 - E. malignancy
2205. What is location of fistula chanal at intersphincteric paraproctitis?
- A. * Between mucus and sphincter
 - B. Passes through sphincter
 - C. Located after sphincter
 - D. All are true
 - E. All are false
2206. What is location of fistula chanal at the transsphincteric paraproctitis?
- A. Between mucus and sphincter
 - B. * Passes through sphincter
 - C. Located after sphincter
 - D. All is true
 - E. All is false
2207. What is the basic examination of patients with disease of rectosigmoid area?
- A. * Rectoromanoscopy.
 - B. X-Ray.
 - C. Sonography.
 - D. Digital examination of rectum.
 - E. Irrigography.
2208. What is the complication after haemorrhoidectomy
- A. * stricture of anus
 - B. proctosigmoiditis
 - C. cancer of rectum
 - D. intestinal obstruction
 - E. peritonitis
2209. What is the complication of surgical treatment of anal fissures
- A. * insufficiency of anal sphincter
 - B. anterior mucosal prolapse of rectum
 - C. cancer of rectum
 - D. malignancy
 - E. Crohn disease
2210. What is the contra-indication for the colproctectomy at a unspecific ulcerative colitis:
- A. * A perforation of colon bowel
 - B. Acute toxic dilatation
 - C. Bleeding
 - D. Malignizaciya
 - E. Stenosis
2211. What is the operation of choice at a unspecific ulcerative colitis:

- A. Resection of rectum
 - B. * proctocolectomy
 - C. Left-side hemicolectomy
 - D. Right-side hemicolectomy
 - E. Resection of sigmoid bowel
2212. What is the operation of choice at the unspecific ulcerative colitis?
- A. * Proctocolonectomy with ileostomy.
 - B. Bypassed loop anastomosis.
 - C. Subtotal colectomy.
 - D. Resection of colon.
 - E. Application of colostomy.
2213. What is the reason of origin of acute proctitis?
- A. Trauma of rectum
 - B. * Micro-injury of rectum mucus with the damage of crypt
 - C. Proctopolypus
 - D. Anal fissure
 - E. Cancer of rectum
2214. What is the reason of relapse of proctitis?
- A. An operation is done not enough radically
 - B. Infection of wound
 - C. * The internal opening is not removed
 - D. Anaerobic infection
 - E. Wrong conservative treatment
2215. What is the typical localization of anal fissure
- A. * on 6 hr.
 - B. on 12 hr.
 - C. on 3 hr.
 - D. on 9 hr.
 - E. on 2 hr.
2216. What kind of enemas is applied at preparation a patient to the operation?
- A. * Cleaning.
 - B. Siphon.
 - C. Microenema.
 - D. Purgative.
 - E. Does not used.
2217. What layers of the bowel are damaged at Crohn disease
- A. * all of layers
 - B. mucus
 - C. submucous and muscle
 - D. submucous
 - E. muscle
2218. What localization of ulcer is most characteristic for the patients of elderly and senile age
- A. * cardial department of stomach
 - B. overhead third of gullet
 - C. lower third of gullet
 - D. bulb of duodenum
 - E. small curvature

2219. What medicines is used for increasing the frequency of defecation ?
- A. * Prozerin.
 - B. Sulfate of magnesium.
 - C. Immodium.
 - D. Karbolen.
 - E. Digestal.
2220. What medicines is used for treatment of unspecific ulcerative colitis?
- A. * Sulfasalazinum.
 - B. Ampicillin.
 - C. Nospanum, papaverini.
 - D. Aspirine.
 - E. Furazolidonum.
2221. What method diagnostics hte ulcerous illness most informing
- A. * esophagogastroduodenoscopy
 - B. analysis of excrement on the hidden blood
 - C. X-ray
 - D. global analysis of blood
 - E. research of gastric secretion
2222. What method is it orientation possible to define the volume of hemorrhage on at the acute gastroenteric bleeding?
- A. On maintenance red corpuscles, haemoglobin, Ht, thrombocytes
 - B. On blood volume
 - C. * On an arteriotony, pulse, state of patient
 - D. On a globular volume
 - E. On the level of thrombocytes
2223. What method of examination is used to confirm the diagnosis of Crohn disease?
- A. * A biopsy is with histological examination
 - B. CT
 - C. Sciagraphy
 - D. Sonography
 - E. Rectoscoopy
2224. What method of operative treatment is used at the I - IV stage of complicated extrasphincteric fistula?
- A. * Ligature method.
 - B. Rizhikh-1.
 - C. Rizhikh-2.
 - D. Gabriel.
 - E. Cutting and suturing of fistula.
2225. What operation is performed at a acute shoe-shaped paraproctitis ?
- A. Opening of abscess with suturing
 - B. Cutting of abscess (by Gabriel)
 - C. * Opening of abscess with the ligature conduction
 - D. Cutting of abscess with shifting of mucus to distal part of rectum
 - E. Conservative treatment
2226. What operation is performed at an anal fissure?
- A. * Cutting of fissure with sphincterotomy.

- B. Suturing of fissure.
 - C. Operation of Milligan-Morgan.
 - D. Operation of Gabriel.
 - E. Operation of Nobl.
2227. What operation is performed at haemorrhoids complicated by bleeding
- A. * urgent
 - B. planned
 - C. conservative therapy
 - D. physiotherapeutic procedure
 - E. not performed
2228. What operation is performed at haemorrhoids complicated by trombosis
- A. * urgent
 - B. planned
 - C. conservative therapy
 - D. physiotherapeutic procedure
 - E. not performed
2229. What operation is performed at haemorrhoids?
- A. * Operation of Milligan-Morgan.
 - B. Rizhikh-1.
 - C. Rizhikh-2.
 - D. Operation of Gabriel.
 - E. Operation of Blinnichev.
2230. What operation is performed at patient with fissure and polypus?
- A. * Cutting of fissure with polypectomy.
 - B. Cutting of fissure.
 - C. By Milligan-Morgan.
 - D. By Gabriel.
 - E. Operation of Blinnichev.
2231. What operation is performed at rectocaele?
- A. * by Kumel-Zerenin.
 - B. Kenu-Miles.
 - C. Milligan-Morgan.
 - D. Gabriel.
 - E. Operation of Blinnichev.
2232. What operation is performed at the acute subcutaneous paraproctitis?
- A. Opening of abscess with suturing
 - B. * Cutting of abscess (by Gabriel)
 - C. Opening of abscess with the ligature conduction
 - D. Cutting of abscess with shifting of mucus to distal part of rectum
 - E. Conservative treatment
2233. What operation is performed at the Crohn disease?
- A. * A resection of bowel within the limits of healthy tissues.
 - B. Proctocolonectomy.
 - C. Subtotal colectomy.
 - D. Resection of large and small intestine.
 - E. Application of colostomy.

2234. What operation is performed at the extrasphincteric paraproctitis?
- A. Opening of abscess with suturing
 - B. Cutting of abscess (by Gabriel)
 - C. * Opening of abscess with the ligature conduction
 - D. Cutting of abscess with shifting of mucus to distal part of rectum
 - E. Conservative treatment
2235. What operation is performed at the ischiorectal paraproctitis?
- A. Opening of abscess with suturing
 - B. Cutting of abscess (by Gabriel)
 - C. * Opening of abscess with the ligature conduction
 - D. Cutting of abscess with shifting of mucus to distal part of rectum
 - E. Conservative treatment
2236. What operation is performed at the retrorectal paraproctitis?
- A. Opening of abscess with suturing
 - B. Cutting of abscess (by Gabriel)
 - C. * Opening of abscess with the ligature conduction
 - D. Cutting of abscess with shifting of mucus to distal part of rectum
 - E. Conservative treatment
2237. What operation is performed at the transsphincteric paraproctitis?
- A. Cutting of fistula chanal (by Gabriel)
 - B. * Cutting of fistula chanal with the partial suturing of bottom of wound
 - C. Cutting of fistula chanal with the ligature conduction
 - D. Cutting of fistula with shifting of mucus to distal part of rectum
 - E. Conservative treatment
2238. What operation is radical at haemorrhoids?
- A. Suturing of haemorrhoidal nodes
 - B. Operation by Gabriel
 - C. * Operation by Milligan-Morgan
 - D. Sclerotherapy
 - E. Conservative treatment
2239. What operation is used for pararectal fistula?
- A. * Operation of Gabriel.
 - B. Operation of Milligan-Morgan.
 - C. Operation of Gagen-Torn.
 - D. Operation of Nobl.
 - E. A sphincterectomy.
2240. What part of colon is damaged by cancer most often:
- A. * Sigmoid colon
 - B. Caecum
 - C. Ascending part
 - D. Descending part
 - E. Rectum
2241. What part of intestine of most often is a pathological process localized in at Crohn disease?
- A. * Terminal part of small intestine.
 - B. Rectum.
 - C. Ascending part of colon bowel.
 - D. Lumbar part of colon bowel.

- E. Sigmoid bowel.
2242. What patients with poliposis of colon could has in stool:
- A. Nothing
 - B. * Small amount of blood
 - C. Undigested meal
 - D. Presence of part of polypuses
 - E. Melena
2243. What preparation does behave to blocker H2-retseptors?
- A. * tavegil
 - B. obzidan
 - C. hystdol
 - D. cerucal
 - E. oraza
2244. What preparation does behave to blocker of muscarine receptors of coating cages?
- A. cymetidin
 - B. eglonin
 - C. * gastocepini
 - D. etimsiloli
 - E. vinylin
2245. What preparations, except for other properties, own yet and a bacteriostatic effect on Helicobacter pyloris
- A. * all are transferred preparations
 - B. Almagel
 - C. Vinylin
 - D. De-nol
 - E. Claritromycin
2246. What products are recommended in the diet of № 1?
- A. * hen in a steam kind
 - B. pancakes
 - C. raw egg-white
 - D. bread rye fresh
 - E. acute cheeses
2247. What stool has patients with poliposis of colon:
- A. Not changed
 - B. Constipations
 - C. * Diarrhea
 - D. White
 - E. Melena
2248. What syndrome is characteristic for hemorrhagic erosive gastritis?
- A. * ulcerous
 - B. hemorrhagic;
 - C. pain;
 - D. all answers are correct;
 - E. all answers are not correct.
2249. What time urgent operations are executed at acute bleeding
- A. * 6 – 12 hours;

- B. 6 – 10 hours;
 - C. 6 – 8 hours
 - D. 6 – 14 hours;
 - E. 6 – 20 hours
2250. What triad of symptoms is characteristic for an anal fissure
- A. * pain during defecation, spasm of sphincter, bleeding
 - B. pain before defecation, constipations, bleeding
 - C. diarrhea, bleeding, weight loss
 - D. anaemia, diarrhea, pain
 - E. bleeding, anaemia, diarrhea
2251. What violation of mineral exchange is characteristic for patients with ulcerous illness of stomach and intestine
- A. hypocalcemia
 - B. * hypokaliemia
 - C. Hyponatremia
 - D. Hypercalcinemia
 - E. hyperkaliemia
2252. What volume of blood lost at a unspecific ulcerative colitis does consider complications?
- A. To 50 ml
 - B. 50-100 ml
 - C. 150-200 ml
 - D. 200-300 ml
 - E. * 300 ml and more
2253. When apply Teylor's method at ulcerous illness
- A. * at conservative treatment perforated ulcers
 - B. at conservative treatment sanguifluous ulcers
 - C. at conservative treatment penetration ulcers
 - D. at conservative treatment malignization ulcers
 - E. at conservative treatment of cicatrical pyloristensis
2254. Where are anal papilla usually located?
- A. In any area of anal channel
 - B. * Only above and lower from dentata line
 - C. In sygmoid colon
 - D. In any area of rectum
 - E. In perianal region
2255. Which preparation is used for treatment of unspecific ulcerative colitis
- A. * sulfasalasine
 - B. fenolftaleine
 - C. cerucal
 - D. analgin
 - E. ketanov
2256. With the purpose of preventing of anaerobic infection at surgical treatment of paraproctitis is used
- A. * hydrogen peroxide
 - B. furacilini
 - C. iodine solution
 - D. rivanol

- E. alcohol
2257. A frequent liquid stool is the first sign of:
- A. haemorrhoids
 - B. Fissures of anus
 - C. Proctosigmoiditis
 - D. * UUC
 - E. All of answers are correct
2258. A ligature method is used at treatment of paraproctitis
- A. * extrasphincteric fistula
 - B. acute submucous fistula
 - C. intersphincteric fistula
 - D. ischiorectal
 - E. retrorectal
2259. A patient 40 years old, suffered ulcerous diseases of stomach. Last 2 days the pain became less intensive, but weakness and dizziness were appeared. Rose from a bed and lost consciousness. Pale. There are insignificant pains in epigastrium. It is
- A. Combination perforation with bleeding
 - B. Perforation
 - C. Malignization of ulcer
 - D. Stenosis of ulcer
 - E. * Gastroenteric bleeding
2260. A patient after the electroscission of polypus of sigmoid bowel has bleeding. What is tactic?
- A. * it is performed hemostatic therapy
 - B. it is performed operative treatment
 - C. conservative treatment
 - D. laparotomy
 - E. laparoscopy
2261. A patient after the electroscission of polypus of sigmoid bowel has stomach-aches. What complication can be?
- A. * perforation
 - B. bleeding
 - C. malignancy
 - D. toxic dilatation
 - E. penetration
2262. A presence of mucus and pus in stool is characteristic for:
- A. Proctosigmoiditis
 - B. Cancer of rectum
 - C. UUC
 - D. All of answers are wrong
 - E. * All of answers are correct
2263. Absolute indication to operative treatment the ulcerous illness is
- A. heavy pain syndrome
 - B. * perforation of ulcer
 - C. relapses more than 2 one time per a year
 - D. ulcerous anamnesis more than 10 years
 - E. giant ulcers

2264. Absolute indication to operative treatment the ulcerous illness is
- * voluminous bleeding
 - callous ulcers
 - relapses more than 2 one time per a year
 - ulcerous anamnesis more than 10 years
 - heavy pain syndrome
2265. Absolute indication to operative treatment the ulcerous illness is
- ulcerous anamnesis more than 10 years
 - * bleeding what do not stopped with conservative
 - perforation ulcer in anamnesis
 - heavy pain syndrome
 - relapses more than 3 times per a year
2266. Absolute indication to operative treatment the ulcerous illness is
- relapses more than 2 one time per a year
 - ulcerous anamnesis more than 10 years
 - relapse ulcer after the resection of stomach
 - relapses more than 3 times per a year
 - * cicatricial-ulcerous stenosis of pylorus
2267. Absolute indication to operative treatment the ulcerous illness is
- relapses more than 2 one time per a year
 - * malignization ulcers
 - ulcerous anamnesis more than 10 years
 - heavy pain syndrome, proof heartburn
 - relapse ulcer after vagotomy
2268. Absolute sign of unstable hemostasis
- * profluvium blood from a vessel;
 - absence blood in a stomach and bulb of duodenum;
 - presence light blood and faltungs of blood in a stomach;
 - all answers are correct;
 - all answers are not correct
2269. After what operation at ulcerous illness the natural arcade of meal is saved on a digestive tract
- Valter-Braun's gastroenterostomy
 - not saved after any operation
 - resection by Bilrot II
 - * resection by Bil'rot I
 - saved after all transferred operations
2270. After what operation innervation of pyloric department of stomach is saved
- * selective vagotomy
 - barrel vagotomy
 - selective proximal vagotomy
 - at all transferred
 - not saved after all operations
2271. An anal itch is a sign of:
- Insufficiency of sphincter of anus
 - Mycotic lesion of skin of coccyx
 - The hidden diabetes

- D. Intestinal worm invasion
 - E. * All of answers are correct
2272. At a chronic paraproctitis is performed:
- A. * Planned operation.
 - B. Urgent operation.
 - C. Conservative treatment.
 - D. Emergency operation.
 - E. Nothing
2273. At beginning bleeding from an ulcer
- A. * pain diminishes
 - B. pain increases
 - C. there is knife-like pain
 - D. character of pain does not change
 - E. girdle pain
2274. At bleeding emergency operative interferences are executed
- A. * to 3 hours
 - B. to 1,5 hour
 - C. to 6 hours
 - D. to 8 hours
 - E. 6 – 12 hours
2275. At III stage blood loss at the bleeding ulcer the patient loses
- A. over 1000 ml blood
 - B. * over 2000 ml blood
 - C. over 500 ml blood
 - D. over 2500 ml blood
 - E. over 1500 ml blood
2276. At III stage blood loss at the bleeding ulcer the patient loses
- A. more than 25 % blood volume
 - B. * more than 30 % blood volume
 - C. more than 20 % blood volume
 - D. more than 15 % blood volume
 - E. more than 35 % blood volume
2277. At the duodenum ulceroperation of choice is
- A. * resection by Bilrot I
 - B. resection by Bilrot II
 - C. resection of duodenum
 - D. selective proximal vagotomy
 - E. sewing up of ulcer
2278. At the gastroenteric bleeding the middle degree of blood loss is diagnosed at next indexes
- A. Hb below 80 g/l
 - B. * Hb 80-100 g/l
 - C. red corpuscles below $2,5 \cdot 10^{12}/l$
 - D. red corpuscles of $3,5-4,0 \cdot 10^{12}/l$
 - E. Ht below 25%
2279. At the III item of activity hemostasis and III sage blood loss from the I – III sage blood loss indicated

- A. * urgent operations (6 – 12 hours);
 - B. emergency operations (to 3 hours);
 - C. exigent operations (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
2280. At the V item activity of hemostasis and at the recurrent bleeding of the I – III item of blood loss indicated
- A. * emergency operations (to 3 hours);
 - B. urgent operations (6 – 12 hours);
 - C. exigent (12 – 24 hours);
 - D. early deferred (24 – 72 hours);
 - E. planned operations (4 – 10 days)
2281. At ulcerous illness can a bleeding source be
- A. artery;
 - B. veins;
 - C. shallow vessels and ulcers;
 - D. all answers are not correct.
 - E. * all answers are correct
2282. At what disease could be histologically unspecific granuloma
- A. * Crohn disease
 - B. unspecific ulcerative colitis
 - C. cancer of rectum
 - D. poliposis
 - E. diverticulosis
2283. Bergman's sign is characteristic for
- A. * bleeding ulcer
 - B. for cicatricial-ulcerous pylorostenosis
 - C. perforated ulcers
 - D. penetration ulcers
 - E. malignization ulcers
2284. Berhstein's sign characteristic for
- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorostenosis
2285. Bleeding ulcer, complicated blood loss III stage degrees, requires
- A. * blood and its components transfusions
 - B. transfusion of salt solutions
 - C. transfusion of colloid solutions
 - D. transfusion of salt and colloid solutions
 - E. infusion therapy does not need
2286. Blood loss I stage characterized such indexes
- A. Ht 48-44, Hb 120
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 31-23, Hb 80
 - D. * Ht 38-32, Hb 100

- E. Ht 44-40, Hb 110 /?
2287. Blood loos II stage characterized
- A. * Ht 23 and below, Hb 50 and below
 - B. Ht 31-23, Hb 80
 - C. Ht 44-40, Hb 110
 - D. Ht 48-44, Hb 120
 - E. Ht 48-44, Hb 120
2288. Blood loos III stage characterized a degree such indexes
- A. * Ht 31-23, Hb 80
 - B. Ht 23 and below, Hb 50 and below
 - C. Ht 38-32, Hb 100
 - D. Ht 44-40, Hb 110
 - E. Ht 48-44, Hb 120
2289. Classification of haemorrhoids by the clinical passing
- A. * complicated, non-complicated
 - B. I, II, III stage
 - C. external, internal
 - D. I, II stage
 - E. all are false
2290. Classification of haemorrhoids by the degrees
- A. * I, II, III of the stage
 - B. external, internal
 - C. complicated, non-complicated
 - D. I, II stage
 - E. all are false
2291. Classification of haemorrhoids by the localizations
- A. * external, internal
 - B. I, II, III of the stage
 - C. complicated, non-complicated
 - D. I, II stage
 - E. all are false
2292. Classification of paraproctitis depending on activity of inflammatory process
- A. * acute, chronic
 - B. banal, specific, posttraumatic
 - C. perianal, submucous, ischiorectal, pelviorectal, retrorectal
 - D. front, lateral, back
 - E. Intersphincteric, transsphincteric, extrasphincteric
2293. Classification of paraproctitis depending on etiologic sign
- A. * banal, specific, posttraumatic
 - B. acute, chronic
 - C. perianal, submucos, ischiorectal, pelviorectal, retrorectal
 - D. front, lateral, back
 - E. Intersphincteric, transsphincteric, extrasphincteric
2294. Classification of paraproctitis depending on fistula localisation
- A. * Intersphincteric, transsphincteric, extrasphincteric
 - B. banal, specific, posttraumatic

- C. acute, chronic
 - D. front, lateral, back
 - E. perianal, submucous, Ischiorectal, pelvirectal, retrorectal
2295. Classification of paraproctitis depending on localizations
- A. * perianal, submucos, Ischiorectal, pelvirectal, retrorectal
 - B. banal, specific, posttraumatic
 - C. acute, chronic
 - D. front, lateral, back
 - E. Intersphincteric, transsphincteric, extrasphincteric
2296. Clinical manifestation of acute paraproctitis
- A. * pain, high temperature
 - B. enterorrhagia
 - C. diarrhea
 - D. constipations
 - E. vomiting
2297. Complication of haemorrhoids
- A. * thromboses, bleeding, paraproctitis
 - B. Crohn disease
 - C. portal hypertension
 - D. perforation
 - E. malignancy
2298. Complication of surgical treatment of anal fissures
- A. * insufficiency of anal sphincter
 - B. perforation
 - C. cancer of rectum
 - D. malignancy
 - E. Crohn disease
2299. Contr-indication to the operation of haemorrhoidectomy is
- A. * portal hypertension
 - B. bleeding
 - C. repeated thrombosis
 - D. pain
 - E. itch
2300. De-Cerven's sign is characteristic for
- A. bleeding ulcer
 - B. * perforated ulcers
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorostenosis
2301. Diet at bleeding gastric and duodenum ulcers
- A. * Meulengracht's
 - B. 1 by Pevznerom
 - C. 5 by Pevznerom
 - D. 15 by Pevznerom
 - E. 7 by Pevznerom
2302. Disappearance or diminishing the pain with beginning of bleeding from an ulcer is

- A. * Bergman's sign
 - B. Spazarskiy's sign
 - C. Mendel's sign
 - D. De Keven's sign
 - E. Eleker's sign
2303. Duration the period of primary shock at a perforated ulcer
- A. * 3-6 hours
 - B. 6-12 hours
 - C. 1-3 hours
 - D. 12-24 hours
 - E. 24-36 hours
2304. During rectoscopy is found the endoscopic symptom of "roadway". What disease?
- A. Unspecific ulcerative colitis
 - B. * Crohn disease of rectum
 - C. Dysentery
 - D. Salmonellosis
 - E. Syndrome of irritation of colon
2305. Eleker's sign is characteristic for
- A. * perforated ulcers
 - B. bleeding ulcer
 - C. penetrated ulcers
 - D. malignized ulcers
 - E. for cicatricial-ulcerous pylorostenosis
2306. Esophagogastroduodenoscopy can find out next changes in a stomach, except for
- A. tumours
 - B. ulcers
 - C. bleeding polypuses
 - D. erosions
 - E. * changes of evacuation function
2307. Features of surgical treatment of anaerobic paraproctitis
- A. * opening by wide cuts
 - B. ligature method
 - C. operation of Gabriel
 - D. an operation by Rizhik-Bobroviy
 - E. by Milligan-Morgan and Gabriel.
2308. For bleeding ulcer characteristic sign is
- A. * pain in an epigastrium;
 - B. knife-like pain;
 - C. signs irritation of peritoneum;
 - D. presence fresh blood in incandescence
 - E. melena;
2309. For bleeding ulcer characteristically
- A. * melena
 - B. tension the muscles of front abdominal wall
 - C. Spazarskiy's sign
 - D. sickliness the back vault of vagina
 - E. irradiation pain in a shoulder or shoulder-blade

2310. For motion of disease ulcerous illness of middle weight characteristically
- A. development of complications
 - B. * relapses 1-2 times per a year
 - C. 4 and anymore relapses on a year
 - D. 5 and more relapses are on a year
 - E. 3 and anymore relapses on a year
2311. For perforated ulcer characteristically
- A. * tension the muscles of front abdominal wall
 - B. melena
 - C. vomiting by coffee-grounds
 - D. high intestinal impassability
 - E. vomiting stagnant gastric maintenance
2312. For pneumoperitoneum is characteristic symptom
- A. * Zhober's;
 - B. Khelatid's;
 - C. Podlag's;
 - D. Vigats's;
 - E. Udin's.
2313. For the heavy flow of ulcerous illness characteristically
- A. 2 and anymore relapses on a year
 - B. * 3 and anymore relapses on a year
 - C. 4 and anymore relapses on a year
 - D. 5 and more relapses are on a year
 - E. 6 and more relapses are on a year
2314. For the heavy flow of ulcerous illness characteristically
- A. * development of complications
 - B. seasonal exacerbation more not frequent 1-2 times per a year
 - C. 1-2 relapse on a year
 - D. liquid, but protracted exacerbation
 - E. exacerbation duration more than 10 days
2315. For what disease characteristic symptom of "water-pipe"?
- A. * Unspecific ulcerative colitis.
 - B. Crohn disease.
 - C. Pseudopoliposis.
 - D. Diverticulosis.
 - E. Spastic colitis.
2316. For what disease is characteristic symptom of "roadway"?
- A. * Crohn disease.
 - B. Amebioz.
 - C. Spastic colitis.
 - D. Cancer of large intestine.
 - E. Unspecific ulcerative colitis.
2317. For which diseases of large intestine characteristic symptom of the "shot target"?
- A. * unspecific ulcerative colitis
 - B. diverticulosis
 - C. poliposis

- D. cancer
 - E. Crohn disease
2318. From what department degestive tract developmentp more frequent than all the bleeding at the Mallory-Weiss syndrome
- A. gastric fundus
 - B. * cardial pert;
 - C. pyloric department;
 - D. from duodenal;
 - E. from a thick intestine
2319. From what part of gastrointestinal tract is bleeding when presence of cherry-colour blood in the stool
- A. * colon
 - B. stomach and duodenum
 - C. rectum
 - D. duodenum
 - E. small intestine
2320. From what part of intestine is most often begins unspecific ulcerative colitis?
- A. * From the rectum.
 - B. From the ascending part of colon.
 - C. From the transverse part of colon.
 - D. From the descent part of colon.
 - E. From the terminal part of small intestine.
2321. From what tissue anal papilla are formed from?
- A. From epithelial tissue
 - B. * From connective tissue
 - C. From limphoid tissue
 - D. From muscular tissue
 - E. From mucus
2322. Giant ulcer is an ulcer measuring
- A. over 4,5 cm
 - B. * over 3 cm
 - C. over 4 cm
 - D. over 5 cm
 - E. over 3,5 cm
2323. Haemorrhoid's nodes do not fall out at
- A. * I stage
 - B. II stage
 - C. III stage
 - D. External nodes
 - E. Internal nodes
2324. Haemorrhoid's nodes fall out and not replaced
- A. * III stage
 - B. I stage
 - C. II stage
 - D. External nodes
 - E. Internal nodes

2325. Haemorrhoid's nodes fall out during defecation and replaced
- A. * II stage
 - B. I stage
 - C. III stage
 - D. External nodes
 - E. Internal nodes
2326. Haemorrhoidectomy is complicated by cicatricial stricture of rectum. What next operation is indicated?
- A. * dosed sphincterotomy with sewing mucus of rectum to the perianal skin
 - B. anal bougienage
 - C. dosed sphincterotomy
 - D. hemorrhoidectomy
 - E. colostomy
2327. Haemorrhoids complicated by bleeding is indication for
- A. * urgent operation
 - B. planned operation
 - C. conservative therapy
 - D. physiotherapeutic procedure
 - E. therapy not performed
2328. Haemorrhoids complicated by trombosis is indication for
- A. * urgent operation
 - B. planned operation
 - C. conservative therapy
 - D. physiotherapeutic procedure
 - E. therapy not performed
2329. Hemobilia is
- A. * all answers are correct;
 - B. bleeding the bilious ways and liver;
 - C. bleeding the general bilious channel;
 - D. bloody clot in the big duodenal papilla;
 - E. all answers are not correct.
2330. How many physiology flexures has rectum?
- A. 1
 - B. * 2
 - C. 3
 - D. 4
 - E. 5
2331. Hyperbaric oxygenation in a postoperative period is used at:
- A. * Anaerobic paraproctitis
 - B. To the anal fissure
 - C. Epithelial coccygeal
 - D. Haemorrhoids
 - E. Cancer of rectum
2332. In the perianal area patient has the slight swelling, red skins, soft infiltrate. What is the diagnosis?
- A. * Acute paraproctitis
 - B. Anal fissure

- C. Haemorrhoids
- D. Cancer of rectum
- E. Proctopolypus

2333. In what amount of physiologic solution does dissolve medicines for medical micro-enemas?

- A. * 80 ml.
- B. 200 ml.
- C. 250 ml.
- D. 300 ml
- E. 400 ml

2334. In what area of stomach practically never is not origin of ulcers, or it is extraordinarily rarely?

- A. small curvature of stomach;
- B. back wall of stomach, nearer to small curvature;
- C. large curvature of stomach
- D. * cardiac part of stomach;
- E. pylorus.

2335. In what vein is a venous outflow carried out in from a stomach?

- A. * V. Portae;
- B. V. odd;
- C. V. pair;
- D. V. overhead hollow;
- E. V. lower hollow;

2336. Indication to the operation of haemorrhoidectomy is

- A. * thrombosis of haemorrhoids nodes
- B. portal hypertension
- C. pain
- D. itch
- E. discomfort

2337. Indication to the operation of haemorrhoidectomy is

- A. * repeated thrombosis of haemorrhoids nodes
- B. portal hypertension
- C. second stage of non-complicated haemorrhoids
- D. first stage of non-complicated haemorrhoids
- E. itch

2338. Large ulcer is an ulcer measuring

- A. 1-4 cm
- B. 1-3 cm
- C. 3-5 cm
- D. 2- 6 cm
- E. * 2-3 cm

2339. Little ulcer it is an ulcer measuring

- A. * to 0,5 cm
- B. 0,5-1 cm
- C. to 1,0 cm
- D. 3 to 1,5 cm
- E. 0,5-1,5 cm

2340. Mark the disease of colon, which characterised by such complications as bleeding, formation of stricture, perforation, toxic dilatation, malignancy:
- A. Haemorrhoids
 - B. Fissure
 - C. Polipus
 - D. * Unspecific ulcerative colitis
 - E. Paraproctitis
2341. Meets the most frequent localization bleeding the digestive tract is
- A. gullet;
 - B. stomach;
 - C. rectum;
 - D. * duodenum;
 - E. colon
2342. Melena is
- A. black designed chair
 - B. * black liquid tarry chair
 - C. a discoloured liquid excrement
 - D. foamy stinking emptying of black
 - E. an excrement designed veined blood
2343. Melena is a characteristic sign
- A. * bleeding ulcer
 - B. for cicatrical-ulcerous pylorus stenosis
 - C. perforated ulcers
 - D. penetration ulcers
 - E. malignization ulcers
2344. Method of surgical treatment of acute submucous paraproctitis
- A. * by Rizhik-Bobroviy
 - B. opening of abscess by a radial cut
 - C. ligature method
 - D. Operation of Rizhikh-1.
 - E. by Milligan-Morgan.
2345. Method of surgical treatment of anal fissure
- A. * cutting of fissure
 - B. by Milligan-Morgan.
 - C. suturing of fissure
 - D. by Kyumel-Zerenin.
 - E. by Kenyu-Milse.
2346. Method of surgical treatment of haemorrhoids
- A. * by Milligan-Morgan.
 - B. by Bebkok
 - C. by Narat
 - D. by Gabriel.
 - E. Operation of Blinnichev.
2347. Most informing method at a bleeding ulcer
- A. survey sciagraphy the organs of abdominal region
 - B. * EFGDS
 - C. sciagraphy the stomach with contrasting

- D. Sonography
 - E. Laparoscopy
2348. Name classic complications of ulcerous illness
- A. bleeding, pylorostenosis, second pancreatitis, malignization, perforation
 - B. * perforation, penetration, bleeding, pylorostenosis, malignization
 - C. malignization, pylorostenosis, penetration, anaemia, perforation
 - D. bleeding, perforation, second pancreatitis, anaemia, malignization
 - E. perforation, peritonitis, pancreatitis, bleeding, penetration
2349. On irrigography is found the symptoms of «water-pipe», «shot through target». What is diagnosis?
- A. * Unspecific ulcerative colitis
 - B. Crohn disease
 - C. Dysentery
 - D. Salmonellosis
 - E. Food toxicoinfection
2350. Operating access at operations on a stomach
- A. * Upper-middle laparotomy
 - B. Lower-middle laparotomy
 - C. Pararectum access
 - D. Volokovich-Dyakonov's access
 - E. Pfanenhtil's access
2351. Operation which performed after the cutting of fissure of rectum
- A. * by Gabriel
 - B. by Milligan-Morgan.
 - C. sphincterotomy
 - D. by Kyumel-Zerenin.
 - E. by Kenyu-Miles.
2352. Patient which the gastroenteric bleeding in house is necessary
- A. * To send a patient in surgical permanent establishment
 - B. To appoint rest, enter Cacl, vicasol
 - C. To wash a stomach, appoint a cold, rest of supervision
 - D. To send a patient in a therapeutic gastroenterology separation
 - E. A right answer absents
2353. Patient 27 years old has stomach-ache, liquid stool up to 10 times per days with mucus and blood, weakness, weight lost. On the irrigography is narrowing of transvers colon. What diagnosis?
- A. Dysentery.
 - B. Polypus of small intestine.
 - C. * Cancer of transvers colon.
 - D. Spastic colitis.
 - E. Unspecific ulcerative colitis
2354. Patient 50 years old has permanent pain in the anus, frequent defecation with blood, lost of appetite, weight lost, weakness. What examination is prescribed?
- A. * A biopsy with histological examination
 - B. Radio-active scan
 - C. Selective angiography
 - D. Doplerography

E. Sonography

2355. Patient 59 years old has suspicion of the tumour of ascending part of colon. What method of examination is the best?
- A. * A colonoscopy with a biopsy
 - B. Irrigography
 - C. Survey sciagraphy
 - D. Sonography
 - E. Endoscopy
2356. Patient 72 years old has acute pain in the left half of abdomen, nausea, delay of stool and gases. He is ill 6 hours. No mucus and blood in stool, not weight lost. Pulse 84 per 1 min. Peristaltic noises are increased periodically. On the X-Ray of organs of abdominal region is present the Kloyber's cup in the left half of abdomen. What diagnosis?
- A. * Invagination of sigmoid bowel
 - B. Crohn disease
 - C. Poliposis
 - D. Unspecific ulcerative colitis
 - E. Diverticulosis
2357. Patient during the act of defecation has pain in anal channel, red blood in the stool. What disease?
- A. * Anal fissure
 - B. Haemorrhoids
 - C. Acute paraproctitis
 - D. Cancer of rectum
 - E. Proctopolypus
2358. Patient has poliposis of right half of colon. What is treatment?
- A. * right hemicolectomy
 - B. conservative treatment
 - C. stoma
 - D. by Milligan-Morgan.
 - E. by Gabriel.
2359. Patient has a blood in the first portions of stool. What disease is possible?
- A. * Cancer of rectum.
 - B. Haemorrhoids.
 - C. Fissure.
 - D. Paraproctitis.
 - E. Fistula.
2360. Patient has a general weakness, presence of dark blood in the stool. At a rectoscopy on 11 cm from anus is found the circular narrowing of rectum. What diagnosis?
- A. * Cancer of rectum
 - B. Proctopolypus
 - C. Acute paraproctitis
 - D. Chronic paraproctitis
 - E. Acute proctitis
2361. Patient has a red blood at the end of defecation. What disease is possible?
- A. * Haemorrhoids and fissure of mucus of rectum.
 - B. Gastric and duodenal ulcers.
 - C. Cancer of rectum.

- D. Paraproctitis.
 - E. Fistula.
2362. Patient has anal fissure of mucus of rectum with periodic pains. Pregnancy 16 weeks. Tactic of surgeon?
- A. * an operation - cutting of fissure after birth of child
 - B. an operation by Milligan-Morgan
 - C. an operation by Gabriel
 - D. cutting of fissure
 - E. an operation by Kenu-Miles
2363. Patient has anterior mucosal prolapse of rectum of the III stage and complete prolapse of uterus. What operation is indicated?
- A. * By Kumel-Zerenin, amputation of uterus
 - B. by Kenu-Miles
 - C. by Tartu
 - D. by Rizhikh-1
 - E. by Milligan-Morgan
2364. Patient has bleeding from a colon as a result of complication of unspecific ulcerative colitis. What operation is indicated?
- A. * proctocolectomy
 - B. suturing of bleeding area of bowel
 - C. resection of bowel
 - D. colectomy
 - E. colostomy
2365. Patient has cicatricial narrowing of sigmoid bowel with intestinal obstruction as complication of unspecific ulcerative colitis. What operation is indicated?
- A. * proctocolectomy
 - B. resection of the narrowed area of bowel
 - C. colectomy
 - D. colostomy
 - E. Operation by Kenyu-Miles.
2366. Patient has diarrhea up to 25-30 times per days with blood, has weight lost, general weakness, periodic stomach-ache. He is ill during 1,5 month. What diagnosis?
- A. * Unspecific ulcerative colitis
 - B. colitis
 - C. Pseudopoliposis
 - D. Diverticulosis
 - E. Spastic colitis
2367. Patient has intersphincteric fistula and external haemorrhoids. What operation is performed?
- A. * By Milligan-Morgan and Gabriel.
 - B. By Milligan-Morgan.
 - C. By Gabriel.
 - D. Operation of Blinnichev.
 - E. Operation of Rizhikh-1.
2368. Patient has long-term ulcer of rectum. In anamnesis white plague. What is previous diagnosis?
- A. * tuberculosis of rectum
 - B. haemorrhoids

- C. proctitis
 - D. fistula
 - E. fissure of rectum
2369. Patient has melena. What is the source of bleeding?
- A. * Stomach and duodenum.
 - B. Rectum.
 - C. Colon.
 - D. Small intestine.
 - E. Sigmoid bowel.
2370. Patient has proctitis and fistula in perirectal area. Also it is present fruzi of actinomicete. What diagnosis?
- A. * actinomycosis
 - B. haemorrhoids
 - C. proctitis
 - D. fistula
 - E. fissure of rectum
2371. Patient has perforation of colon as complication of unspecific ulcerative colitis. What operation is indicated
- A. * proctocolectomy
 - B. suturing of the perforative hole
 - C. resection of area of bowel
 - D. colectomy
 - E. colostomy
2372. Patient has poliposis of left half of colon. What is treatment?
- A. * left-side hemicolectomy
 - B. conservative treatment
 - C. stoma
 - D. by Milligan-Morgan.
 - E. by Gabriel.
2373. Patient has polypus of sigmoid colon with signs of malignancy. What treatment?
- A. * resection of area of bowel with polypus
 - B. electroscission
 - C. cutting of polypus
 - D. criodestruction
 - E. conservative
2374. Patient has polypus on wide leg on 15 sm from anus. What treatment?
- A. * removal of polypus by laparotomy, rectotomy
 - B. electroscission
 - C. conservative treatment
 - D. ligating
 - E. criodestruction
2375. Patient has proctopolypus on 15 sm from anus with the signs of mamalignancy
- A. * anterior resection of rectum
 - B. electroscission
 - C. cutting of polypus
 - D. criodestruction
 - E. conservative

2376. Patient has small sizes proctopolypus in sygmoid bowel and pregnancy 8 weeks. Tactic of surgeon?
- * it is removing polypus after birth of child
 - an operation by Milligan-Morgan
 - an operation by Gabriel
 - cutting of polypus during pregnancy
 - an operation by By Kenu-Miles
2377. Patient has swelling from an anal channel during the act of defecation, without paine, with fresh blood after defecation. Previous diagnosis?
- Anal fissure
 - * Haemorrhoids
 - Acute paraproctitis
 - Cancer of rectum
 - Proctopolypus
2378. Patient has the combined haemorrhoids and pregnancy 8 weeks. Tactic of surgeons?
- * it is performed operative treatment after birth of child
 - an operation by Gabriel
 - an operation by Milligan-Morgan
 - by Rizhikh-1
 - by Kenu-Miles
2379. Patient has the combined haemorrhoids with bleeding and pregnancy 9 weeks. Tactic of surgeon?
- * an operation by Milligan-Morgan
 - an operation by Gabriel
 - it is performed operative treatment after birth of child
 - by Rizhikh-1
 - by Kenu-Miles
2380. Patient has the III stage anterior mucosal prolapse of rectum. What operation is indicated?
- * by Kyumel-Zerenin
 - by Kenyu-Miles
 - by Milligan-Morgan
 - by Gabriel
 - by Rizhikh-1
2381. Patient has toxic dilatation as complication of unspecific ulcerative colitis. What operation is indicated?
- * proctocolectomy
 - resection of dilatated area of colon
 - colectomy
 - colostomy
 - an operation by Kenu-Miles
2382. Patient has ulcer of rectum by duration near two months. The reaction of Wassermann is positive. Previous diagnosis
- * venereal lymphogranuloma
 - haemorrhoids
 - paraproctitis
 - fistula
 - fissure of rectum

2383. Patients with haemorrhoids has blood in the stool
- A. * during defecation
 - B. before defecation
 - C. after defecation
 - D. constantly
 - E. never
2384. Presence of blood in the stool is characteristically for:
- A. haemorrhoids
 - B. UUC
 - C. Cancer of colon
 - D. Fissures of anus
 - E. * All of answers are correct
2385. Radical operation at a bleeding gastric ulcer and duodenum consists in
- A. sewing vessels on a draught;
 - B. * vagotomy or resection the stomach;
 - C. sewing vessels in an ulcer;
 - D. gastroenteroanastomosis;
 - E. all answers are faithful
2386. Reasons of origin of fissures of rectum
- A. * constipations, diarrhoea
 - B. cancer of rectum
 - C. portal hypertension
 - D. ulcerous disease
 - E. varicose disease
2387. Relative absolute indication to operative treatment ulcerous illness is
- A. * penetration of ulcer
 - B. ulcerous anamnesis more than 15 years
 - C. malignization ulcers
 - D. perforation of ulcer
 - E. relapses more than 3 times per a year
2388. Resection of stomach by Bilrot II belongs to
- A. * radical operation
 - B. palliative operation
 - C. draining operations
 - D. organ protect operation
 - E. does not belong to any group
2389. Roentgenological signs of unspecific ulcerative colitis
- A. * symptom of "water-pipe"
 - B. symptom of "niche"
 - C. defect of filling
 - D. symptom of «roadway»
 - E. bowls of Kloyber
2390. Selective proximal vagotomy belongs to
- A. palliative
 - B. draining
 - C. * organ protect operation

- D. resection
 - E. does not belong to any group
2391. Signs of stable hemostasis
- A. * absence blood in a stomach and duodenum bulb;
 - B. presence the light blood and faltungs of blood in a stomach;
 - C. profluvium blood from a vessel;
 - D. all answers correct;
 - E. all answers are not correct
2392. Signs of unstable hemostasis
- A. * the pulsation of vessel is determined;
 - B. the bottom ulcer is covered a fibrin;
 - C. profluvium blood from a vessel;
 - D. all answers are correct;
 - E. all answers are not correct.
2393. Small amount of blood in stool could has patients with:
- A. * Poliposis
 - B. Colitis
 - C. Pancreatitis
 - D. Peptic ulcer disease
 - E. Appendicitis
2394. Solution of atropine sulfate is used, before operation with a purpose
- A. * of block of peripheral M-cholinoreceptors
 - B. providing of the adequate anaesthetizing
 - C. increase of vagus activity
 - D. increasing of frequency of pulse
 - E. decreasing of frequency of pulse
2395. Surgical treatment by the method of cutting of fistula of rectum with cutting of skin and subcutaneous tissue in the type of triangle
- A. * for Gabriel
 - B. for Rizhik-Bobroviy
 - C. ligature method
 - D. by Milligan-Morgan.
 - E. Operation of Rizhikh-1.
2396. Surgical treatment of paraproctitis by the method of desection of fistula of rectum with cutting of skin and mucus in the type of triangle
- A. * by Rizhik-Bobrov
 - B. by Gabriel
 - C. ligature method
 - D. by Milligan-Morgan.
 - E. Operation of Rizhikh-1.
2397. The medicinal “constipation” is used at operations
- A. * on a rectum
 - B. on a small intestine
 - C. on a liver
 - D. on a stomach
 - E. on a duodenum

2398. The nosotropic mechanisms bleedingness at ulcerous illness is
- * all answers are correct.
 - permanent hyperemia all system of stomach
 - different degree dystrophy of superficial layers the mucus shell
 - accumulation the central mucopolysaccharides
 - hypoplastic, dystrophic processes
2399. The secretory function stomach is carried out the next membrane of stomach
- * mucous membrane
 - internal muscular layer
 - serosal
 - mucous submembrane
 - external layer
2400. To absolute indication to operative interference at ulcerous illness does not belong
- * scarry-ulcerous stenosis
 - perforation of ulcer
 - profuse bleeding
 - diameter ulcer a more than 3 cm
 - bleeding what does not stopped with conservative
2401. To the gastric – intestinal bleeding of un ulcerous etiology belong
- * Mallory-Weiss syndrome;
 - hemorrhagic erosive gastritis;
 - diseases by Randyu – Oslera – Vebera;
 - Menetrie's sing;
 - all answers are correct.
2402. Udin's sing at a perforated ulcer is
- * feeling at palpation shove the gases which penetrate through the perforated opening
 - dulling perforated sound in the lateral departments of stomach
 - disappearance of hepatic dullness
 - irradiation pain in a shoulder or shoulder-blade
 - sickliness the back vault of vagina
2403. Vomiting coffee-grounds is a characteristic sign
- * bleeding ulcer
 - penetrative ulcers
 - perforated ulcers
 - malignized ulcers
 - for cicatrical-ulcerous pylorus stenosis
2404. Vomiting what arose up in 4-6 hours after eating characteristic for
- chronic alcoholic gastritis
 - cancer and ulcers of cardia
 - * pylorus ulcers
 - achalasia of gullet
 - ulcer and cancer the body of stomach
2405. What colouring of chair is most characteristic for bleeding from the ulcer of stomach and duodwnum?
- * Tarry excrement
 - Presence on the formed excrement of strokes of red blood
 - Littlechanged blood in an excrement

- D. Excrement of the raspberry colouring with the admixtures of mucus
 - E. Acholic excrement
2406. What complication of unspecific ulcerative colitis is indication to urgent surgery?
- A. Malignizaciya
 - B. Bleeding
 - C. Acute toxic dilatation
 - D. * Perforation
 - E. Diarrhea
2407. What complication the ulcerous illness of stomach is most characteristically for the patients of elderly and senile age
- A. perforation
 - B. perforation + bleeding
 - C. pylorus stenosis
 - D. malignization + penetration
 - E. * bleeding
2408. What disease is damage the superficial layer of wall of bowel
- A. * unspecific ulcerative colitis
 - B. Crohn disease
 - C. diverticulosis
 - D. poliposis
 - E. haemorrhoids
2409. What does mean a term "haemorrhoids"?
- A. Varicose enlargement of haemorrhoidal veins
 - B. Spasm of anal sphincter
 - C. * Bleeding
 - D. Inflammation of paraperctal tissue
 - E. Inflammation of anal channel
2410. What does subserve to development of haemorrhoidal thrombosis?
- A. Constipation
 - B. Diarrhea
 - C. * Spasm of sphincter
 - D. Criptitis
 - E. Papillitis
2411. What drug has purgative action?
- A. * Fenolftalein.
 - B. Aspirine.
 - C. Ftalasol.
 - D. Proserin.
 - E. Biphicol.
2412. What drug is decreased frequency of defecation?
- A. * Immodium.
 - B. Kofeol.
 - C. Karbolen.
 - D. Sulfate of magnesium.
 - E. Prozerin.
2413. What drug is used for fistulography?

- A. * Iodlipol.
 - B. Bilignost.
 - C. Verografin.
 - D. Sulfate of barium.
 - E. Methylene bluing.
2414. What drug is used for irrihography?
- A. * Sulfate of barium.
 - B. Cardiotrast.
 - C. Bilignost.
 - D. Iodlipol.
 - E. Methylene.
2415. What drugs is used to decrease meteorism?
- A. * Espumisan.
 - B. Norsulfazolum.
 - C. Vaseline oil.
 - D. Sulfate of magnesium.
 - E. Prozerin.
2416. What enema is used at intestinal obstruction?
- A. * Siphon enema.
 - B. Cleansing.
 - C. Microenema.
 - D. Purgative.
 - E. Does not used.
2417. What external signs are characteristic for the profuse bleeding from a gastric ulcer?
- A. Vomiting by the littlechanged blood, excrement of the raspberry colouring
 - B. * Vomiting by the littlechanged blood, tarry darkly-cherry chair
 - C. Vomiting by a complete mouth by dark blood with clots, black formed excrement
 - D. Vomiting on the type of "coffee-grounds", presence on the formed incandescence of strokes of red blood
 - E. Tarry darkly-cherry chair
2418. What form of unspecific ulcerative colitis is most dangerous?
- A. * Fulminating.
 - B. Acute.
 - C. Chronic recurrent.
 - D. Chronic continuous.
 - E. Recurrent.
2419. What from preparations has the expressed bacteriostatic action on Helicobacter pyloris
- A. * trichopol
 - B. Liciviroton
 - C. oxiferiskorbon
 - D. atropine
 - E. pirinzsipin
2420. What from the transferred operations does not belong to organ protective
- A. trunk vagotomy
 - B. * resection by Bilrot II
 - C. selective vagotomy
 - D. selective proximal vagotomy

- E. the all transferred does not belong
2421. What from the transferred operations on the stomach organ protective is
- A. * selective proximal vagotomy
 - B. resection by Bilrot I
 - C. resection by Bilrot II
 - D. gastrectomy
 - E. all are transferred
2422. What hormones undertake the protective operating on the mucous membrane of stomach, except for
- A. * ACTH
 - B. epidermal factor of growth
 - C. prostaglandin E
 - D. estrogens
 - E. STH
2423. What instrumental examination is performed at jamming of haemorrhoidal nodes
- A. * examination is not performed
 - B. rectometer
 - C. irrigoscopy
 - D. irrigography
 - E. colonoscopy
2424. What is from listed has hemostatic effect
- A. * blood
 - B. red corpuscles
 - C. Haemodesum
 - D. physiologic solution
 - E. glucose
2425. What is indication to surgical treatment of anal fissure
- A. * chronic passing
 - B. acute passing
 - C. perforation
 - D. bleeding
 - E. malignancy
2426. What is location of fistula chanal at intersphincteric paraproctitis?
- A. * Between mucus and sphincter
 - B. Passes through sphincter
 - C. Located after sphincter
 - D. All are true
 - E. All are false
2427. What is location of fistula chanal at the transsphincteric paraproctitis?
- A. Between mucus and sphincter
 - B. * Passes through sphincter
 - C. Located after sphincter
 - D. All is true
 - E. All is false
2428. What is the basic examination of patients with disease of rectosigmoid area?
- A. * Rectoromanoscopy.

- B. X-Ray.
 - C. Sonography.
 - D. Digital examination of rectum.
 - E. Irrigography.
2429. What is the complication after haemorrhoidectomy
- A. * stricture of anus
 - B. proctosygmoiditis
 - C. cancer of rectum
 - D. intestinal obstruction
 - E. peritonitis
2430. What is the complication of surgical treatment of anal fissures
- A. * insufficiency of anal sphincter
 - B. anterior mucosal prolapse of rectum
 - C. cancer of rectum
 - D. malignancy
 - E. Crohn disease
2431. What is the contra-indication for the colproctectomy at a unspecific ulcerative colitis:
- A. * A perforation of colon bowel
 - B. Acute toxic dilatation
 - C. Bleeding
 - D. Malignizaciya
 - E. Stenosis
2432. What is the operation of choice at a unspecific ulcerative colitis:
- A. Resection of rectum
 - B. * proctocolectomy
 - C. Left-side hemicolectomy
 - D. Right-side hemicolectomy
 - E. Resection of sygmoid bowel
2433. What is the operation of choice at the unspecific ulcerative colitis?
- A. * Proctocolonectomy with Ileostomy.
 - B. Bypassed loop anastomosis.
 - C. Subtotal colectomy.
 - D. Resection of colon.
 - E. Application of colostomy.
2434. What is the reason of origin of acute paraproctitis?
- A. Trauma of rectum
 - B. * Micro-injury of rectum mucus with the damage of crypt
 - C. Proctopolypus
 - D. Anal fissure
 - E. Cancer of rectum
2435. What is the reason of relapse of paraproctitis?
- A. An operation is done not enough radically
 - B. Infection of wound
 - C. * The internal opening is not removed
 - D. Anaerobic infection
 - E. Wrong conservative treatment

2436. What is the typical localization of anal fissure
- * on 6 hr.
 - on 12 hr.
 - on 3 hr.
 - on 9 hr.
 - on 2 hr.
2437. What kind of enemas is applied at preparation a patient to the operation?
- * Cleaning.
 - Siphon.
 - Microenema.
 - Purgative.
 - Does not used.
2438. What layers of the bowel are damaged at Crohn disease
- * all of layers
 - mucus
 - submucous and muscle
 - submucous
 - muscle
2439. What localization of ulcer is most characteristic for the patients of elderly and senile age
- * cardial department of stomach
 - overhead third of gullet
 - lower third of gullet
 - bulb of duodewnum
 - small curvature
2440. What medicines is used for increasing the frequency of defecation ?
- * Prozerin.
 - Sulfate of magnesium.
 - Immodium.
 - Karbolon.
 - Digestal.
2441. What medicines is used for treatment of unspecific ulcerative colitis?
- * Sulfasalazinum.
 - Ampicillin.
 - Nospanum, papaverini.
 - Aspirine.
 - Furazolidonum.
2442. What method diagnostics hte ulcerous illness most informing
- * esophagogastrroduodenoscopy
 - analysis of excrement on the hidden blood
 - X-ray
 - global analysis of blood
 - research of gastric secretion
2443. What method is it orientation possible to define the volume of hemorrhage on at the acute gastroenteric bleeding?
- On maintenance red corpuscles, haemoglobin, Ht, thrombocytes
 - On blood volume
 - * On an arteriotony, pulse, state of patient

- D. On a globular volume
 - E. On the level of thrombocytes
2444. What method of examination is used to confirm the diagnosis of Crohn disease?
- A. * A biopsy is with histological examination
 - B. CT
 - C. Sciagraphy
 - D. Sonography
 - E. Rectoscopy
2445. What method of operative treatment is used at the I - IV stage of complicated extrasphincteric fistula?
- A. * Ligature method.
 - B. Rizhikh-1.
 - C. Rizhikh-2.
 - D. Gabriel.
 - E. Cutting and suturing of fistula.
2446. What operation is performed at a acute shoe-shaped paraproctitis ?
- A. Opening of abscess with suturing
 - B. Cutting of abscess (by Gabriel)
 - C. * Opening of abscess with the ligature conduction
 - D. Cutting of abscess with shifting of mucus to distal part of rectum
 - E. Conservative treatment
2447. What operation is performed at an anal fissure?
- A. * Cutting of fissure with sphincterotomy.
 - B. Suturing of fissure.
 - C. Operation of Milligan-Morgan.
 - D. Operation of Gabriel.
 - E. Operation of Nobl.
2448. What operation is performed at haemorrhoids complicated by bleeding
- A. * urgent
 - B. planned
 - C. conservative therapy
 - D. physiotherapeutic procedure
 - E. not performed
2449. What operation is performed at haemorrhoids complicated by trombosis
- A. * urgent
 - B. planned
 - C. conservative therapy
 - D. physiotherapeutic procedure
 - E. not performed
2450. What operation is performed at haemorrhoids?
- A. * Operation of Milligan-Morgan.
 - B. Rizhikh-1.
 - C. Rizhikh-2.
 - D. Operation of Gabriel.
 - E. Operation of Blinnichev.
2451. What operation is performed at patient with fissure and polypus?

- A. * Cutting of fissure with polypectomy.
 - B. Cutting of fissure.
 - C. By Milligan-Morgan.
 - D. By Gabriel.
 - E. Operation of Blinnichev.
2452. What operation is performed at rectocoele?
- A. * by Kumel-Zerenin.
 - B. Kenu-Miles.
 - C. Milligan-Morgan.
 - D. Gabriel.
 - E. Operation of Blinnichev.
2453. What operation is performed at the acute subcutaneous paraproctitis?
- A. Opening of abscess with suturing
 - B. * Cutting of abscess (by Gabriel)
 - C. Opening of abscess with the ligature conduction
 - D. Cutting of abscess with shifting of mucus to distal part of rectum
 - E. Conservative treatment
2454. What operation is performed at the Crohn disease?
- A. * A resection of bowel within the limits of healthy tissues.
 - B. Proctocolonectomy.
 - C. Subtotal colectomy.
 - D. Resection of large and small intestine.
 - E. Application of colostomy.
2455. What operation is performed at the extrasphincteric paraproctitis?
- A. Opening of abscess with suturing
 - B. Cutting of abscess (by Gabriel)
 - C. * Opening of abscess with the ligature conduction
 - D. Cutting of abscess with shifting of mucus to distal part of rectum
 - E. Conservative treatment
2456. What operation is performed at the ischiorectal paraproctitis?
- A. Opening of abscess with suturing
 - B. Cutting of abscess (by Gabriel)
 - C. * Opening of abscess with the ligature conduction
 - D. Cutting of abscess with shifting of mucus to distal part of rectum
 - E. Conservative treatment
2457. What operation is performed at the retrorectal paraproctitis?
- A. Opening of abscess with suturing
 - B. Cutting of abscess (by Gabriel)
 - C. * Opening of abscess with the ligature conduction
 - D. Cutting of abscess with shifting of mucus to distal part of rectum
 - E. Conservative treatment
2458. What operation is performed at the transsphincteric paraproctitis?
- A. Cutting of fistula chanal (by Gabriel)
 - B. * Cutting of fistula chanal with the partial suturing of bottom of wound
 - C. Cutting of fistula chanal with the ligature conduction
 - D. Cutting of fistula with shifting of mucus to distal part of rectum
 - E. Conservative treatment

2459. What operation is radical at haemorrhoids?
- A. Suturing of haemorrhoidal nodes
 - B. Operation by Gabriel
 - C. * Operation by Milligan-Morgan
 - D. Sclerotherapy
 - E. Conservative treatment
2460. What operation is used for pararectal fistula?
- A. * Operation of Gabriel.
 - B. Operation of Milligan-Morgan.
 - C. Operation of Gagen-Torn.
 - D. Operation of Nobl.
 - E. A sphincterectomy.
2461. What part of colon is damaged by cancer most often:
- A. * Sigmoid colon
 - B. Caecum
 - C. Ascending part
 - D. Descending part
 - E. Rectum
2462. What part of intestine of most often is a pathological process localized in at Crohn disease?
- A. * Terminal part of small intestine.
 - B. Rectum.
 - C. Ascending part of colon bowel.
 - D. Lumbar part of colon bowel.
 - E. Sigmoid bowel.
2463. What patients with poliposis of colon could has in stool:
- A. Nothing
 - B. * Small amount of blood
 - C. Undigested meal
 - D. Presence of part of polypuses
 - E. Melena
2464. What preparation does behave to blocker H2-retseptors?
- A. * tavegil
 - B. obzidan
 - C. hystdol
 - D. cerucal
 - E. oraza
2465. What preparation does behave to blocker of muscarine receptors of coating cages?
- A. cymetidin
 - B. eglonin
 - C. * gastocepini
 - D. etimsiloli
 - E. vinylin
2466. What preparations, except for other properties, own yet and a bacteriostatic effect on Helicobacter pyloris
- A. * all are transferred preparations
 - B. Almagel

- C. Vinylin
 - D. De-nol
 - E. Claritromycin
2467. What products are recommended in the diet of № 1?
- A. * hen in a steam kind
 - B. pancakes
 - C. raw egg-white
 - D. bread rye fresh
 - E. acute cheeses
2468. What stool has patients with poliposis of colon:
- A. Not changed
 - B. Constipations
 - C. * Diarrhea
 - D. White
 - E. Melena
2469. What syndrome is characteristic for hemorrhagic erosive gastritis?
- A. * ulcerous
 - B. hemorrhagic;
 - C. pain;
 - D. all answers are correct;
 - E. all answers are not correct.
2470. What time urgent operations are executed at acute bleeding
- A. * 6 – 12 hours;
 - B. 6 – 10 hours;
 - C. 6 – 8 hours
 - D. 6 – 14 hours;
 - E. 6 – 20 hours
2471. What triad of symptoms is characteristic for an anal fissure
- A. * pain during defecation, spasm of sphincter, bleeding
 - B. pain before defecation, constipations, bleeding
 - C. diarrhea, bleeding, weight loss
 - D. anaemia, diarrhea, pain
 - E. bleeding, anaemia, diarrhea
2472. What violation of mineral exchange is characteristic for patients with ulcerous illness of stomach and intestine
- A. hypocalcemia
 - B. * hypokaliemia
 - C. Hyponatremia
 - D. Hypercalcinemia
 - E. hyperkaliemia
2473. What volume of blood lost at a unspecific ulcerative colitis does consider complications?
- A. To 50 ml
 - B. 50-100 ml
 - C. 150-200 ml
 - D. 200-300 ml
 - E. * 300 ml and more

2474. When apply Teylor's method at ulcerous illness
- A. * at conservative treatment perforeted ulcers
 - B. at conservative treatment sanguifluous ulcers
 - C. at conservative treatment penetration ulcers
 - D. at conservative treatment malignization ulcers
 - E. at conservative treatment of cicatrical pyloristenosis
2475. Where are anal papilla usually located?
- A. In any area of anal channel
 - B. * Only above and lower from dentata line
 - C. In sygmoid colon
 - D. In any area of rectum
 - E. In perianal region
2476. Which preparation is used for treatment of unspecific ulcerative colitis
- A. * sulfasalasine
 - B. fenolftaleine
 - C. cerucal
 - D. analgin
 - E. ketanov
2477. With the purpose of preventing of anaerobic infection at surgical treatment of paraproctitis is used
- A. * hydrogen peroxide
 - B. furacilini
 - C. iodine solution
 - D. rivanol
 - E. alcohol
2478. Aberrant goiter is:
- A. * The goiter of additional gland
 - B. Dislocation of the goiter
 - C. The goiter with increased function
 - D. The goiter with decreased function
 - E. The goiter with normal function
2479. Among the complication of a postoperative period for thyrotoxicosis is:
- A. * Air embolism
 - B. Cretinism
 - C. Lerishe's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2480. Among the typical complication of a postoperative period for thyrotoxicosis is:
- A. * Thyroid storm
 - B. Cretinism
 - C. Lerishe's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2481. Among the typical complication of a postoperative period for thyrotoxicosis is:
- A. * The damage of laryngeal nerve
 - B. Cretinism
 - C. Lerishe's syndrome

- D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2482. Among the typical complication of a postoperative period for thyrotoxicosis is:
- A. * Asphyxia
 - B. Cretinism
 - C. Leriche's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2483. Among the typical complication of a postoperative period for thyrotoxicosis is:
- A. * Parathyroid tetany
 - B. Cretinism
 - C. Leriche's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2484. Among the typical complication of a postoperative period for thyrotoxicosis is:
- A. * Bleeding
 - B. Cretinism
 - C. Leriche's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2485. Basedow's disease is:
- A. * Thyrotoxicosis
 - B. Wooden thyroiditis
 - C. Purulent thyroiditis
 - D. Autoimmune thyroiditis
 - E. Mixedema
2486. Diffuse goiter with hyperthyroidism is called:
- A. * Grave's disease
 - B. Hashimoto disease
 - C. De Kerven disease
 - D. Riedel's disease
 - E. Raynaud's disease
2487. Diffuse goiter with hyperthyroidism is called:
- A. * Basedow's disease
 - B. Hashimoto disease
 - C. De Kerven disease
 - D. Riedel's disease
 - E. Raynaud's disease
2488. Ectopic goiter is:
- A. * Dislocation of the goiter
 - B. The goiter of additional gland
 - C. The goiter with increased function
 - D. The goiter with decreased function
 - E. The goiter with normal function
2489. For the clinical manifestation of retrosternal is typical:
- A. * Dyspnea

- B. Sleepiness
- C. Hypomnesia
- D. Excessive sweating
- E. Tremor of arms

2490. For the clinical manifestation of retrosternal is typical:

- A. * Hoarseness
- B. Sleepiness
- C. Hypomnesia
- D. Excessive sweating
- E. Tremor of arms

2491. For the clinical manifestation of retrosternal is typical:

- A. * Distended veins of neck
- B. Sleepiness,
- C. Hypomnesia
- D. Excessive sweating
- E. Tremor of arms

2492. For the clinical manifestation of the damage of laryngeal nerve is typical:

- A. * Hoarseness
- B. Diarrhea
- C. Cramps
- D. Fever to 40°C
- E. Anemia

2493. For the clinical manifestation of the damage of laryngeal nerve is typical:

- A. * Aponia
- B. Diarrhea
- C. Cramps
- D. Fever to 40°C
- E. Anemia

2494. For the clinical manifestation of the parathyroid tetany is typical:

- A. * Cramps
- B. Aponia
- C. Diarrhea
- D. Fever to 40°C
- E. Anemia

2495. For the clinical manifestation of thyroid storm is typical:

- A. * Excitement, up to psychosis and coma
- B. Hoarseness
- C. Cramps
- D. Aponia
- E. Anemia

2496. For the clinical manifestation of thyroid storm is typical:

- A. * Tachycardia (pulse rate – 150-200 per minute)
- B. Hoarseness
- C. Cramps
- D. Aponia
- E. Anemia

2497. For the clinical manifestation of thyroid storm is typical:
- A. * Complete arrhythmia
 - B. Hoarseness
 - C. Cramps
 - D. Aphonia
 - E. Anemia
2498. For the clinical manifestation of thyroid storm is typical:
- A. * Fever to 40°C
 - B. Hoarseness
 - C. Cramps
 - D. Aphonia
 - E. Anemia
2499. For the clinical manifestation of thyroid storm is typical:
- A. * Hyperemia of the face, neck, limbs
 - B. Hoarseness
 - C. Cramps
 - D. Aphonia
 - E. Anemia
2500. For the clinical manifestation of thyroid storm is typical:
- A. * Extremely sweating
 - B. Hoarseness
 - C. Cramps
 - D. Aphonia
 - E. Anemia
2501. For the clinical manifestation of thyroid storm is typical:
- A. * Diarrhea
 - B. Hoarseness
 - C. Cramps
 - D. Aphonia
 - E. Anemia
2502. For the laboratory disturbances of Basedow's disease is typical:
- A. * Increased level of triiodothyronine
 - B. Decreased level of triiodothyronine
 - C. Increased level of glucocorticoids
 - D. Decreased level of glucocorticoids
 - E. Decreased level of insulin
2503. For the laboratory disturbances of Basedow's disease is typical:
- A. * Increased level of thyroxine
 - B. Decreased level of triiodothyronine
 - C. Increased level of glucocorticoids
 - D. Decreased level of glucocorticoids
 - E. Decreased level of insulin
2504. For the laboratory disturbances of thyrotoxicosis is typical:
- A. * Increased level of lipid metabolism
 - B. Decreased level of carbohydrate metabolism
 - C. Decreased level of lipid metabolism
 - D. Decreased level of protein metabolism

- E. Decreased level of all kinds of metabolism
2505. For the laboratory disturbances of thyrotoxicosis is typical:
- A. * Increased level of protein metabolism
 - B. Decreased level of carbohydrate metabolism
 - C. Decreased level of lipid metabolism
 - D. Decreased level of protein metabolism
 - E. Decreased level of all kinds of metabolism
2506. For the laboratory disturbances of thyrotoxicosis is typical:
- A. * Increased level of carbohydrate metabolism
 - B. Decreased level of carbohydrate metabolism
 - C. Decreased level of lipid metabolism
 - D. Decreased level of protein metabolism
 - E. Decreased level of all kinds of metabolism
2507. For the thyrotoxicosis is typical:
- A. * Mebius' sign
 - B. Homan's sign
 - C. Lovenberg's sign
 - D. Mondor's sign
 - E. Murphy's sign
2508. For the thyrotoxicosis is typical:
- A. * Graefe's sign
 - B. Homan's sign
 - C. Lovenberg's sign
 - D. Mondor's sign
 - E. Murphy's sign
2509. For the thyrotoxicosis is typical:
- A. * Dalrymple's sign
 - B. Homan's sign
 - C. Lovenberg's sign
 - D. Mondor's sign
 - E. Murphy's sign
2510. For the thyrotoxicosis is typical:
- A. * Kocher's sign
 - B. Homan's sign
 - C. Lovenberg's sign
 - D. Mondor's sign
 - E. Murphy's sign
2511. For thyrotoxicosis is typical:
- A. * Stellwag's sign
 - B. Homan's sign
 - C. Lovenberg's sign
 - D. Mondor's sign
 - E. Murphy's sign
2512. Goiter which localized on the back of the tongue is called:
- A. * Ectopic goiter
 - B. Aberrant goiter

- C. Typical
- D. Presternal
- E. Retrosternal

2513. Goiter which occurs in biogeochemical regions with iodine deficiency in environment is called:

- A. * Endemic goiter
- B. Sporadic goiter
- C. Thyrotoxicosis
- D. Myxedema
- E. Atypical goiter

2514. Goiter which occurs in unendemic regions is called:

- A. * Sporadic goiter
- B. Endemic goiter
- C. Thyrotoxicosis
- D. Myxedema
- E. Atypical goiter

2515. Grave's disease is:

- A. * Thyrotoxicosis
- B. Wooden thyroiditis
- C. Purulent thyroiditis
- D. Autoimmune thyroiditis
- E. Mixedema

2516. How is the sign, which is characterized by a weakness of convergence named by author?

- A. * Mebius' sign
- B. Stellwag's sign
- C. Graefe's sign
- D. Dalrymple's sign
- E. Kocher's sign

2517. How is the sign, which is characterized by a wide palpebral fissure named by author?

- A. * Dalrymple's sign
- B. Mebius' sign
- C. Stellwag's sign
- D. Graefe's sign
- E. Kocher's sign

2518. How is the sign, which is characterized by infrequent winking named by author?

- A. * Stellwag's sign
- B. Graefe's sign
- C. Mebius' sign
- D. Dalrymple's sign
- E. Kocher's sign

2519. How is the sign, which is characterized by retraction of the upper eyelid at prompt change of view named by author?

- A. * Kocher's sign
- B. Dalrymple's sign
- C. Mebius' sign
- D. Stellwag's sign
- E. Graefe's sign

2520. How is the sign, which is characterized by the upper lid lag when the patient looks downward named by author?
- A. * Graefe's sign
 - B. Mebius' sign
 - C. Stellwag's sign
 - D. Dalrymple's sign
 - E. Kocher's sign
2521. In case of euthyroid goiter the patient mainly complains of:
- A. * Neck deformity
 - B. Sleepiness
 - C. Hypomnesia
 - D. Excessive sweating
 - E. Tremor of arms
2522. In case of euthyroid goiter the patient mainly complains of:
- A. * Difficult breathing
 - B. Sleepiness
 - C. Hypomnesia
 - D. Excessive sweating
 - E. Tremor of arms
2523. In case of euthyroid goiter the patient mainly complains of:
- A. * Difficult swallowing
 - B. Sleepiness
 - C. Hypomnesia
 - D. Excessive sweating
 - E. Tremor of arms
2524. In case of euthyroid goiter the patient mainly complains of:
- A. * Sudden attacks of cough
 - B. Sleepiness
 - C. Hypomnesia
 - D. Excessive sweating
 - E. Tremor of arms
2525. In case of hyperthyroid goiter the patient mainly complains of:
- A. * Excessive sweating
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2526. In case of hyperthyroid goiter the patient mainly complains of:
- A. * Irritability
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2527. In case of hyperthyroid goiter the patient mainly complains of:
- A. * Heartbeat
 - B. Leg edemas

- C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2528. In case of hyperthyroid goiter the patient mainly complains of:
- A. * Tremor of arms
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2529. In case of hyperthyroid goiter the patient mainly complains of:
- A. * Sleeplessness
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2530. In case of hyperthyroid goiter the patient mainly complains of:
- A. * Feeling of fever
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2531. In case of hyperthyroid goiter the patient mainly complains of:
- A. * Loss of weight
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2532. In case of hypothyroid goiter the patient mainly complains of:
- A. * Sleepiness
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
2533. In case of hypothyroid goiter the patient mainly complains of:
- A. * General weakness
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
2534. In case of hypothyroid goiter the patient mainly complains of:
- A. * Malaise
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
2535. In case of hypothyroid goiter the patient mainly complains of:

- A. * Hypomnesia
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
2536. In case of hypothyroid goiter the patient mainly complains of:
- A. * Dry skin
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
2537. In case of hypothyroid goiter the patient mainly complains of:
- A. * Constipations
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
2538. In case of hypothyroid goiter the patient mainly complains of:
- A. * Leg edemas
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
2539. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. * Excessive sweating
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2540. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. * Irritability
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2541. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. * Heartbeat
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2542. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. * Tremor of arms
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation

2543. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. * Sleeplessness
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2544. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. * Feeling of fever
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2545. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. * Loss of weight
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2546. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. * Palpitation
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2547. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. * Exophthalmos
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2548. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. * Tremor
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
2549. Intrathoracic localization of goiter is called:
- A. * Ectopic goiter
 - B. Aberrant goiter
 - C. Typical
 - D. Presternal
 - E. Retrosternal
2550. The "woody" goiter is a:
- A. * Riedel's goiter
 - B. Hashimoto's goiter
 - C. De Kerven thyroiditis

- D. Grave's disease
 - E. Basedow's disease
2551. The autoimmune thyroiditis is a:
- A. * Hashimoto's goiter
 - B. De Kerven thyroiditis
 - C. Riedel's goiter
 - D. Grave's disease
 - E. Basedow's disease
2552. The constipation is a clinical manifestation of the patient with:
- A. * Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2553. The Dalrymple's sign is typical for:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2554. The Dalrymple's sign is:
- A. * Wide palpebral fissure
 - B. Infrequent winking
 - C. The upper lid lag when the patient looks downward
 - D. A weakness of convergence
 - E. Retraction of the upper eyelid at prompt change of view
2555. The De Kerven thyroiditis is a:
- A. * Purulent thyroiditis
 - B. Autoimmune thyroiditis
 - C. Fibrous thyroiditis
 - D. Thyrotoxicosis
 - E. Nodular goiter
2556. The development of aphonia in early postoperative period after thyroid surgery is the manifestation of:
- A. * The damage of laryngeal nerve
 - B. Thyroid storm
 - C. Parathyroid tetany
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2557. The development of complete arrhythmia in early postoperative period after thyroid surgery is the manifestation of:
- A. * Thyroid storm
 - B. The damage of laryngeal nerve
 - C. Lerishe's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome

2558. The development of cramps in early postoperative period after thyroid surgery is the manifestation of:
- A. * Parathyroid tetany
 - B. The damage of laryngeal nerve
 - C. Thyroid storm
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2559. The development of excitement, up to psychosis and coma in early postoperative period after thyroid surgery is the manifestation of:
- A. * Thyroid storm
 - B. The damage of laryngeal nerve
 - C. Air embolism
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2560. The development of extremely sweating, diarrhea in early postoperative period after thyroid surgery is the manifestation of:
- A. * Thyroid storm
 - B. The damage of laryngeal nerve
 - C. Parathyroid tetany
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2561. The development of fever to 40°C in early postoperative period after thyroid surgery is the manifestation of:
- A. * Thyroid storm
 - B. The damage of laryngeal nerve
 - C. Lerishe's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2562. The development of hoarseness in early postoperative period after thyroid surgery is the manifestation of:
- A. * The damage of laryngeal nerve
 - B. Thyroid storm
 - C. Parathyroid tetany
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2563. The development of hyperemia of the face, neck, limbs in early postoperative period after thyroid surgery is the manifestation of:
- A. * Thyroid storm
 - B. The damage of laryngeal nerve
 - C. Lerishe's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
2564. The development of tachycardia (pulse rate – 150-200 per minute) in early postoperative period after thyroid surgery is the manifestation of:
- A. * Thyroid storm
 - B. The damage of laryngeal nerve
 - C. Parathyroid tetany
 - D. Adrenal insufficiency

- E. Itsenko-Cushing syndrome
2565. The difficult breathing is a clinical manifestation of the patient with:
- A. * Euthyroid goiter
 - B. Hypothyroidism
 - C. Thyrotoxicosis
 - D. Esophageal achalasia
 - E. Gastric ulcer
2566. The difficult swallowing is a clinical manifestation of the patient with:
- A. * Euthyroid goiter
 - B. Hypothyroidism
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Empyema
2567. The dry skin is a clinical manifestation of the patient with:
- A. * Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2568. The edemas is a clinical manifestation of the patient with:
- A. * Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2569. The excessive sweating is a clinical manifestation of the patient with:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2570. The excessive sweating is a clinical manifestation of the patient with:
- A. * Hyperthyroid goiter
 - B. Hypothyroid goiter
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2571. The exophthalmos is a clinical manifestation of the patient with:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2572. The feeling of fever is a clinical manifestation of the patient with:
- A. * Thyrotoxicosis
 - B. Mixedema

- C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2573. The feeling of fever is a clinical manifestation of the patient with:
- A. * Hyperthyroid goiter
 - B. Hypothyroid goiter
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2574. The fibrous thyroiditis is a:
- A. * Riedel's goiter
 - B. Hashimoto's goiter
 - C. De Kerven thyroiditis
 - D. Grave's disease
 - E. Basedow's disease
2575. The general weakness is a clinical manifestation of the patient with:
- A. * Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2576. The goiter of additional gland is called:
- A. * Aberrant goiter
 - B. Ectopic goiter
 - C. Typical
 - D. Presternal
 - E. Retrosternal
2577. The Graefe's sign is typical for:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2578. The Graefe's sign is:
- A. * The upper lid lag when the patient looks downward
 - B. Infrequent winking
 - C. A weakness of convergence
 - D. Wide palpebral fissure
 - E. Retraction of the upper eyelid at prompt change of view
2579. The Hashimoto's goiter is a:
- A. * Autoimmune thyroiditis
 - B. Fibrous thyroiditis
 - C. Purulent thyroiditis
 - D. Thyrotoxicosis
 - E. Nodular goiter
2580. The heartbeat is a clinical manifestation of the patient with:

- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2581. The heartbeat is a clinical manifestation of the patient with:
- A. * Hyperthyroid goiter
 - B. Hypothyroid goiter
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2582. The hypomnesia is a clinical manifestation of the patient with:
- A. * Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2583. The increased level of carbohydrate metabolism is typical for:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2584. The increased level of lipid metabolism is typical for:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2585. The increased level of protein metabolism is typical for:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2586. The irritability is a clinical manifestation of the patient with:
- A. * Hyperthyroid goiter
 - B. Hypothyroid goiter
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2587. The Kocher's sign is typical for:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum

2588. The Kocher's sign is:
- A. * Retraction of the upper eyelid at prompt change of view
 - B. Wide palpebral fissure
 - C. Infrequent winking
 - D. The upper lid lag when the patient looks downward
 - E. A weakness of convergence
2589. The loss of weight is a clinical manifestation of the patient with:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2590. The loss of weight is a clinical manifestation of the patient with:
- A. * Hyperthyroid goiter
 - B. Hypothyroid goiter
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2591. The malaise is a clinical manifestation of the patient with:
- A. * Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2592. The Mebius' sign is typical for:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2593. The Mebius' sign is:
- A. * A weakness of convergence
 - B. Infrequent winking
 - C. The upper lid lag when the patient looks downward
 - D. Wide palpebral fissure
 - E. Retraction of the upper eyelid at prompt change of view
2594. The neck deformity is a clinical manifestation of the patient with:
- A. * Euthyroid goiter
 - B. Hypothyroidism
 - C. Thyrotoxicosis
 - D. Esophageal achalasia
 - E. Empyema
2595. The palpitation is a clinical manifestation of the patient with:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter

- D. Gastric ulcer
 - E. Esophageal diverticulum
2596. The palpitation is a clinical manifestation of the patient with:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2597. The purulent thyroiditis is a:
- A. * De Kerven thyroiditis
 - B. Hashimoto's goiter
 - C. Riedel's goiter
 - D. Grave's disease
 - E. Basedow's disease
2598. The Riedel's goiter is a:
- A. Woody" goiter
 - B. Autoimmune thyroiditis
 - C. Purulent thyroiditis
 - D. Thyrotoxicosis
 - E. Nodular goiter
2599. The Riedel's goiter is a:
- A. * Fibrous thyroiditis
 - B. Autoimmune thyroiditis
 - C. Purulent thyroiditis
 - D. Thyrotoxicosis
 - E. Nodular goiter
2600. The sleepiness is a clinical manifestation of the patient with:
- A. * Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2601. The Stellwag's sign is typical for:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2602. The Stellwag's sign is:
- A. * Infrequent winking
 - B. The upper lid lag when the patient looks downward
 - C. A weakness of convergence
 - D. Wide palpebral fissure
 - E. Retraction of the upper eyelid at prompt change of view
2603. The subtotal subfascial resection of the thyroid gland is indicated for:
- A. * Goiter of IV-V degree

- B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Goiter with hypothyroidism
2604. The subtotal subfascial resection of the thyroid gland is indicated for:
- A. * Nodular transformation of toxic goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Goiter with hypothyroidism
2605. The subtotal subfascial resection of the thyroid gland is indicated for:
- A. * Thyrotoxicosis
 - B. Obesity
 - C. Leriche's syndrome
 - D. Paget-Shretter's syndrome
 - E. Achalasia
2606. The subtotal subfascial resection of the thyroid gland is indicated for:
- A. * Severe forms of thyrotoxicosis
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Goiter with hypothyroidism
2607. The treatment of de Kerven thyroiditis is a:
- A. * Drainage of suppurative focus
 - B. Glycocorticoids
 - C. Radioactive iodine
 - D. Resection of thyroid gland
 - E. Mercasolil
2608. The treatment of Hashimoto's goiter is a:
- A. * Glycocorticoids
 - B. Drainage of suppurative focus
 - C. Radioactive iodine
 - D. Resection of thyroid gland
 - E. Mercasolil
2609. The treatment of Hashimoto's goiter is a:
- A. * Thyroidectomy
 - B. Drainage of suppurative focus
 - C. Radioactive iodine
 - D. Resection of thyroid gland
 - E. Mercasolil
2610. The treatment of Riedel's goiter is a:
- A. * Thyroidectomy
 - B. Drainage of suppurative focus
 - C. Radioactive iodine
 - D. Resection of thyroid gland
 - E. Mercasolil

2611. The tremor is a clinical manifestation of the patient with:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2612. The tremor of arms is a clinical manifestation of the patient with:
- A. * Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2613. The tremor of arms is a clinical manifestation of the patient with:
- A. * Hyperthyroid goiter
 - B. Hypothyroid goiter
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
2614. What belongs to the I stage of thyrotoxicosis?
- A. * Onset of thyrotoxicosis, slight enlargement of thyroid gland
 - B. Marked sings of thyrotoxicosis, the thyroid is noticeably enlarged in size
 - C. Thyrotoxic lesion of viscera
 - D. Nonreversible dystrophy of organs and systems
 - E. Asymptomatic course
2615. What belongs to the II stage of thyrotoxicosis?
- A. * Marked sings of thyrotoxicosis, the thyroid is noticeably enlarged in size
 - B. Onset of thyrotoxicosis, slight enlargement of thyroid gland
 - C. Thyrotoxic lesion of viscera
 - D. Nonreversible dystrophy of organs and systems
 - E. Asymptomatic course
2616. What belongs to the III stage of thyrotoxicosis?
- A. * Thyrotoxic lesion of viscera
 - B. Marked sings of thyrotoxicosis, the thyroid is noticeably enlarged in size
 - C. Onset of thyrotoxicosis, slight enlargement of thyroid gland
 - D. Nonreversible dystrophy of organs and systems
 - E. Asymptomatic course
2617. What belongs to the IV stage of thyrotoxicosis?
- A. * Nonreversible dystrophy of organs and systems
 - B. Thyrotoxic lesion of viscera
 - C. Marked sings of thyrotoxicosis, the thyroid is noticeably enlarged in size
 - D. Onset of thyrotoxicosis, slight enlargement of thyroid gland
 - E. Asymptomatic course
2618. What complication is characteristic for the goiter?
- A. * Strumitis
 - B. Laringospasm
 - C. Pneumothorax
 - D. Mediastinal emphysema

- E. Atypical goiter
2619. What complication is characteristic for the goiter?
- A. * Hemorrhage into the gland
 - B. Laryngospasm
 - C. Pneumothorax
 - D. Mediastinal emphysema
 - E. Atypical goiter
2620. What complication is characteristic for the goiter?
- A. * Malignancy
 - B. Laryngospasm
 - C. Pneumothorax
 - D. Mediastinal emphysema
 - E. Atypical goiter
2621. What complication is characteristic for the goiter?
- A. * Asphyxia
 - B. Laryngospasm
 - C. Pneumothorax
 - D. Mediastinal emphysema
 - E. Atypical goiter
2622. What diseases should be the thyrotoxicosis differentiated with?
- A. * Rheumatic disease
 - B. Obesity
 - C. Leriche's syndrome
 - D. Paget-Shretter's syndrome
 - E. Achalasia
2623. What diseases should be the thyrotoxicosis differentiated with?
- A. * Chroniosepsis
 - B. Obesity
 - C. Leriche's syndrome
 - D. Paget-Shretter's syndrome
 - E. Achalasia
2624. What diseases should be the thyrotoxicosis differentiated with?
- A. * Diencephalic lesions
 - B. Obesity
 - C. Leriche's syndrome
 - D. Paget-Shretter's syndrome
 - E. Achalasia
2625. What diseases should be the thyrotoxicosis differentiated with?
- A. * Thyroid cancer
 - B. Obesity
 - C. Leriche's syndrome
 - D. Paget-Shretter's syndrome
 - E. Achalasia
2626. What diseases should be the thyrotoxicosis differentiated with?
- A. * Encephalitis
 - B. Obesity

- C. Lerishe's syndrome
 - D. Paget-Shretter's syndrome
 - E. Achalasia
2627. What form of thyrotoxicosis is classified as a mild?
- A. * Pulse rate less than 100 beat/min
 - B. Pulse rate 100-120 beat/min
 - C. Pulse rate 120-140 beat/min
 - D. Pulse rate 140-160 beat/min
 - E. Pulse rate more than 160 beat/min
2628. What form of thyrotoxicosis is classified as a mild?
- A. * Loss weight less than 3-5 kg
 - B. Loss weight 5-8 kg
 - C. Loss weight 8-10 kg
 - D. Loss weight 10-15 kg
 - E. Loss weight exceeds 15 kg
2629. What form of thyrotoxicosis is classified as a mild?
- A. * Increase of basal metabolism to 30 %
 - B. Increase of basal metabolism on 30-50 %
 - C. Increase of basal metabolism more than 50 %
 - D. Decrease of basal metabolism to 30 %
 - E. Decrease of basal metabolism more than 50 %
2630. What form of thyrotoxicosis is classified as a moderate?
- A. * Pulse rate 100-120 beat/min
 - B. Pulse rate less than 100 beat/min
 - C. Pulse rate 120-140 beat/min
 - D. Pulse rate 140-160 beat/min
 - E. Pulse rate more than 160 beat/min
2631. What form of thyrotoxicosis is classified as a moderate?
- A. * Loss weight 5-10 kg
 - B. Exceed of weight more than 1-2 kg
 - C. Exceed of weight more than 3-5 kg
 - D. Loss weight 10-15 kg
 - E. Loss weight exceeds 15 kg
2632. What form of thyrotoxicosis is classified as a moderate?
- A. * Increase of basal metabolism on 30-50 %
 - B. Increase of basal metabolism to 30 %
 - C. Increase of basal metabolism more than 50 %
 - D. Decrease of basal metabolism to 30 %
 - E. Decrease of basal metabolism more than 50 %
2633. What form of thyrotoxicosis is classified as severe?
- A. * Pulse rate more than 120 beat/min
 - B. Pulse rate less than 40 beat/min
 - C. Pulse rate 40-80 beat/min
 - D. Pulse rate 80-100 beat/min
 - E. Pulse rate 100-120 beat/min
2634. What form of thyrotoxicosis is classified as severe?

- A. * Loss weight exceeds 10 kg
 - B. Loss weight less than 1-2 kg
 - C. Loss weight 2-3 kg
 - D. Exceed of weight more than 1-2 kg
 - E. Exceed of weight more than 3-5 kg
2635. What form of thyrotoxicosis is classified as severe?
- A. * Increase of basal metabolism more than 50 %
 - B. Increase of basal metabolism on 30-50 %
 - C. Increase of basal metabolism to 30 %
 - D. Decrease of basal metabolism to 30 %
 - E. Decrease of basal metabolism more than 50 %
2636. What form of thyrotoxicosis is related with the increase of basal metabolism more than 50 %?
- A. * Severe
 - B. Mild
 - C. Moderate
 - D. Subclinic
 - E. Asymptomatic
2637. What form of thyrotoxicosis is related with the increase of basal metabolism on 30-50 %?
- A. * Moderate
 - B. Mild
 - C. Severe
 - D. Subclinic
 - E. Asymptomatic
2638. What form of thyrotoxicosis is related with the increase of basal metabolism to 30 %?
- A. * Mild
 - B. Moderate
 - C. Severe
 - D. Subclinic
 - E. Asymptomatic
2639. What form of thyrotoxicosis is related with the loss weight 5-10 kg?
- A. * Moderate
 - B. Mild
 - C. Severe
 - D. Subclinic
 - E. Asymptomatic
2640. What form of thyrotoxicosis is related with the loss weight less than 3-5 kg?
- A. * Mild
 - B. Moderate
 - C. Severe
 - D. Subclinic
 - E. Asymptomatic
2641. What form of thyrotoxicosis is related with the loss weight more than 10 kg?
- A. * Severe
 - B. Moderate
 - C. Mild
 - D. Subclinic

- E. Asymptomatic
2642. What group of medicines does Lithium carbonate belong to?
- A. * Thyrostatic agents
 - B. Antibiotics
 - C. Anticoagulants
 - D. Antiaggregants
 - E. Vitamines
2643. What group of medicines does Mercasolil belong to?
- A. * Thyrostatic agents
 - B. Antibiotics
 - C. Anticoagulants
 - D. Antiaggregants
 - E. Vitamines
2644. What is the 0 degree of goiter?
- A. * The thyroid gland is not palpated;
 - B. The isthmus of the gland is noticeable during swallowing and could be palpated;
 - C. Entire gland is noticeable during swallowing and could be palpated;
 - D. The enlargement of gland results in evident thickening of neck ("a thick neck");
 - E. The gland considerably enlarged, and sharply deforms neck
2645. What is the cause of thyrotoxicosis?
- A. * Autoimmune disturbances
 - B. Atherosclerotic changes
 - C. Calcium metabolism disturbances
 - D. Renal insufficiency
 - E. Pulmonary emphysema
2646. What is the contributing factor which causes the lung abscess?
- A. * Excessive calcium, deficiency of bromine in environment
 - B. Increased cholesterol, dyslipoproteinemia
 - C. Suprarenal insufficiency
 - D. Rheumatism, endocarditis
 - E. Lack of vitamin C
2647. What is the contributing factor which causes the lung abscess?
- A. * Lack of cobalt, and zinc
 - B. Increased cholesterol, dyslipoproteinemia
 - C. Suprarenal insufficiency
 - D. Rheumatism, endocarditis
 - E. Lack of vitamin C
2648. What is the degree of goiter when entire gland is noticeable during swallowing and could be palpated?
- A. * I
 - B. II
 - C. V
 - D. III
 - E. IV
2649. What is the degree of goiter when the enlargement of gland results in evident thickening of neck ("a thick neck")?

- A. * III
- B. I
- C. V
- D. II
- E. IV

2650. What is the degree of goiter when the enlargement reaches excessive size (goiter of major sizes)?

- A. * V
- B. IV
- C. III
- D. I
- E. II

2651. What is the degree of goiter when the gland considerably enlarged, and sharply deforms neck?

- A. * IV
- B. III
- C. I
- D. V
- E. II

2652. What is the degree of goiter when the isthmus of the gland is noticeable during swallowing and could be palpated?

- A. * I
- B. V
- C. II
- D. III
- E. IV

2653. What is the degree of goiter when the thyroid gland is not palpated?

- A. * 0
- B. II
- C. I
- D. III
- E. IV

2654. What is the endemic goiter characterized by?

- A. * Goiter which occurs in biogeochemical regions with iodine deficiency in environment
- B. Goiter which occurs in unendemic regions
- C. Goiter lesion of both lobes
- D. Goiter of atypical localization
- E. Goiter with changed function

2655. What is the I degree of goiter?

- A. * The isthmus of the gland is noticeable during swallowing and could be palpated;
- B. The thyroid gland is not palpated;
- C. Entire gland is noticeable during swallowing and could be palpated;
- D. The enlargement of gland results in evident thickening of neck ("a thick neck");
- E. The gland considerably enlarged, and sharply deforms neck

2656. What is the I stage of thyrotoxicosis?

- A. * Neurotic

- B. Neurohormonal
 - C. Visceropathic
 - D. Cachectic
 - E. Asymptomatic
2657. What is the II degree of goiter?
- A. * Entire gland is noticeable during swallowing and could be palpated;
 - B. The thyroid gland is not palpated;
 - C. The isthmus of the gland is noticeable during swallowing and could be palpated;
 - D. The enlargement of gland results in evident thickening of neck ("a thick neck");
 - E. The gland considerably enlarged, and sharply deforms neck
2658. What is the II stage of thyrotoxicosis?
- A. * Neurohormonal
 - B. Neurotic
 - C. Visceropathic
 - D. Cachectic
 - E. Asymptomatic
2659. What is the III degree of goiter?
- A. * The enlargement of gland results in evident thickening of neck ("a thick neck");
 - B. The thyroid gland is not palpated;
 - C. The isthmus of the gland is noticeable during swallowing and could be palpated;
 - D. Entire gland is noticeable during swallowing and could be palpated;
 - E. The gland considerably enlarged, and sharply deforms neck
2660. What is the III stage of thyrotoxicosis?
- A. * Visceropathic
 - B. Neurohormonal
 - C. Neurotic
 - D. Cachectic
 - E. Asymptomatic
2661. What is the indication for the conservative treatment of the goiter?
- A. * The goiter of I degree
 - B. The retrosternal ectopy of thyroid gland
 - C. The aberrant goiter
 - D. The goiter of IV degree
 - E. The goiter with secondary hyperthyroidism
2662. What is the indication for the conservative treatment of the goiter?
- A. * The goiter of II degree
 - B. The retrosternal ectopy of thyroid gland
 - C. The aberrant goiter
 - D. The goiter of IV degree
 - E. The goiter with secondary hyperthyroidism
2663. What is the indication for the operative treatment of the goiter?
- A. * Nodular goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter

2664. What is the indication for the operative treatment of the goiter?
- A. * Mixed forms of goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
2665. What is the indication for the operative treatment of the goiter?
- A. * The sings of neck compression by goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
2666. What is the indication for the operative treatment of the goiter?
- A. * The goiter with secondary hyperthyroidism
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
2667. What is the indication for the operative treatment of the goiter?
- A. * The goiter with suspicion on malignancy
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
2668. What is the indication for the operative treatment of the goiter?
- A. * The goiter of additional thyroid glands
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
2669. What is the indication for the operative treatment of the goiter?
- A. * The aberrant goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
2670. What is the indication for the operative treatment of the goiter?
- A. * The intrathoracic goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
2671. What is the indication for the operative treatment of the goiter?
- A. * The retrosternal ectopy of thyroid gland
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree

- E. Uncomplicated hypothyroid goiter
2672. What is the indication for the operative treatment of the goiter?
- A. * The complicated goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
2673. What is the IV degree of goiter?
- A. * The gland considerably enlarged, and sharply deforms neck;
 - B. The enlargement reaches excessive size (goiter of major sizes)
 - C. The isthmus of the gland is noticeable during swallowing and could be palpated;
 - D. Entire gland is noticeable during swallowing and could be palpated;
 - E. The enlargement of gland results in evident thickening of neck ("a thick neck")
2674. What is the IV degree of goiter?
- A. * The enlargement reaches excessive size (goiter of major sizes)
 - B. The gland considerably enlarged, and sharply deforms neck;
 - C. The isthmus of the gland is noticeable during swallowing and could be palpated;
 - D. Entire gland is noticeable during swallowing and could be palpated;
 - E. The enlargement of gland results in evident thickening of neck ("a thick neck")
2675. What is the IV stage of thyrotoxicosis?
- A. * Cachectic
 - B. Visceropathic
 - C. Neurohormonal
 - D. Neurotic
 - E. Asymptomatic
2676. What is the main treatment of noncomplicated goiter?
- A. * Conservative treatment
 - B. Segmentectomy
 - C. Lobectomy
 - D. Thyroidectomy
 - E. Hemithyroidectomy
2677. What is the most informative in the diagnostic of thyrotoxicosis?
- A. * Thyroid hormone concentration
 - B. General blood analysis
 - C. X-ray examination with barium
 - D. Coagulogram
 - E. X-ray examination of the neck
2678. What is the most informative in the diagnostic of thyrotoxicosis?
- A. * Serum thyroidstimulating antibodies
 - B. General blood analysis
 - C. X-ray examination with barium
 - D. Coagulogram
 - E. X-ray examination of the neck
2679. What is the most informative in the diagnostic of thyrotoxicosis?
- A. * Detecting of basal metabolism
 - B. General blood analysis

- C. X-ray examination with barium
 - D. Coagulogram
 - E. X-ray examination of the neck
2680. What is the most informative in the diagnostic of thyrotoxicosis?
- A. * Serum iodine-binding globulin concentration
 - B. General blood analysis
 - C. X-ray examination with barium
 - D. Coagulogram
 - E. X-ray examination of the neck
2681. What is the most informative in the diagnostic of thyrotoxicosis?
- A. * Serum thyroidstimulating hormone of hypophysis
 - B. General blood analysis
 - C. X-ray examination with barium
 - D. Coagulogram
 - E. X-ray examination of the neck
2682. What is the predominant factor which causes the goiter?
- A. * Lack of iodine
 - B. Increased cholesterol, dyslipoproteinemia
 - C. Suprarenal insufficiency
 - D. Rheumatism, endocarditis
 - E. Lack of vitamin C
2683. What is the sporadic goiter characterized by?
- A. * Goiter which occurs in unendemic regions
 - B. Goiter which occurs in biogeochemical regions with iodine deficiency in environment
 - C. Goiter lesion of both lobes
 - D. Goiter of atypical localization
 - E. Goiter with changed function
2684. What medicines are used for the treatment of goiter?
- A. * Triiodothyronine
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
2685. What medicines are used for the treatment of goiter?
- A. * Inorganic iodine
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
2686. What medicines are used for the treatment of goiter?
- A. * Thyroidine
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
2687. What medicines are used for the treatment of goiter?

- A. * Thyroxine
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
2688. What medicines belong to thyrostatic agents?
- A. * Lithium carbonate
 - B. Euphyllin
 - C. Vasaprostan
 - D. Nicotine acid
 - E. Dextrin
2689. What medicines belong to thyrostatic agents?
- A. * Mercasolil
 - B. Euphyllin
 - C. Vasaprostan
 - D. Nicotine acid
 - E. Dextrin
2690. What operation is performed in endemic goiter?
- A. * Subfascial resection of thyroid gland
 - B. Segmentectomy
 - C. Lobectomy
 - D. Thyroidectomy
 - E. Hemithyroidectomy
2691. What stage of thyrotoxicosis correlates with the marked signs of thyrotoxicosis and noticeably enlarged thyroid?
- A. * II
 - B. I
 - C. III
 - D. IV
 - E. 0
2692. What stage of thyrotoxicosis correlates with the nonreversible dystrophy of organs and systems?
- A. * IV
 - B. III
 - C. II
 - D. I
 - E. 0
2693. What stage of thyrotoxicosis correlates with the onset of the disease, slight enlargement of thyroid gland?
- A. * I
 - B. II
 - C. III
 - D. IV
 - E. 0
2694. What stage of thyrotoxicosis correlates with the thyrotoxic lesion of viscera?
- A. * III
 - B. II

- C. I
- D. IV
- E. 0

SITUATIONAL TASKS

1. A diarrhea is not obligatory, but possible in acute appendicitis. In what cases diarrhea confirms the inflammation of appendix?
 - A. * In pelvic appendicitis
 - B. On the first day of the disease
 - C. In fever
 - D. In retrocaecal appendicitis
 - E. In retroperitoneal appendicitis

2. A patient complains of a pain in a right iliac area. At first pain appeared in epigastrium, then relocated in a right iliac area. During examination muscular tension of anterior abdominal wall and symptoms of peritoneal irritation are detected in a right iliac area. Leucocytes- 8×10^9 . General urine analysis within norm. Your diagnosis.
 - A. * Acute appendicitis
 - B. Right-side renal colic
 - C. Appendicular infiltrate
 - D. Meckel's diverticulum
 - E. Perforative ulcer

3. A patient complains of a pain in the lower abdomen, mostly on the right side, dizziness. The mentioned signs appeared suddenly, at night. Last menstruation 2 weeks ago. During examination the skin is pale, pulse 92 /min., t -36°C , AP 100/60 mm Hg. The abdomen is slightly tense, painful in lower areas. The signs of peritoneal irritation are insignificant. Hb-98 g/l. Your diagnosis?
 - A. * Ovarian apoplexy
 - B. Renal colic
 - C. Acute appendicitis
 - D. Intestinal obstruction
 - E. Bleeding gastric ulcer

4. A patient was operated 9 days ago for destructive appendicitis with pelvic position. As a complication – the abscess of Douglas space was developed. At digital rectal examination the infiltrate was detected with softening in center. Tactic of surgeon?
 - A. * Punction of the abscess with draining
 - B. Relaparotomy, draining of the abscess
 - C. Presacral antibiotic-novocaine blockade
 - D. Warm small enemas, suppositories with antibiotics
 - E. Electrophoresis with antibiotics on abdomen

5. A patient was operated for acute appendicitis. The condition deteriorated. An abdominal pain appeared, a temperature rose to 39°C . The signs of peritoneal irritation are absent. A jaundice joined. What complication is need to think about?
 - A. * Pylephlebitis
 - B. Diffuse peritonitis
 - C. Subphrenic abscess
 - D. Cholecystitis
 - E. Appendicular infiltrate

6. Among the ways of penetration of infection in appendix in acute appendicitis the most frequent is enterogenic. What microorganisms are revealed more frequent?
- * E. Colli
 - Staphylococci
 - Streptococci
 - Bacteroids
 - Koch's mycobacterii
7. During the operation for acute appendicitis, you revealed a dense appendicular infiltrate. What is your tactic?
- * To close the wound of the abdominal wall and prescribe antibiotics and local cold
 - Under general anesthesia perform a median laparotomy and appendectomy
 - To mobilize the appendix from inflammatory infiltrate and perform appendectomy
 - Perform disclosure and drainage of the infiltrate
 - All the answers wrong
8. For the acute appendicitis, complicated by appendicular infiltrate, in contrast to the tumour of caecum, is characteristic:
- * Tendency to diminishing of the tumour in the process of supervision
 - Long-term anamnesis
 - Excretion of blood from rectum
 - Curvassier's sign
 - Frequent partial intestinal obstruction in anamnesis
9. For the differential diagnostics of acute appendicitis with the urology diseases is not used
- * Irrigoscopy
 - Urography
 - Cystochromoscopy
 - X-ray of kidneys
 - Urine analysis
10. In patient during the operation for acute destructive appendicitis the appendicular infiltrate was diagnosed. What the further tactic of surgeon?
- * Appendectomy not performed, draining the abdominal cavity
 - Appendectomy not performed, to suit the wound
 - Performed appendectomy
 - Performed a cystostomy
 - To remove the infiltrate
11. In patient who underwent the operation of appendectomy on the 5th day at rectal examination was found the inflammatory infiltrate in small pelvis without the signs of abscessing. Choose the necessary medical tactic:
- * Conservative treatment
 - Punction of infiltrate
 - Punction of infiltrate and draining.
 - Discharging of infiltrate
 - Operative treatment.
12. In the diagnostics of pelvic appendicitis the most valuable is:
- * rectal and vaginal examination
 - laboratory analyses
 - laparocentesis
 - laparoscopy
 - colonoscopy

13. In the patient after appendectomy on the 5th day appeared the hectic fever, leucocytosis. In the depths of the pelvis appeared moderate pain, disuric phenomenon, tenesmi. What additional method of investigation you will begin with to diagnose the complication?
- * A digital rectal examination
 - Cystochromoscopy
 - Repeat tests of blood and urine
 - Rectoromanoscopy
 - Repeat irrigoscopy
14. In the patient on the 7th day after the operation for gangrenous appendicitis, was developed a fever, pain in the rectum, tenesmi, frequent and painful urination. During rectal examination revealed the infiltrate in pelvis. During 3 days after the treatment, which included warm enemas and antibiotics, the patient's condition had not improved. Repeat examination revealed a softening of rectal infiltration. Temperature had hectic nature. What is the treatment?
- * Drainage of pelvic abscess through the rectum
 - Antibiotics, physiotherapy, hyperbaric oxygen therapy
 - Drainage of pelvic abscess through retroperitoneal access
 - Laparotomy, opening abscess
 - Laparoscopic drainage of abscess
15. In the patient was diagnosed the retroperitoneal phlegmon as a complication of acute appendicitis. What is the cause of the phlegmon?
- * Retroperitoneal location of appendix
 - Subhepatic location of appendix
 - Local peritonitis in the right iliac region
 - Medial location of appendix
 - Location of appendix laterally from caecum
16. In the patient, aged 18, on the 7th day after the appendectomy developed a pelvic abscess. What will you do?
- * Drain the abscess through the front wall of the rectum
 - Massive antibiotic therapy
 - Drain the abscess by low-median access and drainage of small pelvis
 - Drain the abscess through the right iliac region
 - Drain the abscess by a right-side extraperitoneal access
17. In the patient, aged 40, on the 2nd day after the appendectomy for gangrenous appendicitis, developed intestinal paresis, fever, appeared pain in the right half of abdomen, enlarged liver and jaundice, signs of peritoneal irritation. What complications of acute appendicitis you can think about?
- * Pylephlebitis
 - Peritonitis
 - Subphrenic abscess
 - Intraintestinal abscess
 - Subhepatic abscess
18. In the patient, aged of 72, 14 hours ago appeared a permanent pain in a right iliac area. For last 2 hours the pain diminished. Acute appendicitis is diagnosed. What morphological form of acute appendicitis would result in diminishing of pain intensity?
- * Gangrenous
 - Phlegmonous
 - Catarrhal
 - Perforative

- E. Empyema of appendix
19. In the patient, on the 7th day after appendectomy was developed a pelvic abscess. What is your tactic?
- A. * Abscess drainage through the front wall of the rectum
 - B. To prescribe a massive doses of antibiotic
 - C. To drain the abscess by low-median access and drain a small pelvis
 - D. To drain the abscess by Volkovych-Dyakonov access
 - E. To drain the abscess by right-side extraperitoneal access
20. In the patient, who was operated for gangrenous appendicitis, on the 2nd day after the operation developed paresis of the intestine, jaundice, appeared fever and pain in the right side of abdomen. No signs of peritoneal irritation. What kind of complication of the disease developed?
- A. * Pylephlebitis
 - B. Subphrenic abscess
 - C. Peritonitis
 - D. Intraintestinal abscess
 - E. Subhepatic abscess
21. Is suspected for the patient's appendix. For the differential diagnosis of acute appendicitis with a perforated ulcer, 12 duodenal ulcer you apply?
- A. * The examination abdominal radiography
 - B. X-ray of gastrointestinal tract, irrigoscopy
 - C. Irrigoscopy, irrigography
 - D. Laparocentesis, colonoscopy
 - E. X-ray of the stomach with barium sulfate
22. On examination of the patient, the therapist suspected acute appendicitis, but is not confident in the diagnosis. The disease began six hours ago. What to do?
- A. * Urgent hospitalization of the patient in the surgical department
 - B. To recommend the surgeon consultation
 - C. Urgently send the patient to the clinic for further laboratory examination
 - D. As for the short time since the beginning of the disease, to recommend conservative treatment. The calm, local cold, antibiotics
 - E. Dynamic observation of patient in outpatient department
23. On the 3rd day after appendectomy you made the diagnosis - the diffuse peritonitis. What is your tactic?
- A. * To perform laparotomy
 - B. To enhance antibacterial therapy
 - C. To prescribe spasmolytics, analgetics
 - D. To perform angiographic examination
 - E. To perform laparoscopy
24. Patient B. was examined by urgent surgeon, who suspected acute appendicitis. The examination was prescribed. Which of the following investigations is the least helpful in the diagnosis of acute appendicitis?
- A. * Laparocentesis
 - B. Laboratory research (especially leukocytes)
 - C. Rectal examination
 - D. Axillary and rectal thermometry
 - E. The clinical examination to determine protective muscular tension.

25. Patient K. has the diagnosis: diffuse purulent peritonitis of appendicular origin. For the patient is indicated:
- A. * All mentioned is correct
 - B. Appendectomy and sanation of the abdominal cavity
 - C. Correction of fluid and electrolyte disorders
 - D. Antibacterial therapy
 - E. Total parenteral nutrition for 1-2 days after operation
26. The patient was diagnosed the diffuse peritonitis of appendicular origin. In this case used:
- A. * All mentioned
 - B. Median laparotomy
 - C. Appendectomy
 - D. Abdominal lavage
 - E. Drainage of the abdominal cavity
27. The patient was operated for acute phlegmonous appendicitis and diffuses peritonitis by means of the access to the right iliac region. On the 20th day after the operation was diagnosed right-side subphrenic abscess. What could cause its occurrence?
- A. * Was not used Fovler's position after the operation
 - B. Was not used Trendelenburg's position after the operation
 - C. Was not used Finsterer's position after the operation
 - D. Was not used Billroth 's position after the operation
 - E. Was not performed the tamponade of abdominal cavity
28. The patient, 76 years old, with myocardial infarction, is suspected for acute destructive appendicitis. What is your tactic?
- A. * Urgent operation
 - B. Monitoring and operation if the peritonitis develops
 - C. Prescription of massive doses of broad-spectrum antibiotics and if this therapy is ineffective – operation
 - D. Operation if the diagnosis confirms by laparoscopy
 - E. All the answers are wrong
29. The patient, aged 76, with concomitant pneumonia, was diagnosed phlegmonous appendicitis. What is your tactic?
- A. * Urgent operation
 - B. Monitoring and operation if the peritonitis develops
 - C. Prescription of massive doses of broad-spectrum antibiotics and if this therapy is ineffective – operation
 - D. Operation if the diagnosis confirms by laparoscopy
 - E. All the answers are wrong
30. The patient, is pregnant for 32 weeks, has stayed in the surgical department for 18 hours. During dynamic observation it is impossible to rule out acute appendicitis. What is your tactic?
- A. * Patient need to undergo the operation
 - B. Continue to observe the patient
 - C. Carry out abdominal ultrasonography
 - D. With gynecologist to perform abortion, and then appendectomy
 - E. To perform laparoscopy and to operate if the diagnosis confirms
31. The patient's T, at the ambulatory reception is suspected for acute appendicitis. What is advisable to do?
- A. * Immediately hospitalization of the patient
 - B. To prescribe spasmolytics and repeat examination of the patient in 4-6 hours

- C. The control of the dynamics of body temperature and leucocytosis for 12-24 hours
 - D. To prescribe the anti-inflammatory therapy and repeat examination on the next day
 - E. Observed the patient ambulatory and hospitalized in case of deterioration
32. The point through which the Volkovich-Dyakonov access is performed located on the line between anterior-superior process of the iliac bone and umbilicus:
- A. * between external and middle third
 - B. between external and internal third
 - C. in the internal third
 - D. in the middle
 - E. in external third
33. The pregnant woman (22 weeks) is delivered in urgent clinic with complaints of abdominal pain. The onset was acute, a day ago. Pain appeared in epigastrium, then in the right half of abdomen. There was a single vomiting. The abdomen painful above the right iliac area. Signs of peritoneal irritation are insignificant. Leucocytosis – 21?10⁹. What is the most probable diagnosis?
- A. * Acute appendicitis
 - B. Toxemia of pregnancy
 - C. Threatened abortion
 - D. Acute pancreatitis
 - E. Mesenteric thrombosis
34. You diagnosed and prescribed conservative treatment of appendicular infiltrate. What are the signs of abscessing of appendicular infiltrate?
- A. * All answers correct
 - B. Maintaining a high hectic temperature
 - C. Restoring or increase of pain
 - D. Signs of peritoneal irritation
 - E. Increase of leukocytosis with a shift to the left, the increase of ESR
35. You diagnosed in patient the acute appendicitis. What method of diagnostic is suitable?
- A. * All mentioned is correct
 - B. Laparoscopy
 - C. Clinical analysis of blood
 - D. Rectal examination
 - E. Thermography
36. You have diagnosed the appendicular infiltrate in the patient. What is the most expedient conservative treatment in first three days?
- A. * Antibiotics
 - B. Analgesics
 - C. U.H.F.-therapy
 - D. The warm on right iliac region
 - E. Parenteral use of proteolytic enzymes
37. You have diagnosed the gangrenous acute appendicitis in the patient. What symptoms are the basic for the diagnose?
- A. * Decrease of pain
 - B. Increase of pain
 - C. A sudden increase of pain in the right iliac region
 - D. Bradycardia
 - E. Mayo-Robson's sign in the right iliac region

38. You have to operate the patient with a typical picture of acute phlegmonous appendicitis. What access for appendectomy is the most suitable in this case?
- * Volkovych-Diakonov's access
 - Low-median laparotomy
 - Right-side pararectal access
 - Right-side transrectal incision
 - Transverse laparotomy above navel
39. You suspect in patient the chronic appendicitis. Which of the following methods of investigation can confirm the diagnosis?
- * Irrigoscopy
 - Colonoscopy
 - Laparocentesis
 - Rectoromanoscopy
 - X-ray of the abdominal cavity
40. You suspect the abscess of Douglas' pouch in the patient. What investigations should be carried out for its diagnosis?
- * A digital rectal examination
 - Rectoromanoscopy
 - Colonoscopy
 - Laparoscopy
 - Laparocentesis
41. You suspected acute appendicitis in patient. Diagnostic program includes:
- * All answers correct
 - Thorough anamnesis
 - To exclude all diseases that can simulate acute abdominal pathology
 - Rectal examination in men and vaginal additional examination in women
 - Laboratory tests
42. You suspected acute appendicitis. For the differential diagnosis of acute appendicitis from the right-side renal colic you apply:
- * Prescription of spasmolytics, excretory urography
 - Prescription of narcotic analgetics
 - Laparocentesis, laparoscopy
 - Fluoroscopy gastrointestinal, irrigoscopy
 - Angiography of renal arteries
43. Patient S., aged 56, was admitted to hospital with a diagnosis: acute catarrhal cholecystitis. What symptoms are not typical for this diagnosis?
- nausea
 - symptom Kera
 - * all responses venry
 - lack of muscle tension in the right hypochondrium
 - Musso symptom
44. During surgery at cholelithiasis detected wrinkled gallbladder filled with stones and advanced up to 2.5 cm common bile duct. Patients should
- * make cholecystectomy
 - perform cholecystectomy, then holangiography
 - immediately make an audit of cholecystectomy and duct
 - impose cholecystitis
 - duodenotomy make the audit of the major duodenal papilla

45. Patient A., 43, was admitted to hospital with a diagnosis: chronic cholecystitis calculary. What is the main method of research in this patient?
- A. infusion hography,
 - B. oral cholecystography,
 - C. * SONOGRAPHY
 - D. scanning of the liver,
 - E. computed tomography
46. Patient A., aged 45, was admitted to hospital with jaundice in the background cholelithias. The patient is indicate:
- A. emergency surgery
 - B. conservative treatment
 - C. * emergency operation after the preoperative
 - D. catheterization of the celiac artery
 - E. plasmapheresis
47. Patient A., aged 45, was admitted to hospital with jaundice in the background cholelithias. The patient is shown:
- A. emergency surgery
 - B. conservative treatment
 - C. * there is no right answer
 - D. catheterization of the celiac artery
 - E. plasmapheresis
48. Patient D., 63, operated by acute calculouse cholecystitis. Intraoperatively diagnosed gallbladder with concrements. What operation is indicated the patient?
- A. cholecystostomy
 - B. * cholecystectomy from cervical
 - C. cholecystectomy from the bottom
 - D. cholecystitis-enterovirus anastomosis
 - E. cholecystectomy with drainage choledochitis by Halstead-Pikovsky
49. Patient M., aged 56, was admitted to the hospital with a diagnosis: acute gangrenous cholecystitis. The patient is shown:
- A. conservative treatment
 - B. delayed operation
 - C. decision depends on the age of the patient
 - D. operation with no effect of conservative treatment
 - E. * Emergency operation
50. Patient M., aged 56, was admitted to the hospital with a diagnosis: acute gangrenous cholecystitis. The patient is shown:
- A. conservative treatment
 - B. delayed operation
 - C. decision depends on the age of the patient
 - D. operation with no effect of conservative treatment
 - E. * there is no right answer
51. Patient S., 41, was admitted to hospital with a diagnosis: obstructive jaundice. To diagnose the causes of jaundice is the subject of a more reliable:
- A. oral cholecystography
 - B. intravenous cholecystocholangiography
 - C. * retrograde cholangiography

- D. liver scintigraphy
 - E. direct hepatosplenography
52. Patient S., 42 years old, entered the clinic with a diagnosis: acute calculary cholecystitis. What analgesics is contraindicated?
- A. omnopon
 - B. * morphine hydrochloride
 - C. no-spa
 - D. spazgan
 - E. spazmalgon, baralgin
53. Patient S., 42 years old, entered the clinic with a diagnosis: acute calculary cholecystitis. What analgesics is contraindicated?
- A. omnopon
 - B. * no right answer
 - C. no-spa
 - D. spazgan
 - E. spazmalgon, baralgin
54. Patient S., 42 years old, entered the clinic with a diagnosis: acute calculary cholecystitis. What method is most informativve to clarify the diagnosis in the reception-office?
- A. infusion hology,
 - B. oral cholecystography,
 - C. * SONOGRAPHY
 - D. scanning of the liver,
 - E. computed tomography
55. Patient S., aged 56, was admitted to the hospital with a diagnosis: acute catarrhal cholecystitis. What symptoms are not typical for this diagnosis?
- A. nausea
 - B. Ker's sing
 - C. * Murphy's sing
 - D. absence of muscle tension in the right hypochondrium
 - E. Musso's sing
56. Patient V., aged 45, was admitted to hospital with a diagnosis: chronic cholecystitis. What is a reliable radiological signs of chronic cholecystitis?
- A. weak fluoroscopic shadow of the gall bladder
 - B. sharply increased, not reduced by giving choleretic breakfast
 - C. shadow of the gall bladder
 - D. disconnected" gallbladder
 - E. shadow of suspicion on concretions in the gall bladder at a reduced by 1 / 3 after the administration of choleretic breakfast
57. Patients after cholecystectomy in the immediate postoperative period gradually increases jaundice, these operating cholangiography not indicate the pathology of the bile ducts. The most likely cause of jaundice
- A. serum hepatitis
 - B. common bile duct stone
 - C. hemolytic jaundice
 - D. * operating choledochal injury (ligation)
 - E. all of the above

58. Patients after cholecystectomy in the immediate postoperative period gradually increases jaundice, these operating cholangiography not indicate the pathology of the bile ducts. The most likely cause of jaundice
- A. serum hepatitis
 - B. common bile duct stone
 - C. hemolytic jaundice
 - D. * There is no right answer
 - E. All of the above
59. Patients with suspected calculous cholecystitis for diagnosing stones in the gallbladder indicate:
- A. * abdominal X-ray
 - B. angiography
 - C. Doppler
 - D. celiocentesis
 - E. vulvotsentez
60. Patients with suspected calculous cholecystitis for diagnosing stones in the gallbladder indicate:
- A. * endoscopic retrograde cholangiography
 - B. angiography
 - C. doppler
 - D. laparocentesis
 - E. vulvocentesis
61. Patients with suspected calculous cholecystitis for diagnosing stones in the gallbladder indicate:
- A. * ultrasound abdominal
 - B. angiography
 - C. doppler
 - D. laparocentesis
 - E. vulvocentesis
62. Patients with suspected calculous cholecystitis for diagnosing stones in the gallbladder indicate:
- A. * intravenous cholecystocholangiography
 - B. angiography
 - C. doppler
 - D. laparocentesis
 - E. vulvocentesis
63. The patient admitted to hospital with suspected choledocolithiasis. What method of diagnosis is not used in this case?
- A. ultrasound
 - B. intravenous cholecystocholangiography
 - C. ERPHG
 - D. transhepatic holegraphy
 - E. * hypotonic doudenography
64. The patient admitted to hospital with suspected choledocolithiasis. What method of diagnosis is not used in this case?
- A. ultrasound
 - B. intravenous cholecystocholangiography
 - C. ERPHG
 - D. transhepatic holegraphy
 - E. * all answer are right

65. The patient admitted to hospital with suspected choledocolithiasis. What method of diagnosis is not used in this case?
- ultrasound
 - intravenous cholecystocholangiography
 - ERPHG
 - transhepatic holergraphy
 - * endoscopy
66. The patient K., 50 years old, six months after cholecystectomy performed at the calculouse chronic cholecystitis, again began to appear in the right hypochondrium pain, occasionally accompanied by yellowing of the sclera. Ultrasound examination of the abdominal cavity obvious pathology of the extrahepatic bile duct could not be detected. Which of the following methods is most informative for diagnosis in this case?
- infusion holergraphy,
 - oral cholecystography,
 - * endoscopic retrograde cholangiopancreatography,
 - scanning of the liver,
 - computed tomography
67. The patient K., 50 years old, six months after cholecystectomy performed at the calculouse chronic cholecystitis, again began to appear in the right hypochondrium pain, occasionally accompanied by yellowing of the sclera. Which of the following methods is most informative for diagnosis in this case?
- infusion holergraphy,
 - oral cholecystography,
 - * SONOGRAPHY
 - scanning of the liver,
 - computed tomography
68. The patient was diagnosed during surgery iatrogenic injury extrarenal bile ducts. What operation is indicated?
- closure of the injury duct separate atraumatic suture needle
 - suturing of the duct on the T-shaped drainage
 - closure of the duct on Γ -shaped drainage
 - imposition biliodigestiv anastomosis
 - * any of the above
69. The patient with suspected narrowing of the distal common bile duct for diagnosis you must:
- * endoscopic retrograde cholangiography
 - echocardiography
 - laparocentesis
 - certain fraction of bilirubin
 - definition level of blood flow in truncus coeliacus
70. The patient with suspected narrowing of the distal common bile duct for diagnosis you must:
- * there is no right answer
 - echo kardioskopiyu
 - laparocentesis
 - certain fraction of bilirubin
 - definition level of blood flow in truncus coeliacus
71. Patient R., 67 years old, enrolled in urgent hospital with a diagnosis: acute pancreatitis. What medications is necessary to appoint a patient?
- * Spasmodicals

- B. Venotonics
- C. Prostaglandins
- D. Peripheral vasodilators
- E. Hypnotics

72. Patient P., aged 68, was admitted to hospital with clinical acute pancreatitis. Which complications might arise?
- A. Thyrotoxicosis
 - B. Pyelonephritis
 - C. Wrapping Sigma
 - D. * Enzymatic peritonitis
 - E. Urination disorders
73. At a frequent „fat” chair with disseminations of undigested meat and permanent thirst, it is foremost necessary to think about:
- A. * Chronic pancreatitis
 - B. Chronic duodenitis
 - C. Chronic hepatocholecystitis
 - D. Ulcerous diseases of duodenum
 - E. Hepatocirrhosis
74. How often does the pancreatitis department the general bilious channel pass through the head of pancreas?:
- A. * 80-90 %
 - B. 90-100 %
 - C. 75-85 %
 - D. 50-60 %
 - E. 40-50 %
75. In obedience to classification complications of acute pancreatitis, after etiology and pathogeny, distinguish such complications, except for:
- A. Infectiously inflammatory
 - B. Enzymic
 - C. * Allergic
 - D. Mixed
 - E. Trombogemoragic
76. In operation for acute abdomen intraoperatively revealed a hemorrhagic effusion and foci of fat necrosis in the peritoneum. What kind of illness should think?
- A. rupture of the liver
 - B. * acute pancreatitis
 - C. hollow organ injury
 - D. mesenteric thrombosis
 - E. perforated gastric ulcer
77. In operation for acute abdomen intraoperatively revealed a hemorrhagic effusion and foci of fat necrosis in the peritoneum. What kind of illness should think?
- A. rupture of the liver
 - B. * there is no right answer
 - C. hollow organ injury
 - D. mesenteric thrombosis
 - E. perforated gastric ulcer

78. Name the optimum lines the operative interference concerning a acute pancreatitis after the beginning of disease:
- A. 7-8 days
 - B. 1-3 days
 - C. 1-5 days
 - D. 3-5 days
 - E. * Surgical treatment is not indicate
79. Patient K, aged 45, entered the reception room with suspected acute pancreatitis. What kind of research required to clarify the diagnosis?
- A. * Ultrasound
 - B. CT
 - C. MRI
 - D. Doppler
 - E. Scintigraphy
80. Patient K., aged 39, admitted to hospital with clinical acute pancreatitis. Which analgesic should not be used?
- A. Analgin
 - B. Baralgin
 - C. Ketanov
 - D. * Can all
 - E. Keterolak
81. Patient K., aged 39, admitted to hospital with clinical acute pancreatitis. Which analgesic should not be used?
- A. Analgin
 - B. Baralgin
 - C. Ketanov
 - D. * Morphine
 - E. Keterolak
82. Patient K., aged 45, entered the reception room with suspected acute pancreatitis. What kind of research required to clarify the diagnosis?
- A. * there is no right answer
 - B. CT
 - C. MRI
 - D. Doppler
 - E. Scintigraphy
83. Patient P., aged 68, was admitted to hospital with clinical acute pancreatitis. Which complications might arise?
- A. Thyrotoxicosis
 - B. Pyelonephritis
 - C. Wrapping Sigma
 - D. * Omental abscess
 - E. Urination disorders
84. Patient P., aged 68, was admitted to hospital with clinical acute pancreatitis. Which complications might arise?
- A. Thyrotoxicosis
 - B. Pyelonephritis
 - C. Wrapping Sigma
 - D. * Retroperitoneal phlegmon

E. Urination disorders

85. Patient P., aged 68, was admitted to hospital with clinical acute pancreatitis. Which complications might arise?
- A. Thyrotoxicosis
 - B. Pyelonephritis
 - C. Wrapping Sigma
 - D. * No right answer
 - E. Urination disorders
86. Patient R., 67 years old, enrolled in urgent hospital with a diagnosis: acute pancreatitis. What medications is necessary to appoint a patient?
- A. * Cytostatics
 - B. Venotonics
 - C. Prostaglandins
 - D. Peripheral vasodilators
 - E. Hypnotics
87. Patient S., aged 65, went to urgent hospital with a diagnosis: acute pancreatitis. What medications is necessary to appoint a patient?
- A. * H2 - Blockers
 - B. Venotonics
 - C. prostaglandins
 - D. Peripheral vasodilators
 - E. Hypnotics
88. Patient S., aged 65, went to urgent hospital with a diagnosis: acute pancreatitis. Which disease is necessary to differentiate this pathology?
- A. * Acute cholecystitis
 - B. Thyrotoxicosis
 - C. Thrombophlebitis of subcutaneous veins
 - D. Hernia
 - E. Cystitis
89. Patient S., aged 65, went to urgent hospital with a diagnosis: acute pancreatitis. Which disease is necessary to differentiate this pathology?
- A. * Thrombosis of mesenteric vessels
 - B. Thyrotoxicosis
 - C. Thrombophlebitis of subcutaneous veins
 - D. Hernia
 - E. Cystitis
90. Patient S., aged 65, went to urgent hospital with a diagnosis: acute pancreatitis. Which disease is necessary to differentiate this pathology?
- A. * Perforated ulcer
 - B. Thyrotoxicosis
 - C. Thrombophlebitis of subcutaneous veins
 - D. Hernia
 - E. Cystitis
91. Patient T., age 37, was admitted to hospital with a diagnosis: acute pancreatitis. For the dektoksikatsii patient displayed:
- A. * Plasmapheresis
 - B. Perirenal blockade

- C. Application antisecretion drugs
 - D. Epidural anesthesia
 - E. Using antispasmodics
92. Patient T., age 37, was admitted to hospital with a diagnosis: acute pancreatitis. For the dektoksikatsii patient displayed:
- A. * Lymphsorbition
 - B. Perirenal blockade
 - C. Application antisecretion drugs
 - D. Epidural anesthesia
 - E. Using antispasmodics
93. Patient with acute pancreatitis revealed a sharp cyanosis of the face. It is a symptom of the author?
- A. * Lagermf's
 - B. Mondor's
 - C. Halstead's
 - D. Gray – Turner's
 - E. Kulen's
94. Patient with acute pancreatitis revealed cyanosis lateral parts of abdominal skin. It is a symptom of the author?
- A. Lagermf's
 - B. Mondor's
 - C. Halstead's
 - D. * Gray – Turner's
 - E. Kulen's
95. Patient with acute pancreatitis revealed cyanosis of skin of the abdomen. It is a symptom of the author?
- A. Lagermf's
 - B. Mondor's
 - C. * Halstead's
 - D. Gray – Turner's
 - E. Kulen's
96. The patient admitted to hospital with a diagnosis: biliary pancreatitis. What type of treatment is shown to the patient.
- A. Conservative treatment in hospital
 - B. Outpatient
 - C. * Surgical treatment
 - D. Observation of the surgeon at home
 - E. Treatment not indicated
97. The patient admitted to hospital with a diagnosis: biliary pancreatitis. What type of treatment is shown to the patient.
- A. Conservative treatment in hospital
 - B. Outpatient
 - C. * No right answer
 - D. Observation of the surgeon at home
 - E. Treatment not indicated
98. The patient after intake of alcohol appeared repeated vomiting, epigastric pain of herpes character. Diagnosis

- A. Mallory-Weiss syndrome
 - B. Gastric ulcer
 - C. bleeding from varices of the esophagus
 - D. Crohn diseases
 - E. * acute pancreatitis
99. The patient after intake of alcohol appeared repeated vomiting, epigastric pain of herpes character. Diagnosis
- A. Mallory-Weiss syndrome
 - B. Gastric ulcer
 - C. bleeding from varices of the esophagus
 - D. Crohn diseases
 - E. * there is no right answer
100. The patient with acute pancreatitis during the study revealed the absence of pulsation of the abdominal aorta in the epigastrium. It is a symptom of the author?
- A. Lagermf's
 - B. Mondor's
 - C. Halstead's
 - D. Gray – Turner's
 - E. * Voskresenky
101. The patient with acute pancreatitis revealed purple spots on the face and body. It is a symptom of the author?
- A. Lagermf's
 - B. * Mondor's
 - C. Halstead's
 - D. Gray – Turner's
 - E. Kulen's
102. The patient with acute pancreatitis showed a yellow color of the skin near the navel. It is a symptom of the author?
- A. Lagermf's
 - B. Mondor's
 - C. Halstead's
 - D. Gray – Turner's
 - E. * Kulen's
103. 3 hours before admission, the patient appeared "stabbing" pain in the epigastric region. After 1 hour epigastric pain had decreased slightly, but the patient notes that there were sharp pains in the right iliac region. What kind of complications of peptic ulcer can think of?
- A. * Perforation of gastric ulcer
 - B. Malignancy ulcers
 - C. Pyloristhenosis
 - D. Ulcer Penetration
 - E. All answers are correct
104. A man 46 years complain for the expressed general weakness, attacks of palpitation, pain in an epigastrium, which arise up in 10-15 minutes after the reception of meal. During 10 years is ill ulcerative disease of stomach. 2 years ago the executed resection of stomach after Bilroth-II. At inspected a stomach is soft. Sickly in an epigastrium and pyloro-duodenal area. What complication most probably did arise up for a patient?
- A. * Dumping is a syndrome
 - B. Cholecystitis

- C. Peptic gastric ulcer
 - D. Chronic pancreatitis
 - E. Gastritis of stump of stomach
105. A patient 76 years old came to the hospital on seventh twenty-four hours from the beginning of disease with complaints about pain in right hypochondrium, weakness, repeated vomiting, temperature up to 38 degrees. At an examination is a general of middle weight. Pallor. An enlarged gall-bladder is palpated in right hypochondrium where tension is examined. What method of treatment?
- A. * Cholecystostomy under sonography control
 - B. Diet therapy
 - C. Conservative treatment
 - D. Spasmolytics
 - E. Analgesics
106. Choose the most frequent reason of relapse of ulcer after an organ-saving operation with vagotomy at the adequate decline of acid production after an operation:
- A. * syndrome of Zollinger-Ellison
 - B. incomplete vagotomy
 - C. duodeno-gastric reflux of bile
 - D. gastritis of the operated stomach
 - E. excessive use of alcohol
107. During an operation for a patient 68 years old concerning an acute destructive cholecystitis certain presence of festering cholangitis. At the revision of choledochus the not found concretions and sign of stenosis duodenal to the nipple. Cholecystectomy is executed. How is it necessary to make off an operation?
- A. * To execute the external catchment of choledochus
 - B. To impose supraduodenal choledochoduodenostomy
 - C. To execute a transduodenal choledochoduodenostomy
 - D. To execute a choledochojejunostomy
 - E. To drain an abdominal cavity
108. During an operation on occasion of acute calculus cholecystitis the extended general biliary channel is founded. After cholecystectomy through stump of cystic duct is performed cholangiography. On X-Ray of hepatic is founded general bile ducts. In the distal part of choledochus a precipice of contrasting matter is with even edges. A contrast does not act in a duodenum. How to estimate data of intraoperative cholangiography?
- A. * Present of stones in the distal part of choledochus
 - B. Stenosis of duodenal papilla
 - C. Cicatrix narrowing of distal part of choledochus
 - D. Cholecystitis
 - E. Tumour of head of pancreas
109. For a 38-year-old patient after carried two years ago back cholecystectomy recommenced attacks of hepatic colic with turning of skin covers yellow. A postcholecystectomy syndrome is diagnosed. What is most frequent reason of this situation?
- A. * Leave during the first operation concretions
 - B. Stenosis papillitis
 - C. Duodenostasis
 - D. Diskinesia of bile ducts
 - E. Cholestasis

110. For a patient the decompensate stenosis of pyloro-bulb area is on a background 10 years of ulcerative anamnesis. In the state of middle weight he acted with complaints about the frequent vomiting and belch rotten. Marks the expressed weakness. Exhausted. After stabilizing of metabolic indexes and general a patient gave a consent to operative treatment. There are endoscopic signs of the expressed gastritis in all parts of stomach. Choose the method of operation :
- A. * a resection of stomach by Bilioth II
 - B. vagotomy is with an operation which drains a stomach
 - C. imposition of gastrostomy by Vitsel
 - D. selective proximal vagotomy
 - E. a fundoplication by Nissen
111. For a patient 45 years, in 2 years after cholecystectomy there were pains in right hypochondrium, icteric and itch of skin, bitter taste in a company. At sonography of choledohus a 1,2 cm, in distal part located stone. What is the diagnosis?
- A. * Choledoholitiasis. Obturative icterus
 - B. Cholangitis. Mechanical icterus
 - C. Acute pancreatitis. Mechanical icterus
 - D. Postcholecystectomy syndrome
 - E. Tumour of head of pancreas. Mechanical icterus
112. For a patient 48 years with a giant gastric ulcer with recrudescence motion (has ulcerative disease during 11 years) a histamine-reflectory an-acidity is founded. What medical tactic?
- A. * Conservative treatment in hospital and further sanatorium-resort treatment
 - B. Stationary treatment
 - C. Anti-ulcerative therapy is before a planned operation
 - D. Urgent operation
 - E. Stationary conservative treatment during 8 weeks
113. For a patient 60 years icterus during 3 weeks, intensity of it began without pain grows. A stomach at palpation is soft. Positive symptom of Kurvuasie. At sonography of bilious ways expansion of gall-bladder is marked and choledohus. What primary cause of these changes.
- A. * Cancer of head of pancreas
 - B. Bile-stone disease
 - C. Chronic pancreatitis
 - D. Infectious hepatitis
 - E. Cancer of liver.
114. For a patient which carried the resection of stomach a year ago, the attacks of weakness, which arose up on an empty stomach or in 15-20 minutes after the reception of meal, appeared. Attacks were accompanied by a muscle weakness, headache, decline of sugar of blood, decline of arteriotony, sometimes by dizziness. What complication did arise up for a patient?
- A. * Hypoglycaemia syndrome
 - B. Food allergy
 - C. Dumping-syndrome
 - D. Postresection asthenia
 - E. Syndrome of small stomach
115. For a patient C., 58 years, increased feed, after will attack pains the icteric of skin and conjunctiva of sclera, discoloured excrement, darkening of urine appeared in right hypochondrium. A stomach is exaggerated, at palpation sickly in right hypochondrium, a enlarged liver is palpated on a 2-3 cm. In blood general bilirubin 90 mmole/L, direct 60 micromole/L. What is the best examination method?
- A. * Retrograde cholangiopancreatography

- B. Intravenous cholegraphy
 - C. Transcutaneous cholegraphy
 - D. Transcutaneous transhepatic cholegraphy
 - E. Sonography of hepatic region
116. For a patient, which carried an operation, resection of stomach, concerning ulcerative disease, there was a relapse (endoscopy data). What reason of relapse?
- A. * all is transferred
 - B. incomplete vagotomy;
 - C. leave at a resection part of antrum;
 - D. economy resection of stomach;
 - E. syndrome of Zollinger-Ellison;
117. For a patient, which carried the resection of stomach for Bilroth-II concerning ulcerative disease of duodenum is marked complaints about a acute weakness, attacks of palpitation, waves of heat to the face and dizziness at the reception of sweet and suckling meal. Deficit of b.w. - 15kr. On X-Ray of stump of stomach of small sizes with evacuation of barium in the extended efferent bowel. What operatively interference does need it was to be before done to the patient?
- A. * SPV with a pyloroplasty
 - B. Jejunogastroplasy
 - C. Resection of stomach by Rou
 - D. Trunk vagotomy
 - E. Resection of stomach
118. For the exhausted man of 42, which 15 years suffers ulcerative disease of duodenum, during the last two weeks the massive vomiting takes place every evening. At X-Ray stenosis of goalkeeper of stomach is founded. The above-mentioned state became complicated by cramps. what complication did arise up for a patient?
- A. * Tetany
 - B. Bleeding
 - C. Perforation
 - D. Penetration
 - E. Malignancy
119. For the patient of 32 after carried cholecystectomy the attacks of hepatic colic, which are accompanied by turning of skin canopies yellow, recommenced in 6 months. At sonography examination the leave concrements of 2 x is founded 1cm in distal part of choledohus. What treatment for a patient will be optimal?
- A. * Endoscopic duodenocholedohoscopy with papillosphincterotomy
 - B. Conservative therapy by spasmolitics
 - C. Lithotripsy
 - D. Choledolithotomy
 - E. Choledohoduodenoanastomosis
120. For the patient of 63, in a year after cholecystectomy with choledoho-duodenal anastomosis, there were pains in right hypohondrium, icterus, temperature, fever, dryness and bitter taste. What is the previous diagnosis?
- A. * Cholangitis
 - B. Acute pancreatitis
 - C. Duodenitis. Mechanical icterus
 - D. Stricture of choledohus
 - E. Hepatitis is with transformation in a cirrhosis

121. In the ward the patient brought in an unconscious state, with periodic bouts of clonic seizures. According to relatives, the patient for many years suffered from a disease of the stomach. Last month the patient had copious vomiting every day, and he lost considerable weight. On examination, the patient exhausted, dehydrated, in the epigastric region has pigmentation, is determined by the splashing. What method of research to clarify the diagnosis shows the patient after stabilization of the state?
- ECG
 - CT
 - MRI
 - * X-ray study of the abdominal cavity with the passage of barium
 - Ultrasound
122. Operative treatment with a duodenal ulcer it is indicated a patient in those cases when: 1. often there are relapses of disease, 2. a disease becomes complicated continuous bleeding, 3. there is pyloro-duodenal stenosis 4. there is a perforation of ulcer, 5. ulcer penetrates in the head of pancreas, giving the frequent intensifying and phenomena of pancreatitis. Choose the best composition:
- * all true.
 - 1,4
 - 2,3
 - 3,4
 - 1,2
123. Patient 57 years, during the last 10 years has a chronic calculus cholecystitis. Intensifying of disease take place 1-2 times on a year. The last attack began 8 days ago. The icteric skin and sclera appeared in 2 days. During sonography of inspection of organs of abdominal region: thickness of wall of gall-bladder up to 5 mm, present concrements 0,5 to 1,0 cm in a diameter. A width of choledohus is a 1,2 cm, in it supraduodenal part a stone is founded up to 1,0 cm. What complication of gallbladder disease did arise up for a patient?
- * Choledoholitis. Mechanical icterus
 - Acute cholangitis
 - Acute calculus cholecystitis
 - Choledoho-duodenal fistula
 - Cancer of bilious ducts
124. Patient of 51, operated a year ago concerning the perforative ulcer of duodenum. Done barrel vagotomy is with excision of ulcer. Complain for periodic appearance of liquid stool, which arises up suddenly (for two three times on twenty-four hours within a week), whereupon normalized independently. Define a diagnosis.
- * Postvagotomy diarrhoea
 - Chronic pancreatitis
 - Dumping is a syndrome
 - Chronic colitis
 - Poliposis of colon
125. Patient S., 27 years old admitted to clinic with the diagnosis: perforated ulcer. What study should be carried out in the first place?
- ECG
 - CT
 - MRI
 - * Survey radiography of the abdominal cavity
 - Ultrasound

126. The patient 32 years, two years ago passed cholecystectomy concerning gallbladder disease. There were many shallow concrements in a gallbladder. During six months the attacks of hepatic colic recurred 3 times. Two days ago back after an attack, turning of skin and sclera appeared yellow. Bilirubin of 90 mmole/L. What examination most effective in diagnose?
- A. * sonography of pancreatoduodenal area
 - B. X-Ray of gastrointestinal tract
 - C. Endoscopy
 - D. Cholangiography
 - E. Angiography
127. The patient of 42 four years ago carried the resection of stomach after Hoffmaister-Finsterer concerning the ulcer of duodenum with penetration in a pancreas. During the last year marks pain in an epigastrium and right hypochondrium. A pain syndrome is accompanied massive vomiting by stagnant content with plenty of bile. After vomiting pain is decreased. The repeated treatment of improvement did not bring. A patient became thin on 12 kg. What is the diagnosis?
- A. * Syndrome of afferent loop
 - B. Tumour of stump of stomach
 - C. Chronic pancreatitis
 - D. Relapse of ulcer
 - E. Peptic ulcer of gastroenteroanastomosis
128. The patient of 62 complains in the presence of icterus, itch of skin, light excrement, wet dark. Objectively: a sclera and skin is icteric. An enlarge, painless gallbladder is palpated. Blood test: general bilirubin of 85 mmol/L. What method of examination more expedient in all to use for clarification of diagnosis?
- A. * Retrograde cholangiopancreatography
 - B. Duodenal sounding
 - C. Survey sciagraphy of organs of abdominal region
 - D. Oral cholecystography
 - E. Cholegraphy
129. The patient of H., 62, acted with complaints about pain in the overhead half of stomach after the food intake, heartburn, nausea, decline of mass of body on 15 kg for a year, constipations. Three to the year that is why operated concerning a perforative gastric ulcer, executed resection of stomach. In a year after an operation pain recommenced in the overhead half of stomach, heartburn, periodically there was vomiting by a meal, the state of patient became worse in course of time. Your previous diagnosis?
- A. * Peptic ulcer of gastroenteroanastomosis
 - B. Syndrome of afferent loop
 - C. Cancer of stump of stomach
 - D. Gastritis of the operated stomach
 - E. Chronic pancreatitis
130. The patient with a history of ulcerative while examining the abdomen indicated the disappearance of liver dullness. What is the diagnosis should be suspected in a patient?
- A. Perforated ulcer
 - B. Malignancy ulcers
 - C. * Ulcer bleeding
 - D. Ulcer Penetration
 - E. All answers are correct
131. The patient with a history of ulcerative with X-ray determined by a deep niche, located on the back wall near the small curvature of the antrum. What diagnoses are in the patient?
- A. Perforated ulcer

- B. Malignancy ulcers
 - C. Ulcer bleeding
 - D. * Penetration ulcers
 - E. All answers are correct
132. The patient, 30 years old, was admitted to the surgical department after 2 hours from the moment of perforation of gastric ulcer. The diagnosis beyond doubt, but the patient categorically refused the operation. Your tactics.
- A. Outpatient
 - B. Forced to operate on a patient
 - C. * No right answer
 - D. Transfer the patient in therapy department
 - E. Translate patient infectious disease clinic
133. The patient, 33 years old, with no ulcer history admitted to the surgical department with the diagnosis: perforated gastric ulcer. In the operation revealed perforation hole 0,5 ? 0,5 cm on the lesser curvature of the stomach, without inflammatory infiltration around. What should be the volume of transactions?
- A. Resection of gastric Billroth I
 - B. Resection of gastric Billroth II
 - C. * No right answer
 - D. The operation is not shown
 - E. Gastrostomy
134. The patient, 34 years old, 6 years ago was silent ulcer perforation duodenum. Two years after this the patient felt well and do not appealed. Then came the pain, typical of peptic diseases. What method of research is the most informative?
- A. ECG
 - B. * ENDOSCOPY
 - C. X-ray
 - D. CT
 - E. MRI
135. The patient, 35 years old, admitted to emergency room, diagnosed a bleeding stomach ulcer. Where the patient must treatment?
- A. Therapeutic department
 - B. Surgery
 - C. * Intensive Care Unit
 - D. Orthopedics
 - E. Day hospital
136. The patient, 35 years old, was admitted to the surgical department with ulcerative gastric hemorrhage. What medications is necessary to appoint a patient?
- A. * Preparations of blood
 - B. Antibiotics
 - C. Vasodilators
 - D. Prostaglandins
 - E. Veintonics
137. The patient, 36 years old, 12 years suffer stomach ulcer Conservative treatment is not effective. What tactics are indicating for treating a patient?
- A. Continue medical treatment
 - B. * No right answer
 - C. Outpatient

- D. Infusion therapy
 - E. Not require treatment
138. The patient, 40 years old, long-suffering with stomach ulcer, said that the last 2 days the pain had become less intense, but at the same time it has been increasing weakness, dizziness. In morning for a few seconds to lose consciousness. On examination, pulse 100 in 1 min. The patient was pale. In the epigastric region is very little pain. No symptoms of irritation of the peritoneum. Where You sent for treatment patient?
- A. Therapeutic department
 - B. Surgery
 - C. * Intensive Care Unit
 - D. Orthopedics
 - E. Day hospital
139. The patient, 42 years old, gastric ulcer in existence for 10 years. After treatment in hospital advanced remission. Three months ago, the patient appeared pain in the lumbar region, sometimes wearing herpes character. What study should be used to refine the diagnosis?
- A. * X-ray study of the digestive tract with barium
 - B. Total blood
 - C. Urinalysis
 - D. Rheovasography
 - E. Doppler
140. The patient, 42 years old, gastric ulcer in existence for 10 years. After treatment in hospital advanced remission. Three months ago, the patient appeared pain in the lumbar region, sometimes wearing herpes character. What study should be used to refine the diagnosis?
- A. * No right answer
 - B. Total blood
 - C. Urinalysis
 - D. Rheovasography
 - E. Doppler
141. The patient, aged 39, suffering from stomach ulcer, recently had a feeling of heaviness in the epigastric region, which is usually only after vomiting. The patient has lost much weight. What method of diagnosis should be used to refine the diagnosis?
- A. ECG
 - B. Ultrasound
 - C. * X-ray study of the abdominal cavity with the passage of barium
 - D. CT
 - E. MRI
142. The patient, aged 48, suffering for years with stomach ulcer, said that the pain had not become dependent on food intake, have become permanent and less intense. Noted weakness, malaise, fatigue. Lost 5 kg. ESR 40 mm / hour. What kind of complications the peptic ulcer can think of?
- A. Perforated ulcer
 - B. * Malignancy ulcers
 - C. Pyloristhenosis
 - D. Ulcer Penetration
 - E. All answers are correct
143. Woman 55 years, complains on pain in right hypochondrium, temperature up to 39C, darkening of colour of urine. Objectively: skin and visible mucous membranes icteric, liver enlarged, dense, sickly at palpation. In the global analysis of blood of increase of ESR,

neutrophilic leukocytosis, shift to the left, increase of level of bilirubin, ALT, AST. Sonography are stones of gall-bladder. What complication did arise up for this patient?

- A. * Cholangitis
- B. Empyema of gall-bladder
- C. Chronic cholecystitis
- D. Acute cholecystitis
- E. Sepsis

144. Woman of 53, three years ago back carried cholecystectomy concerning a acute calculus cholecystitis. After operation already four times were twinges in right hypochondrium, which lasted 6-8 hours, passed after spasmolytics. After the second attack marked turning of skin and sclera yellow. What examination will be most informing for imputing of diagnosis?

- A. * Sonography
- B. X-Ray of stomach
- C. Endoscopy
- D. Cholangiography
- E. Thermography

145. After the clinical and instrumental research you have diagnosed acute intestinal obstruction, and during laparotomy revealed that it is caused by volvulus. The operation is performed after 3 hours of the disease onset. The incarcerated gut is of dark color, peristalsis is absent. What is the most appropriate surgical tactics?

- A. * To perform intestinal detorsion, resection of the incarcerated region with anastomosis
- B. To perform intestinal detorsion with intestinoplication
- C. To perform intestinal detorsion with enterostomy
- D. To perform intestinal detorsion with intubation
- E. To perform intestinal detorsion

146. Female 50 years old, who had been operated for uterine fibroma (hysterectomy), entered with complaints of abdominal pain, vomiting. On the X-ray of abdomen revealed the signs of small bowel obstruction. What is the cause of obstruction?

- A. * Adhesive disease
- B. Strangulated inguinal hernia
- C. Carcinoma of the colon
- D. Cancer of the small intestine
- E. Diverticulitis

147. In patient 18 years old, appeared cramping abdominal pain, vomiting, constipation and gas delay. On abdominal X-ray revealed "Kloiber's cups. What kind of acute abdominal disease can we speak about?

- A. * Intestinal obstruction
- B. Flatulence
- C. Bad preparation of the patient for examination
- D. Enterocolitis
- E. Helminthic invasion

148. In the clinic entered the patient, aged 72, complaining of severe cramping abdominal pain, constipation and gas delay. Was a single vomiting. The disease began 5 hours ago. From anamnesis: last year was suffering from constipation. On examination: skin is pale, pulse - 116/min, AP -110/80 mm Hg. Heart sounds are weak. The tongue is dry. The abdomen is asymmetrical. A marked flatulence in the left iliac region. Positive Sklyarov's, Kivul's signs, "the falling drop sound". Rectal ampoule is empty, enlarged, with reduced sphincter tone. On

X-ray - high Kloiber's cups. During the enema fluid flows back, increasing the pain. What is the primary diagnosis?

- A. * Acute obstructive large intestine obstruction
- B. Acute obstructive small intestinal obstruction
- C. Spastic ileus of large intestine
- D. Paralytic ileus
- E. Abscess of Douglas' pouch

149. In the department of surgery entered the patient who complained of cramping abdominal pain, which appeared suddenly 3 hours ago, repeated vomiting. 6 hours ago ate a pound of walnuts. On examination: abdomen is distended symmetrically, on auscultation - strengthening the peristaltic tones. On X-ray of the abdominal cavity multiple horizontal air-fluid levels (the width of the horizontal level of the fluid is greater than the height of the gas). What is your primary diagnosis?

- A. * Acute obstructive intestinal obstruction
- B. Acute obstructive large intestine obstruction
- C. Acute paralytic intestinal obstruction
- D. Acute large intestine paralytic ileus
- E. Chronic paralytic intestinal obstruction

150. In the patient A., 79 years old, was diagnosed acute intestinal obstruction and concomitant cardiac pathology. Pulse 103/min AP - 95/60 mm. Hg. After stabilization of hemodynamic parameters the patient was taken for operation, where. revealed a volvulus of sigmoid colon. After detorsion the bowel is dark, peristalsis and vascular pulsation is absent. What is the optimal operation should be done in this case?

- A. * Resection of the sigmoid colon with colostomy
- B. Resection of the sigmoid colon with primary anastomosis
- C. Transanal intubation of the colon
- D. Drainage of the abdominal cavity
- E. Colectomy

151. In the patient was diagnosed the 3rd phase of acute intestinal obstruction with the signs of multiple organ failure and lack of volume of circulating fluid to 25 %. Where does the fluid accumulate first of all?

- A. * In the lumen of the intestine
- B. In the abdominal cavity
- C. In the pleural cavity
- D. In the tissues of the body
- E. In the intercellular space

152. In the patient, who underwent the operation for peritonitis of appendicular origin, on the 4th day appeared flatulence, constipation and gas delay. By percussion tympanitis all over the abdomen, by auscultation - peristalsis is absent, pain is not determined. What is the cause for this condition.

- A. * Paralytic ileus
- B. Strangulated ileus
- C. The abscess of abdominal cavity
- D. Pylephlebitis
- E. Thrombosis of mesenteric vessels

153. In the surgical department entered the patient with complaints of sudden cramping pain in the abdomen, its asymmetry, which arose suddenly after a food abuse, delay of stool and gases. By palpation the abdomen is soft, without signs of peritoneal irritation. In the abdominal cavity

in the left half detected the movable, painful, tumor formation, by elastic consistency. What is the primary diagnosis?

- A. * Sigmoid volvulus
- B. Obstipation syndrome
- C. Acute pancreatitis
- D. Stomach tumor
- E. Rectal cancer

154. In the surgical department in urgent way entered the woman 25 years old with the signs of acute intestinal obstruction. From anamnesis: the patient had operation for ovarian the right apoplexy. The last 1,5 years after the operation flatulence and pain constantly bothered the patient. What has caused the intestinal obstruction in the patient.

- A. * Adhesions in the abdominal cavity
- B. Diverticulum of ileum
- C. Dolihosigma
- D. Appendicular infiltrate
- E. Tumor of the colon

155. In the university hospital entered the patient with a diagnosis of intestinal obstruction. From anamnesis: weight loss (10 kg for 3 months), weakness and occasionally blood in the stool. What is the cause of obstruction?

- A. * Colon cancer
- B. Adhesive disease of peritoneum
- C. Helminthic invasion
- D. Ulcerative colitis
- E. Coprosthesis

156. On abdominal X-ray of the patient is determined several sites of enlightenment of hemispheric shape with the clear horizontal level. What causes such X-ray picture?

- A. * Intestinal obstruction
- B. Perforated ulcer
- C. Flatulence
- D. Colon cancer
- E. Acute pancreatitis

157. Patient 43 years old, who had been operated for acute cholecystitis, entered the clinic with complaints of intense cramping abdominal pain, repeated vomiting and absence of stool. AP - 90/60 mm Hg. The abdomen is moderately distended, soft, slightly painful. Sklyarov's sign is positive Shchetkin - Blumberg sign is slightly positive. What is the primary diagnosis?

- A. * Acute adhesive intestinal obstruction
- B. Perforation of malignant tumor of the stomach
- C. Mesenteric thrombosis
- D. Acute pancreatitis
- E. Perforation of colon intestine

158. Patient 55 years complains of severe cramping abdominal pain, nausea, vomiting, constipation and gas delay. Has been ill for 6 hours. Had been operated for traumatic injury of spleen. On examination: pulse 84/min. The tongue is moderately wet. The abdomen distended with asymmetry due to the increase in the left half. Defined the "splashing sound". Peristaltic sounds periodically amplified. On X-ray of the abdominal cavity - Kloiber's cups. What is the primary diagnosis?

- A. * Acute adhesive intestinal obstruction
- B. Obstructive ileus (tumor genesis)
- C. Thrombosis of mesenteric vessels

- D. Ulcerative colitis
 - E. Sigmoid volvulus
159. Patient B, aged 68, entered the University Hospital after 2 days from the onset of the disease with signs of acute intestinal obstruction. On X-ray - high Kloiber's cups. During enema the fluid flows back, increasing the pain. Indicate the level of intestinal obstruction.
- A. * Low large intestine obstruction
 - B. High small intestinal obstruction
 - C. Low small intestinal obstruction
 - D. Obstruction of the initial part of the colon
 - E. Strangulated ileus
160. Patient K., aged 23, was hospitalized with complaints of nausea, vomiting, cramping pain in the right half of the abdomen. Appendectomy in anamnesis. Pulse - 96/min. AP - 110/70 mm Hg. Abdomen distended, asymmetrical due to protrusion of the right half, over which is determined "splashing sound". The peristalsis strengthened. Signs of peritoneal irritation are absent. Rectal examination: sphincter tone maintained, ampoule dilated. Your diagnosis?
- A. * Acute adhesive intestinal obstruction
 - B. Acute obstructive ileus
 - C. Acute pancreatitis
 - D. Acute adnexitis
 - E. Food poisoning
161. Patient M, 66 years old, arrived from the district hospital at 10 o'clock with complaints of severe abdominal pain, nausea, constipation and gas delay. The disease started suddenly, at 4 o'clock in the morning, with strong cramping abdominal pain. After one hour of the onset the patient entered to the district hospital, and after 5 hours transferred to the regional surgical department. After properly preparing the patient underwent the operation the acute intestinal obstruction. After wide laparotomy, the nodule was found out. Intestinal loops in knot of a dark-brown color, peristalsis and vascular pulsation is absent. What kind of acute intestinal obstruction you deal with?
- A. * Strangulated
 - B. Obstructive
 - C. Spastic
 - D. Mixed
 - E. Paralytic
162. Patient M., aged 25, was hospitalized with complaints of nausea, vomiting, cramping pain in the right half of the abdomen. In anamnesis appendectomy. Pulse 96 per minute, AP 110/70 mm Hg. The abdomen is distended, asymmetrical due to protrusion of the right half, where determined a sign of intestinal splash. The peristalsis is strengthened. Signs of peritoneal irritation are absent. Rectal examination: sphincter tone is lowered, ampoule dilated. What is the primary diagnosis?
- A. * Acute adhesive intestinal obstruction
 - B. Acute obstructive ileus
 - C. Acute pancreatitis
 - D. Acute adnexitis
 - E. Food poisoning
163. Patient R. 38 years old, three years ago underwent appendectomy. After eating about 2 hours ago appeared cramping abdominal pain, flatulence, gas delay. On examination: the patient of moderate condition, restless, changing body position, had double-pointed vomiting. The tongue is dry. Pulse - 110/min. The abdomen distended, soft, painful. Rectal examination: the rectum is empty, the walls are soft, not painful. On X-ray: multiple Kloiber's cups,

pneumatization of small intestine. The patient was made a diagnosis: adhesive intestinal obstruction. What, in your opinion, should the treatment start with?

- A. * With conservative treatment (decompression of the stomach, cleansing enemas, analgesic and antispasmodic therapy)
 - B. With immediate operation
 - C. With gastric lavage and subsequent operation
 - D. With enema and subsequent immediate operation
 - E. No measures required (expectant tactics)
164. Patient S., 30 years complains of cramping abdominal pain, nausea, vomiting, delay of stool and gases. Has been ill for 4 hours. A year ago was performed gastric resection for duodenal ulcer. The patient's condition is grave. Pulse -100/min. The tongue is dry. Abdomen distended, asymmetrical, soft. By percussion - tympanitis. By auscultation - intestinal tones are absent. On the X-ray of abdominal cavity - the Kloiber's cups. What is the primary diagnosis?
- A. * Acute adhesive intestinal obstruction
 - B. Strangulated postoperative hernia
 - C. Malignant tumor of small intestine
 - D. Appendicular infiltrate
 - E. Colon cancer
165. The man 40 years old, entered the hospital with complaints of severe spastic abdominal pain, nausea, vomiting by intestinal content, abdominal distention, delay of stool and gases. Has been ill for 4 hours. Pulse 110 beats/min. The tongue is dry and furred. The abdomen distended asymmetrically - increased upper half, soft by palpation, painful. By auscultation determined active peristaltic sounds with a metallic tone, splashing sound, gurgling. What is the diagnosis?
- A. * Acute intestinal obstruction
 - B. Acute destructive pancreatitis
 - C. Acute destructive cholecystitis
 - D. Acute erosive gastritis
 - E. Acute non-specific colitis
166. The patient 18 years old, was hospitalized in a university hospital in urgent way with the signs of acute intestinal obstruction. From anamnesis 1 year ago she was operated for acute destructive appendicitis. Recently bothered abdominal distension and pain. Which of the following etiological factors resulted in intestinal obstruction?
- A. * Adhesions in the abdominal cavity
 - B. Dolihosigma
 - C. Diverticulum of ileum
 - D. Food disorders
 - E. Helminthic invasion
167. The patient 25 years old, complains of cramping abdominal pain, nausea, vomiting. The onset was sudden, 3 hours ago. Pulse 108 beats/min. The abdomen is asymmetric - right iliac region is hollowed. By palpation in the right iliac region dense cylindrical formation which is moderately painful. Rectal examination determined the content, resembling a "raspberry".
Diagnosis?
- A. * Acute intestinal obstruction
 - B. Acute destructive pancreatitis
 - C. Duodenal bleeding ulcer
 - D. Rectal polyp
 - E. Perforated ulcer
168. The patient 32 years old, who had been operated for perforated ulcer complains of intense cramping pain in the abdomen. On examination: skin is pale. PS - 98 per 1 min. AP - 100/70

- mm Hg. The abdomen is asymmetric, tense and painful in the epigastrium and the right half. Positive Valya's sign. By percussion tympanitis, hepatic dullness is preserved. On X-ray: Kloiber's cups, pneumatization of the intestine. What is your primary diagnosis?
- A. * Adhesive intestinal obstruction
 - B. Perforated duodenal ulcer
 - C. Acute destructive cholecystitis
 - D. Acute destructive appendicitis
 - E. Acute pancreatitis
169. The patient 74 years old, complains of the severe cramping pain in the left side of the abdomen, nausea, constipation and gas delay. Has been ill for 8 hours. During the last 20 years is suffering from constipations. Refuses admixtures of mucus and blood in the stool. Pulse - 82/min. The tongue is moderately wet. Abdomen greatly distended, asymmetrical due to the increase of the left half. Determined the splashing sound. On X-ray of the abdominal cavity Kloiber's cups in the left abdomen with a dilatated colon loop over them. On rectal examination the sign Obukhovskiy hospital. What is the primary diagnosis?
- A. * Sigmoid volvulus
 - B. Obstructive ileus (tumor genesis)
 - C. Adhesive ileus
 - D. Thrombosis of mesenteric vessels
 - E. Ulcerative colitis
170. The patient aged 55, complains of acute pain in the epigastric region, frequent vomiting, without any relief, a general weakness. On examination: pale skin, tongue is dry. Pulse rate - 110/min. AP - 80/40 mm Hg. The abdomen is hollowed, soft by palpation, moderately tense in the epigastrium, signs of peritoneal irritation are absent. On X-ray - Kloiber's cups in the left half. Has been ill for a day. What kind of pathology should be suspected?
- A. * High intestinal obstruction
 - B. Large intestine obstruction
 - C. Perforated duodenal ulcer
 - D. Acute pancreatitis
 - E. Acute cholecystitis
171. The patient complains of cramping pain in the upper abdomen, nausea, vomiting. The tongue is wet. The abdomen is soft, moderately tense in the epigastrium. Determined dilated intestinal loop, which peristalses by palpation. By percussion - tympanic sound with a metallic tone. On the X-ray of abdomen - Kloiber's cups. What is the primary diagnosis?
- A. * Acute intestinal obstruction
 - B. Acute pancreatitis
 - C. Food poisoning
 - D. Acute cholecystitis
 - E. Acute gastroenterocolitis
172. The patient entered with complaints of cramping abdominal pain, vomiting, delay of stool and gases. The patient's condition is severe. Pulse - 105 per 1 min. The tongue is dry. Abdomen distended, asymmetrical. By percussion - tympanitis, visible by eye peristalsis. Positive Valya's sign. Shchetkin-Blumberg sign is slightly positive. What is your diagnosis?
- A. * Intestinal obstruction
 - B. Acute pancreatitis
 - C. Mesenteric thrombosis
 - D. Acute cholecystitis
 - E. Acute appendicitis

173. During the operation for acute appendicitis, you revealed a dense appendicular infiltrate. What is your tactic?
- * To close the wound of the abdominal wall and prescribe antibiotics and local cold
 - Under general anesthesia perform a median laparotomy and appendectomy
 - To mobilize the appendix from inflammatory infiltrate and perform appendectomy
 - Perform disclosure and drainage of the infiltrate
 - All the answers wrong
174. In the patient after appendectomy on the 5th day appeared the hectic fever, leucocytosis. In the depths of the pelvis appeared moderate pain, disuric phenomenon, tenesmi. What additional method of investigation you will begin with to diagnose the complication?
- * A digital rectal examination
 - Cystochromoscopy
 - Repeat tests of blood and urine
 - Rectoromanoscopy
 - Repeat irrigoscopy
175. In the patient on the 7th day after the operation for gangrenous appendicitis, was developed a fever, pain in the rectum, tenesmi, frequent and painful urination. During rectal examination revealed the infiltrate in pelvis. During 3 days after the treatment, which included warm enemas and antibiotics, the patient's condition had not improved. Repeat examination revealed a softening of rectal infiltration. Temperature had hectic nature. What is the treatment?
- * Drainage of pelvic abscess through the rectum
 - Antibiotics, physiotherapy, hyperbaric oxygen therapy
 - Drainage of pelvic abscess through retroperitoneal access
 - Laparotomy, opening abscess
 - Laparoscopic drainage of abscess
176. In the patient was diagnosed the retroperitoneal phlegmon as a complication of acute appendicitis. What is the cause of the phlegmon?
- * Retroperitoneal location of appendix
 - Subhepatic location of appendix
 - Local peritonitis in the right iliac region
 - Medial location of appendix
 - Location of appendix laterally from caecum
177. In the patient, aged 18, on the 7th day after the appendectomy developed a pelvic abscess. What will you do?
- * Drain the abscess through the front wall of the rectum
 - Massive antibiotic therapy
 - Drain the abscess by low-median access and drainage of small pelvis
 - Drain the abscess through the right iliac region
 - Drain the abscess by a right-side extraperitoneal access
178. In the patient, aged 40, on the 2nd day after the appendectomy for gangrenous appendicitis, developed intestinal paresis, fever, appeared pain in the right half of abdomen, enlarged liver and jaundice, signs of peritoneal irritation. What complications of acute appendicitis you can think about?
- * Pylephlebitis
 - Peritonitis
 - Subphrenic abscess
 - Intraintestinal abscess
 - Subhepatic abscess

179. In the patient, on the 7th day after appendectomy was developed a pelvic abscess. What is your tactic?
- A. * Abscess drainage through the front wall of the rectum
 - B. To prescribe a massive doses of antibiotic
 - C. To drain the abscess by low-median access and drain a small pelvis
 - D. To drain the abscess by Volkovich-Dyakonov access
 - E. To drain the abscess by right-side extraperitoneal access
180. In the patient, who was operated for gangrenous appendicitis, on the 2nd day after the operation developed paresis of the intestine, jaundice, appeared fever and pain in the right side of abdomen. No signs of peritoneal irritation. What kind of complication of the disease developed?
- A. * Pylephlebitis
 - B. Subphrenic abscess
 - C. Peritonitis
 - D. Intraintestinal abscess
 - E. Subhepatic abscess
181. Is suspected for the patient's appendix. For the differential diagnosis of acute appendicitis with a perforated ulcer, 12 duodenal ulcer you apply?
- A. * The examination abdominal radiography
 - B. X-ray of gastrointestinal tract, irrigoscopy
 - C. Irrigoscopy, irrigography
 - D. Laparocentesis, colonoscopy
 - E. X-ray of the stomach with barium sulfate
182. On examination of the patient, the therapist suspected acute appendicitis, but is not confident in the diagnosis. The disease began six hours ago. What to do?
- A. * Urgent hospitalization of the patient in the surgical department
 - B. To recommend the surgeon consultation
 - C. Urgently send the patient to the clinic for further laboratory examination
 - D. As for the short time since the beginning of the disease, to recommend conservative treatment. The calm, local cold, antibiotics
 - E. Dynamic observation of patient in outpatient department
183. On the 3rd day after appendectomy you made the diagnosis - the diffuse peritonitis. What is your tactic?
- A. * To perform laparotomy
 - B. To enhance antibacterial therapy
 - C. To prescribe spasmolytics, analgetics
 - D. To perform angiographic examination
 - E. To perform laparoscopy
184. Patient after surgery for diffuse peritonitis antibiotics. What is the way the drug is best?
- A. oral
 - B. subcutaneous
 - C. intramuscular
 - D. * intravenous
 - E. intraperitoneal
185. Patient B. was examined by urgent surgeon, who suspected acute appendicitis. The examination was prescribed. Which of the following investigations is the least helpful in the diagnosis of acute appendicitis?
- A. * Laparocentesis

- B. Laboratory research (especially leukocytes)
 - C. Rectal examination
 - D. Axillary and rectal thermometry
 - E. The clinical examination to determine protective muscular tension.
186. Patient D., aged 39, was admitted to the surgical department with the diagnosis: diffuse peritonitis. What does determines the severity of peritonitis?
- A. * No right answer
 - B. Patient weight
 - C. The growth of the patient
 - D. Body mass index
 - E. All true
187. Patient K. has the diagnosis: diffuse purulent peritonitis of appendicular origin. For the patient is indicated:
- A. * All mentioned is correct
 - B. Appendectomy and sanation of the abdominal cavity
 - C. Correction of fluid and electrolyte disorders
 - D. Antibacterial therapy
 - E. Total parenteral nutrition for 1-2 days after operation
188. Patient N., aged 45, was admitted to the surgical department with the diagnosis: biliary peritonitis. Treatment.
- A. * Operative treatment
 - B. Conservative treatment
 - C. Outpatient care
 - D. Treatment is not required
 - E. Fluid management
189. Patient received an abdominal trauma 3 hours ago. Fetched in emergency clinic complaining of acute pain in stomach. Positive symptoms irritation of the peritoneum. What method of diagnosis should be used to refine the diagnosis.
- A. ECG
 - B. rheovasography
 - C. * X-ray of the abdominal cavity
 - D. doppler
 - E. thermometry
190. Patient received an abdominal trauma 3 hours ago. Fetched in emergency clinic complaining of acute pain in stomach. Positive symptoms irritation of the peritoneum. When the review X-ray revealed free gas under the dome of the diaphragm. Installed diagnosis: breaking the body cavity. Treatment.
- A. cold on the stomach
 - B. laparocentesis
 - C. laparoscopy
 - D. * operation
 - E. antibiotic
191. Patient S., aged 35, was admitted to the surgical department with the diagnosis: appendicular peritonitis. Treatment.
- A. * Operative treatment
 - B. Conservative treatment
 - C. Outpatient care
 - D. Treatment is not required

- E. Fluid management
192. Patient S., aged 35, was admitted to the surgical department with the diagnosis: diffuse peritonitis. What determines the severity of peritonitis?
- A. * The degree of intoxication
 - B. Patient weight
 - C. The growth of the patient
 - D. Body mass index
 - E. All true
193. Patient transported to hospital with a diagnosis: sub-diaphragmatic abscess. What tactics of treatment is most correct?
- A. conservative treatment
 - B. extraperitoneal incision and drainage
 - C. laparotomy, dissection, and backfilling the cavity
 - D. * thick needle puncture of an abscess under ultrasound control
 - E. all of the above is true
194. Patient transported to hospital with a diagnosis: subdiaphragmatic abscess. What access to the abscess should be used?
- A. thoracolumbotomy
 - B. lumbotomy
 - C. two-stage transpleural approach
 - D. Fedorov's laparotomy
 - E. * Extrapleural extraperitoneal method
195. Patient transported to hospital with suspected sub-diaphragmatic abscess. What method of research can clarify the diagnosis?
- A. ECG
 - B. doppler
 - C. * ultrasound
 - D. contrast fluoroscopy GIT
 - E. irrigoscopy
196. Patient transported to hospital with suspected sub-diaphragmatic abscess. What method of research can clarify the diagnosis?
- A. ECG
 - B. doppler
 - C. * radiography of the abdominal cavity
 - D. contrast fluoroscopy GIT
 - E. irrigoskopiya
197. Patient transported to hospital with the diagnosis: diffuse peritonitis. Which surgical approach should be used?
- A. Adrectal access right
 - B. Adrectal access to the left
 - C. Access below the navel
 - D. * Median laparotomy
 - E. No right answer
198. Patient 2 hours ago fell from the second floor. His condition is grave. There are signs of diffuse peritonitis. Completed radiography abdomen. Which of the radiological signs confirm the diagnosis of rupture cavity body?
- A. highstand dome of the diaphragm

- B. Kloiber's bowls
 - C. * free gas in the abdominal cavity
 - D. free fluid in the abdominal cavity
 - E. infiltration in the abdominal cavity
199. Patients 2 hours ago fell from the second floor. His condition is grave. There are signs of diffuse peritonitis. What investigation method can eliminate the damage of a hollow organ?
- A. ECG
 - B. rheovasography
 - C. * radiography of the abdominal cavity
 - D. doppler
 - E. thermometry
200. Patients 2 hours ago was hit in the stomach. Fetched in emergency hospital in serious condition with a suspected rupture cavity body. What method of research will clarify the diagnosis?
- A. ECG
 - B. Doppler
 - C. * X-ray abdomen
 - D. contrast fluoroscopy GIT
 - E. irrigoscopy
201. Patients 2 hours ago was hit in the stomach. Fetched in emergency hospital in serious condition with a suspected rupture cavity body. What method of research will clarify the diagnosis?
- A. ECG
 - B. doppler
 - C. * laparocentesis
 - D. contrast fluoroscopy GIT
 - E. irrigoscopy
202. Patients 2 hours ago was hit in the stomach. Fetched in emergency hospital in serious condition. When radiography diagnosed gap cavity body. Your tactics.
- A. cold on the stomach
 - B. laparocentesis
 - C. laparoscopy
 - D. * operation
 - E. antibiotic
203. The patient 47 years old admitted to the clinic with complaints of pain in the right hypochondrium, nausea, vomiting, body temperature, 38.3. Pain in 3 days ago after receiving a fatty meal. Pulse 112 in 1 min. tongue dry. Skin and sclera subicterichny. In the right hypochondrium defined sharply painful tense rounded education 12h8h6 see positive symptoms Ortner, Murphy, Kera. Symptom Shchetkin-Blumberg positive throughout the abdomen. Which research method should be used?
- A. * Ultrasound
 - B. ECG
 - C. Rheovasography
 - D. Doppler
 - E. Thermometry
204. The patient admitted in emergency hospital in serious condition. Pulse 112 per minute., AP - 110 60, T - 35, 1 °C. Installed diagnosis diffuse peritonitis. Which research method should be used to clarify the source of peritonitis?

- A. ECG
 - B. Rheovasography
 - C. * Ultrasound
 - D. Doppler
 - E. Thermometry
205. The patient admitted in emergency hospital in serious condition. Pulse 112 per minute., AP - 110 60., T-35, 1 °C. Installed diagnosis diffuse peritonitis. What treatment is indicated the patient?
- A. laparocentesis
 - B. laparoscopy
 - C. * surgery
 - D. antibiotic
 - E. puncture
206. The patient admitted with blunt abdominal trauma. Examination - positive symptoms irritation of the peritoneum. Suspected damage to internal organs. What method of diagnosis should be used?
- A. angiography
 - B. rheovasography
 - C. * ultrasound
 - D. ECG
 - E. EEG
207. The patient admitted with blunt abdominal trauma. Examination - positive symptoms of irritation of the peritoneum. Suspected damage to internal organs. What method of diagnosis should be used?
- A. * laparocentesis
 - B. angiography
 - C. rheovasography
 - D. ECG
 - E. EEG
208. The patient complains of severe abdominal pain, which occurred suddenly 6 hours ago. Installed diagnosis of peritonitis. Which symptom is most typical for this diagnosis?
- A. temperature rise
 - B. tachycardia
 - C. leukocytosis
 - D. tension of the muscles of the abdominal wall
 - E. * irritation of the peritoneum
209. The patient complains of severe abdominal pain, which occurred suddenly 6 o'clock ago. Installed diagnosis of peritonitis. Which research method should be used to clarify the source of peritonitis?
- A. * Ultrasound
 - B. ECG
 - C. Rheovasography
 - D. Doppler
 - E. Thermometry
210. The patient during surgery revealed fibropurulent peritonitis. What activities should be undertaken?
- A. removal or delimitation source of peritonitis.
 - B. reorganization of the abdominal cavity.

- C. decompression of the intestine.
 - D. drainage of the abdominal cavity.
 - E. * all answers are correct
211. The patient operated on for acute appendicitis at day 4 after surgery developed peritonitis. Your tactics?
- A. Antibiotic
 - B. Assign analgesics
 - C. Laparocentesis
 - D. Laparoscopy
 - E. * Operation
212. The patient operated on for diffuse peritonitis. In the postoperative period appointed metranidazol. With what's aim was appointed the drug?
- A. * removal of anaerobic microflora.
 - B. removal of fungal flora.
 - C. elimination of the aerobic microflora.
 - D. prevention of helminthic infestation.
 - E. prevention of disseminated candidiasis
213. The patient was admitted to the surgical department with suspected diffuse peritonitis. Which diseases should be a differential diagnosis?
- A. hepato-renal syndrome
 - B. * abdominal ischemic syndrome
 - C. adrenogenital syndrome
 - D. Horner's syndrome
 - E. diencephalic syndrome
214. The patient was diagnosed the diffuse peritonitis of appendicular origin. In this case used:
- A. * All mentioned
 - B. Median laparotomy
 - C. Appendectomy
 - D. Abdominal lavage
 - E. Drainage of the abdominal cavity
215. The patient was operated for acute phlegmonous appendicitis and diffuses peritonitis by means of the access to the right iliac region. On the 20th day after the operation was diagnosed right-side subphrenic abscess. What could cause its occurrence?
- A. * Was not used Fovler's position after the operation
 - B. Was not used Trendelenburg's position after the operation
 - C. Was not used Finsterer's position after the operation
 - D. Was not used Billroth 's position after the operation
 - E. Was not performed the tamponade of abdominal cavity
216. The patient, 76 years old, with myocardial infarction, is suspected for acute destructive appendicitis. What is your tactic?
- A. * Urgent operation
 - B. Monitoring and operation if the peritonitis develops
 - C. Prescription of massive doses of broad-spectrum antibiotics and if this therapy is ineffective – operation
 - D. Operation if the diagnosis confirms by laparoscopy
 - E. All the answers are wrong

217. The patient, aged 76, with concomitant pneumonia, was diagnosed phlegmonous appendicitis. What is your tactic?
- A. * Urgent operation
 - B. Monitoring and operation if the peritonitis develops
 - C. Prescription of massive doses of broad-spectrum antibiotics and if this therapy is ineffective – operation
 - D. Operation if the diagnosis confirms by laparoscopy
 - E. All the answers are wrong
218. The patient, is pregnant for 32 weeks, has stayed in the surgical department for 18 hours. During dynamic observation it is impossible to rule out acute appendicitis. What is your tactic?
- A. * Patient need to undergo the operation
 - B. Continue to observe the patient
 - C. Carry out abdominal ultrasonography
 - D. With gynecologist to perform abortion, and then appendectomy
 - E. To perform laparoscopy and to operate if the diagnosis confirms
219. The patient's T, at the ambulatory reception is suspected for acute appendicitis. What is advisable to do?
- A. * Immediately hospitalization of the patient
 - B. To prescribe spasmolytics and repeat examination of the patient in 4-6 hours
 - C. The control of the dynamics of body temperature and leucocytosis for 12-24 hours
 - D. To prescribe the anti-inflammatory therapy and repeat examination on the next day
 - E. Observed the patient ambulatory and hospitalized in case of deterioration
220. You diagnosed and prescribed conservative treatment of appendicular infiltrate. What are the signs of abscessing of appendicular infiltrate?
- A. * All answers correct
 - B. Maintaining a high hectic temperature
 - C. Restoring or increase of pain
 - D. Signs of peritoneal irritation
 - E. Increase of leukocytosis with a shift to the left, the increase of ESR
221. You diagnosed in patient the acute appendicitis. What method of diagnostic is suitable?
- A. * All mentioned is correct
 - B. Laparoscopy
 - C. Clinical analysis of blood
 - D. Rectal examination
 - E. Thermography
222. You have diagnosed the appendicular infiltrate in the patient. What is the most expedient conservative treatment in first three days?
- A. * Antibiotics
 - B. Analgesics
 - C. U.H.F.-therapy
 - D. The warm on right iliac region
 - E. Parenteral use of proteolytic enzymes
223. You have diagnosed the gangrenous acute appendicitis in the patient. What symptoms are the basic for the diagnose?
- A. * Decrease of pain
 - B. Increase of pain
 - C. A sudden increase of pain in the right iliac region
 - D. Bradycardia

- E. Mayo-Robson's sign in the right iliac region
224. You have to operate the patient with a typical picture of acute phlegmonous appendicitis. What access for appendectomy is the most suitable in this case?
- A. * Volkovych-Diakonov's access
 - B. Low-median laparotomy
 - C. Right-side pararectal access
 - D. Right-side transrectal incision
 - E. Transverse laparotomy above navel
225. You suspect in patient the chronic appendicitis. Which of the following methods of investigation can confirm the diagnosis?
- A. * Irrigoscopy
 - B. Colonoscopy
 - C. Laparocentesis
 - D. Rectoromanoscopy
 - E. X-ray of the abdominal cavity
226. You suspect the abscess of Douglas' pouch in the patient. What investigations should be carried out for its diagnosis?
- A. * A digital rectal examination
 - B. Rectoromanoscopy
 - C. Colonoscopy
 - D. Laparoscopy
 - E. Laparocentesis
227. You suspected acute appendicitis in patient. Diagnostic program includes:
- A. * All answers correct
 - B. Thorough anamnesis
 - C. To exclude all diseases that can simulate acute abdominal pathology
 - D. Rectal examination in men and vaginal additional examination in women
 - E. Laboratory tests
228. You suspected acute appendicitis. For the differential diagnosis of acute appendicitis from the right-side renal colic you apply:
- A. * Prescription of spasmolytics, excretory urography
 - B. Prescription of narcotic analgetics
 - C. Laparocentesis, laparoscopy
 - D. Fluoroscopy gastrointestinal, irrigoscopy
 - E. Angiography of renal arteries
229. Patient S., 27 years old admitted to clinic with the diagnosis: perforated ulcer. What study should be carried out in the first place?
- A. ECG
 - B. CT
 - C. MRI
 - D. * Survey radiography of the abdominal cavity
 - E. Ultrasound
230. Patient A., 43, was admitted to hospital with a diagnosis: chronic cholecystitis calculary. What is the main method of research in this patient?
- A. Ainfusion holegraphy,
 - B. oral cholecystography,
 - C. * SONOGRAPHY

- D. scanning of the liver,
 - E. computed tomography
231. Patient A., aged 45, was admitted to hospital with jaundice in the background cholelithias. The patient is indicate:
- A. emergency surgery
 - B. conservative treatment
 - C. * emergency operation after the preoperative
 - D. catheterization of the celiac artery
 - E. plasmapheresis
232. Patient A., aged 45, was admitted to hospital with jaundice in the background cholelithias. The patient is shown:
- A. emergency surgery
 - B. conservative treatment
 - C. * there is no right answer
 - D. catheterization of the celiac artery
 - E. plasmapheresis
233. Patient D., 63, operated by acute calculouse cholecystitis. Intraoperatively diagnosed gallbladder with concrements. What operation is indicated the patient?
- A. cholecystostomy
 - B. * cholecystectomy from cervical
 - C. cholecystectomy from the bottom
 - D. cholecystitis-enterovirus anastomosis
 - E. cholecystectomy with drainage choledochitis by Halstead-Pikovsky
234. Patient D., aged 39, was admitted to the surgical department with the diagnosis: diffuse peritonitis. What does determines the severity of peritonitis?
- A. * No right answer
 - B. Patient weight
 - C. The growth of the patient
 - D. Body mass index
 - E. All true
235. Patient M., aged 56, was admitted to the hospital with a diagnosis: acute gangrenous cholecystitis. The patient is shown:
- A. conservative treatment
 - B. delayed operation
 - C. decision depends on the age of the patient
 - D. operation with no effect of conservative treatment
 - E. * Emergency operation
236. Patient M., aged 56, was admitted to the hospital with a diagnosis: acute gangrenous cholecystitis. The patient is shown:
- A. conservative treatment
 - B. delayed operation
 - C. decision depends on the age of the patient
 - D. operation with no effect of conservative treatment
 - E. * there is no right answer
237. Patient N., aged 45, was admitted to the surgical department with the diagnosis: biliary peritonitis. Treatment.
- A. * Operative treatment

- B. Conservative treatment
 - C. Outpatient care
 - D. Treatment is not required
 - E. Fluid management
238. Patient S., 42 years old, entered the clinic with a diagnosis: acute calculary cholecystitis. What analgesics is contraindicated?
- A. omnopon
 - B. * no right answer
 - C. no-spa
 - D. spazgan
 - E. spasmalgon, baralgin
239. Patient S., aged 35, was admitted to the surgical department with the diagnosis: appendicular peritonitis. Treatment.
- A. * Operative treatment
 - B. Conservative treatment
 - C. Outpatient care
 - D. Treatment is not required
 - E. Fluid management
240. Patient S., aged 35, was admitted to the surgical department with the diagnosis: diffuse peritonitis. What does determines the severity of peritonitis?
- A. * The degree of intoxication
 - B. Patient weight
 - C. The growth of the patient
 - D. Body mass index
 - E. All true
241. Patient S., aged 56, was admitted to the hospital with a diagnosis: acute catarrhal cholecystitis. What symptoms are not typical for this diagnosis?
- A. nausea
 - B. B. Ker's sing
 - C. * Murphy's sing
 - D. absence of muscle tension in the right hypochondrium
 - E. Musso's sing
242. The patient 47 years old admitted to the clinic with complaints of pain in the right hypochondrium, nausea, vomiting, body temperature, 38.3. Pain in 3 days ago after receiving a fatty meal. Pulse 112 in 1 min. tongue dry. Skin and sclera subikterichny. In the right hypochondrium defined sharply painful tense rounded education 12h8h6 see positive symptoms Ortner, Murphy, Kera. Symptom Shchetkin-Blumberg positive throughout the abdomen. Which research method should be used?
- A. * Ultrasound
 - B. ECG
 - C. Rheovasography
 - D. Doppler
 - E. Thermometry
243. The patient admitted in emergency hospital in serious condition. Pulse 112 per minute., AP - 110 60., T-35, 1 °C. Installed diagnosis diffuse peritonitis. What treatment is indicated the patient?
- A. laparocentesis
 - B. laparoscopy

- C. * surgery
 - D. antibiotic
 - E. puncture
244. The patient admitted to hospital with suspected choledocolithiasis. What method of diagnosis is not used in this case?
- A. ultrasound
 - B. intravenous cholecystocholangiography
 - C. ERPHG
 - D. transhepatic holecography
 - E. * hypotonic doudenography
245. The patient admitted to hospital with suspected choledocolithiasis. What method of diagnosis is not used in this case?
- A. ultrasound
 - B. intravenous cholecystocholangiography
 - C. ERPHG
 - D. transhepatic holecography
 - E. * all answer are right
246. The patient admitted to hospital with suspected choledocolithiasis. What method of diagnosis is not used in this case?
- A. ultrasound
 - B. intravenous cholecystocholangiography
 - C. ERPHG
 - D. transhepatic holecography
 - E. * endoscopy
247. The patient complains of severe abdominal pain, which occurred suddenly 6 hours ago. Installed diagnosis of peritonitis. Which symptom is most typical for this diagnosis?
- A. temperature rise
 - B. tachycardia
 - C. leukocytosis
 - D. tension of the muscles of the abdominal wall
 - E. * irritation of the peritoneum
248. The patient complains of severe abdominal pain, which occurred suddenly 6 o'clock ago. Installed diagnosis of peritonitis. Which research method should be used to clarify the source of peritonitis?
- A. * Ultrasound
 - B. ECG
 - C. Rheovasography
 - D. Doppler
 - E. Thermometry
249. The patient with a history of ulcerative with X-ray determined by a deep niche, located on the back wall near the small curvature of the antrum. What diagnoses are in the patient?
- A. Perforated ulcer
 - B. Malignancy ulcers
 - C. Ulcer bleeding
 - D. * Penetration ulcers
 - E. All answers are correct

250. The patient, 34 years old, 6 years ago was silent ulcer perforation duodenum. Two years after this the patient felt well and do not appealed. Then came the pain, typical of peptic diseases. What method of research is the most informative?
- A. ECG
 - B. * ENDOSCOPY
 - C. X-ray
 - D. CT
 - E. MRI
251. The patient, 36 years old, 12 years suffer stomach ulcer Conservative treatment is not effective. What tactics are indicating for treating a patient?
- A. Continue medical treatment
 - B. * No right answer
 - C. Outpatient
 - D. Infusion therapy
 - E. Not require treatment
252. The patient, 36 years old, 12 years suffer stomach ulcer. Conservative treatment is not effective. What tactics are indicating for treating a patient?
- A. Continue medical treatment
 - B. * Surgical treatment
 - C. Outpatient
 - D. Infusion therapy
 - E. Not require treatment
253. The patient, 36 years old, 12 years suffer stomach ulcer. It is treated routinely in the clinic. What method of research is most informative?
- A. ECG
 - B. * ENDOSCOPY
 - C. X-ray
 - D. CT
 - E. MRI
254. The patient, 40 years old, long-suffering with stomach ulcer, said that the last 2 days the pain had become less intense, but at the same time it has been increasing weakness, dizziness. In morning for a few seconds to lose consciousness. On examination, pulse 100 in 1 min. The patient was pale. In the epigastric region is very little pain. No symptoms of irritation of the peritoneum. What complication of peptic ulcer you can suspect?
- A. Perforated ulcer
 - B. Malignancy ulcers
 - C. * Ulcer bleeding
 - D. Ulcer Penetration
 - E. All answers are correct
255. The patient, 42 years old, gastric ulcer in existence for 10 years. After treatment in hospital advanced remission. Three months ago, the patient appeared pain in the lumbar region, sometimes wearing herpes character. What study should be used to refine the diagnosis?
- A. * X-ray study of the digestive tract with barium
 - B. Total blood
 - C. Urinalysis
 - D. Rheovasography
 - E. Doppler

256. The patient, 42 years old, gastric ulcer in existence for 10 years. After treatment in hospital advanced remission. Three months ago, the patient appeared pain in the lumbar region, sometimes wearing herpes character. What study should be used to refine the diagnosis?
- * No right answer
 - Total blood
 - Urinalysis
 - Rheovasography
 - Doppler
257. A man 46 years complain for the expressed general weakness, attacks of palpitation, pain in an epigastrium, which arise up in 10-15 minutes after the reception of meal. During 10 years is ill ulcerative disease of stomach. 2 years ago the executed resection of stomach after Bilroth- 2. At inspected a stomach is soft. Sickly in an epigastrium and pyloro-duodenal area. What complication most probably did arise up for a patient?
- * Dumping is a syndrome
 - Cholecystitis
 - Peptic gastric ulcer
 - Chronic pancreatitis
 - Gastritis of stump of stomach
258. A man 46 years complain for the expressed general weakness, attacks of palpitation, pain in an epigastrium, which arise up in 10-15 minutes after the reception of meal. During 10 years is ill ulcerative disease of stomach. 2 years ago the executed resection of stomach after Bilroth-II. At inspected a stomach is soft. Sickly in an epigastrium and pyloro-duodenal area. What complication most probably did arise up for a patient?
- * Dumping is a syndrome
 - Cholecystitis
 - Peptic gastric ulcer
 - Chronic pancreatitis
 - Gastritis of stump of stomach
259. A patient 76 years acted to the hospital on seventh twenty-four hours from the beginning of disease with complaints about pain in right hypochondrium, weakness, repeated vomiting, temperature up to 38 degrees. At a examination is a general of middle weight. Pallor. A enlarged gall-bladder is palpated in right hypochondrium where tension is examined. What method of treatment?
- * Cholecystostomy under sonography control
 - Diet therapy
 - Conservative treatment
 - Spasmolitics
 - Analgesics
260. Choose the most frequent reason of relapse of ulcer after a organ-saving operation with vagotomy at the adequate decline of acid production after an operation:
- * syndrome of Zollinger-Elisson
 - incomplete vagotomy
 - duodeno-gastric reflux of bile
 - gastritis of the operated stomach
 - excessive use of alcohol
261. During an operation for a patient 68 years concerning a acute destructive cholecystitis certain presence of festering cholangitis. At the revision of choledohus the not found concrements and sign of stenosis duodenal to the nipple. Cholecystectomy is executed. How is it necessary to make off an operation?

- A. * To execute the external catchment of choledohus
 - B. To impose supraduodenal choledohoduodenostomy
 - C. To execute a transduodenal choledohoduodenostomy
 - D. To execute a choledochojejunostomy
 - E. To drain an abdominal cavity
262. During an operation on occasion of acute calculus cholecystitis the extended general bilious channel is founded. After cholecystectomy through stump of cystic duct is performed cholangiography On X-Ray of hepatic is founded general bile ducts. In the distal part of choledohus a precipice of contrasting matter is with even edges. A contrast does not act in a duodenum. How to estimate data of intraoperative cholangiography?
- A. * Present of stones in the distal part of choledohus
 - B. Stenosis of duodenal papilla
 - C. Cicatrice narrowing of distal part of choledohus
 - D. Cholecystitis
 - E. Tumour of head of pancreas
263. For a 38-years-old patient after carried two years ago back cholecystectomy recommenced attacks of hepatic colic with turning of skin covers yellow. A postcholecystectomy syndrome is diagnosed. What is most frequent reason of this situation?
- A. * Leave during the first operation concrements
 - B. Stenosis papillitis
 - C. Duodenostasis
 - D. Diskinesia of bile ducts
 - E. Cholestasis
264. For a patient the decompensate stenosis of pyloro-bulb area is on a background 10 years of ulcerative anamnesis. In the state of middle weight he acted with complaints about the frequent vomiting and belch rotten. Marks the expressed weakness. Exhausted. After stabilizing of metabolic indexes and general a patient gave a consent to operative treatment. There are endoscopic signs of the expressed gastritis in all parts of stomach. Choose the method of operation :
- A. * a resection of stomach by Bilioth II
 - B. vagotomy is with an operation which drains a stomach
 - C. imposition of gastrostomy by Vitsel
 - D. selective proximal vagotomy
 - E. a fundoplication by Nissen
265. For a patient 45 years, in 2 years after cholecystectomy there were pains in right hypochondrium, icteric and itch of skin, bitter taste in a company. At sonography of choledohus a 1,2 cm, in distal part located stone. What is the diagnosis?
- A. * Choledoholitiasis. Obturative icterus
 - B. Cholangitis. Mechanical icterus
 - C. Acute pancreatitis. Mechanical icterus
 - D. Postcholecystectomy syndrome
 - E. Tumour of head of pancreas. Mechanical icterus
266. For a patient 48 years with a giant gastric ulcer with recrudescence motion (has ulcerative disease during 11 years) a histamine-reflectory an-acidity is founded. What medical tactic?
- A. * Conservative treatment in hospital and further sanatorium-resort treatment
 - B. Stationary treatment
 - C. Anti-ulcerative therapy is before a planned operation
 - D. Urgent operation
 - E. Stationary conservative treatment during 8 weeks

267. For a patient 60 years icterus during 3 weeks, intensity of it began without pain grows. A stomach at palpation is soft. Positive symptom of Kurvuasie. At sonography of bilious ways expansion of gall-bladder is marked and choledohus. What primary cause of these changes.
- * Cancer of head of pancreas
 - Bile-stone disease
 - Chronic pancreatitis
 - Infectious hepatitis
 - Cancer of liver.
268. For a patient which carried the resection of stomach a year ago, the attacks of weakness, which arose up on an empty stomach or in 15-20 minutes after the reception of meal, appeared. Attacks were accompanied by a muscle weakness, headache, decline of sugar of blood, decline of arteriotony, sometimes by dizziness. What complication did arise up for a patient?
- * Hypoglycaemia syndrome
 - Food allergy
 - Dumping-syndrome
 - Postresection asthenia
 - Syndrome of small stomach
269. For a patient C., 58 years, increased feed, after will attack pains the icteric of skin and conjunctiva of sclera, discoloured excrement, darkening of urine appeared in right hypochondrium. A stomach is exaggerated, at palpation sickly in right hypochondrium, a enlarged liver is palpated on a 2-3 cm. In blood general bilirubin 90 mmole/L, direct 60 micromole/L. What is the best examination method?
- * Retrograde cholangiopancreatography
 - Intravenous cholegraphy
 - Transcutaneous cholegraphy
 - Transcutaneous transhepatic cholegraphy
 - Sonography of hepatic region
270. For a patient, which carried an operation, resection of stomach, concerning ulcerative disease, there was a relapse (endoscopy data). What reason of relapse?
- * all correct
 - incomplete vagotomy;
 - leave at a resection part of antrum;
 - economy resection of stomach;
 - syndrome of Zollinger-Elisson;
271. For a patient, which carried the resection of stomach for Bilroth-II concerning ulcerative disease of duodenum is marked complaints about a acute weakness, attacks of palpitation, waves of heat to the face and dizziness at the reception of sweet and suckling meal. Deficit of b.w. - 15kr. On X-Ray of stump of stomach of small sizes with evacuation of barium in the extended efferent bowel. What operatively interference does need it was to be before done to the patient?
- SPV with a pyloroplasty
 - * Jejunogastroplasy
 - Resection of stomach by Rou
 - Trunk vagotomy
 - Resection of stomach
272. For the exhausted man of 42, which 15 years suffers ulcerative disease of duodenum, during the last two weeks the massive vomiting takes place every evening. At X-Ray stenosis of

goalkeeper of stomach is founded. The above-mentioned state became complicated by cramps. what complication did arise up for a patient?

- A. * Tetany
- B. Bleeding
- C. Perforation
- D. Penetration
- E. Malignancy

273. For the patient of 32 after carried cholecystectomy the attacks of hepatic colic, which are accompanied by turning of skin canopies yellow, recommenced in 6 months. At sonography examination the leave concrements of 2 x is founded 1cm in distal part of choledohus. What treatment for a patient will be optimal?

- A. * Endoscopic duodenocholedohoscopy with papillosphincterotomy
- B. Conservative therapy by spasmolitics
- C. Lithotripsy
- D. Choledoholithotomy
- E. Choledohoduodenoanastomosis

274. For the patient of 63, in a year after cholecystectomy with choledoho-duodenal anastomosis, there were pains in right hypochondrium, icterus, temperature, fever, dryness and bitter taste. What is the previous diagnosis?

- A. * Cholangitis
- B. Acute pancreatitis
- C. Duodenitis. Mechanical icterus
- D. Stricture of choledohus
- E. Hepatitis is with transformation in a cirrhosis

275. Operative treatment with a duodenal ulcer it is indicated a patient in those cases when: 1. often there are relapses of disease, 2. a disease becomes complicated continuous bleeding, 3. there is pyloro-duodenal stenosis 4. there is a perforation of ulcer, 5. ulcer penetrates in the head of pancreas, giving the frequent intensifying and phenomena of pancreatitis. Choose the best composition:

- A. * all true.
- B. 1,4
- C. 2,3
- D. 3,4
- E. 1,2

276. Patient 57 years, during the last 10 years has a chronic calculus cholecystitis. Intensifying of disease take place 1-2 times on a year. The last attack began 8 days ago. The icteric skin and sclera appeared in 2 days. During sonography of inspection of organs of abdominal region: thickness of wall of gall-bladder up to 5 mm, present concrements 0,5 to 1,0 cm in a diameter. A width of choledohus is a 1,2 cm, in it supraduodenal part a stone is founded up to 1,0 cm. What complication of gallbladder disease did arise up for a patient?

- A. * Choledoholitiasis. Mechanical icterus
- B. Acute cholangitis
- C. Acute calculus cholecystitis
- D. Choledoho-duodenal fistula
- E. Cancer of bilious ducts

277. Patient of 51, operated a year ago concerning the perforative ulcer of duodenum. Done barrel vagotomy is with excision of ulcer. Complain for periodic appearance of liquid stool, which arises up suddenly (for two three times on twenty-four hours within a week), whereupon normalized independently. Define a diagnosis.

- A. * Postvagotomy diarrhoea
 - B. Chronic pancreatitis
 - C. Dumping is a syndrome
 - D. Chronic colitis
 - E. Poliposis of colon
278. The patient 32 years, two years ago passed cholecystectomy concerning gallbladder disease. There were many shallow concrements in a gallbladder. During six months the attacks of hepatic colic recurred 3 times. Two days ago back after an attack, turning of skin and sclera appeared yellow. Bilirubin of 90 mmole/L. What examination most effective in diagnose?
- A. * sonography of pancreatoduodenal area
 - B. X-Ray of gastrointestinal tract
 - C. Endoscopy
 - D. Cholangiography
 - E. Angiography
279. The patient of 42 four years ago carried the resection of stomach after Hoffmaister-Finsterer concerning the ulcer of duodenum with penetration in a pancreas. During the last year marks pain in an epigastrium and right hypochondrium. A pain syndrome is accompanied massive vomiting by stagnant content with plenty of bile. After vomiting pain is decreased. The repeated treatment of improvement did not bring. A patient became thin on 12 kg. What is the diagnosis?
- A. * Syndrome of afferent loop
 - B. Tumour of stump of stomach
 - C. Chronic pancreatitis
 - D. Relapse of ulcer
 - E. Peptic ulcer of gastroenteroanastomosis
280. The patient of 62 complains in the presence of icterus, itch of skin, light excrement, wet dark. Objectively: a sclera and skin is icteric. An enlarge, painless gallbladder is palpated. Blood test: general bilirubin of 85 mmol/L. What method of examination more expedient in all to use for clarification of diagnosis?
- A. * Retrograde cholangiopancreatography
 - B. Duodenal sounding
 - C. Survey sciagraphy of organs of abdominal region
 - D. Oral cholecystography
 - E. Cholegraphy
281. The patient of H., 62, acted with complaints about pain in the overhead half of stomach after the food intake, heartburn, nausea, decline of mass of body on 15 kg for a year, constipations. Three to the year that is why operated concerning a perforative gastric ulcer, executed resection of stomach. In a year after an operation pain recommenced in the overhead half of stomach, heartburn, periodically there was vomiting by a meal, the state of patient became worse in course of time. Your previous diagnosis?
- A. * Peptic ulcer of gastroenteroanastomosis
 - B. Syndrome of afferent loop
 - C. Cancer of stump of stomach
 - D. Gastritis of the operated stomach
 - E. Chronic pancreatitis
282. Woman 55 years, complains on pain in right hypochondrium, temperature up to 39C, darkening of colour of urine. Objectively: skin and visible mucous membranes icteric, liver enlarged, dense, sickly at palpation. In the global analysis of blood of increase of ESR, neutrophilic leukocytosis, shift to the left, increase of level of bilirubin, ALT, AST. Sonography are stones of gall-bladder. What complication did arise up for this patient?

- A. * Cholangitis
 - B. Empyema of gall-bladder
 - C. Chronic cholecystitis
 - D. Acute cholecystitis
 - E. Sepsis
283. Woman of 53, three years ago back carried cholecystectomy concerning a acute calculus cholecystitis. After operation already four times were twinges in right hypochondrium, which lasted 6-8 hours, passed after spasmolitics. After the second attack marked turning of skin and sclera yellow. What examination will be most informing for imputing of diagnosis?
- A. * Sonography
 - B. X-Ray of stomach
 - C. Endoscopy
 - D. Cholangiography
 - E. Thermography
284. Patient S., aged 56, was admitted to hospital with a diagnosis: acute catarrhal cholecystitis. What symptoms are not typical for this diagnosis?
- A. nausea
 - B. symptom Kera
 - C. * all responses venrny
 - D. lack of muscle tension in the right hypochondrium
 - E. Musso symptom
285. During surgery at cholelithiasis detected wrinkled gallbladder filled with stones and advanced up to 2.5 cm common bile duct. Patients should
- A. * make cholecystectomy
 - B. perform cholecystectomy, then holangiography
 - C. immediately make an audit of cholecystectomy and duct
 - D. impose cholecystitis
 - E. duodenotomy make the audit of the major duodenal papilla
286. Patient A., 43, was admitted to hospital with a diagnosis: chronic cholecystitis calculary. What is the main method of research in this patient?
- A. infusion holegraphy,
 - B. oral cholecystography,
 - C. * SONOGRAPHY
 - D. scanning of the liver,
 - E. computed tomography
287. Patient A., aged 45, was admitted to hospital with jaundice in the background cholelithias. The patient is indicate:
- A. emergency surgery
 - B. conservative treatment
 - C. * emergency operation after the preoperative
 - D. catheterization of the celiac artery
 - E. plasmapheresis
288. Patient A., aged 45, was admitted to hospital with jaundice in the background cholelithias. The patient is shown:
- A. emergency surgery
 - B. conservative treatment
 - C. * there is no right answer
 - D. catheterization of the celiac artery

- E. plasmapheresis
289. Patient D., 63, operated by acute calculous cholecystitis. Intraoperatively diagnosed gallbladder with concretions. What operation is indicated the patient?
- A. cholecystostomy
 - B. * cholecystectomy from cervical
 - C. cholecystectomy from the bottom
 - D. cholecystitis-enterovirus anastomosis
 - E. cholecystectomy with drainage choledochitis by Halstead-Pikovsky
290. Patient M., aged 56, was admitted to the hospital with a diagnosis: acute gangrenous cholecystitis. The patient is shown:
- A. conservative treatment
 - B. delayed operation
 - C. decision depends on the age of the patient
 - D. operation with no effect of conservative treatment
 - E. * Emergency operation
291. Patient M., aged 56, was admitted to the hospital with a diagnosis: acute gangrenous cholecystitis. The patient is shown:
- A. conservative treatment
 - B. delayed operation
 - C. decision depends on the age of the patient
 - D. operation with no effect of conservative treatment
 - E. * there is no right answer
292. Patient S., 41, was admitted to hospital with a diagnosis: obstructive jaundice. To diagnose the causes of jaundice is the subject of a more reliable:
- A. oral cholecystography
 - B. intravenous cholecystocholangiography
 - C. * retrograde cholangiography
 - D. liver scintigraphy
 - E. direct hepatosplenography
293. Patient S., 42 years old, entered the clinic with a diagnosis: acute calculary cholecystitis. What analgesics is contraindicated?
- A. omnopon
 - B. * morphine hydrochloride
 - C. no-spa
 - D. spazgan
 - E. spazmalgon, baralgin
294. Patient S., 42 years old, entered the clinic with a diagnosis: acute calculary cholecystitis. What analgesics is contraindicated?
- A. omnopon
 - B. * no right answer
 - C. no-spa
 - D. spazgan
 - E. spazmalgon, baralgin
295. Patient S., 42 years old, entered the clinic with a diagnosis: acute calculary cholecystitis. What method is most informative to clarify the diagnosis in the reception-office?
- A. infusion holecystography,
 - B. oral cholecystography,

- C. * SONOGRAPHY
 - D. scanning of the liver,
 - E. computed tomography
296. Patient S., aged 56, was admitted to the hospital with a diagnosis: acute catarrhal cholecystitis. What symptoms are not typical for this diagnosis?
- A. nausea
 - B. Ker's sign
 - C. * Murphy's sign
 - D. absence of muscle tension in the right hypochondrium
 - E. Musso's sign
297. Patient V., aged 45, was admitted to hospital with a diagnosis: chronic cholecystitis. What is a reliable radiological sign of chronic cholecystitis?
- A. weak fluoroscopic shadow of the gall bladder
 - B. sharply increased, not reduced by giving choleretic breakfast
 - C. shadow of the gall bladder
 - D. disconnected" gallbladder
 - E. shadow of suspicion on concretions in the gall bladder at a reduced by 1 / 3 after the administration of choleretic breakfast
298. Patients after cholecystectomy in the immediate postoperative period gradually increase jaundice, these operating cholangiography not indicate the pathology of the bile ducts. The most likely cause of jaundice
- A. serum hepatitis
 - B. common bile duct stone
 - C. hemolytic jaundice
 - D. * operating choledochal injury (ligation)
 - E. all of the above
299. Patients after cholecystectomy in the immediate postoperative period gradually increase jaundice, these operating cholangiography not indicate the pathology of the bile ducts. The most likely cause of jaundice
- A. serum hepatitis
 - B. common bile duct stone
 - C. hemolytic jaundice
 - D. * There is no right answer
 - E. All of the above
300. Patients with suspected calculous cholecystitis for diagnosing stones in the gallbladder indicate:
- A. * abdominal X-ray
 - B. angiography
 - C. Doppler
 - D. celiocentesis
 - E. vulvotsentz
301. Patients with suspected calculous cholecystitis for diagnosing stones in the gallbladder indicate:
- A. * endoscopic retrograde cholangiography
 - B. angiography
 - C. doppler
 - D. laparocentesis
 - E. vulvocentesis

302. Patients with suspected calculous cholecystitis for diagnosing stones in the gallbladder indicate:
- A. * ultrasound abdominal
 - B. angiography
 - C. doppler
 - D. laparocentesis
 - E. vulvocentesis
303. Patients with suspected calculous cholecystitis for diagnosing stones in the gallbladder indicate:
- A. * intravenous cholecystocholangiography
 - B. angiography
 - C. doppler
 - D. laparocentesis
 - E. vulvocentesis
304. The patient admitted to hospital with suspected choledocolithiasis. What method of diagnosis is not used in this case?
- A. ultrasound
 - B. intravenous cholecystocholangiography
 - C. ERPHG
 - D. transhepatic hography
 - E. * hypotonic doudenography
305. The patient admitted to hospital with suspected choledocolithiasis. What method of diagnosis is not used in this case?
- A. ultrasound
 - B. intravenous cholecystocholangiography
 - C. ERPHG
 - D. transhepatic hography
 - E. * all answer are right
306. The patient admitted to hospital with suspected choledocolithiasis. What method of diagnosis is not used in this case?
- A. ultrasound
 - B. intravenous cholecystocholangiography
 - C. ERPHG
 - D. transhepatic hography
 - E. * endoscopy
307. The patient K., 50 years old, six months after cholecystectomy performed at the calculouse chronic cholecystitis, again began to appear in the right hypochondrium pain, occasionally accompanied by yellowing of the sclera. Ultrasound examination of the abdominal cavity obvious pathology of the extrahepatic bile duct could not be detected. Which of the following methods is most informative for diagnosis in this case?
- A. infusion hography,
 - B. oral cholecystography,
 - C. * endoscopic retrograde cholangiopancreatography,
 - D. scanning of the liver,
 - E. computed tomography
308. The patient K., 50 years old, six months after cholecystectomy performed at the calculouse chronic cholecystitis, again began to appear in the right hypochondrium pain, occasionally

accompanied by yellowing of the sclera. Which of the following methods is most informative for diagnosis in this case?

- A. infusion holecystography,
 - B. oral cholecystography,
 - C. * SONOGRAPHY
 - D. scanning of the liver,
 - E. computed tomography
309. The patient was diagnosed during surgery iatrogenic injury extrarenal bile ducts. What operation is indicated?
- A. closure of the injury duct separate atraumatic suture needle
 - B. suturing of the duct on the T-shaped drainage
 - C. closure of the duct on Г-shaped drainage
 - D. imposition biliodigestiv anastomosis
 - E. * any of the above
310. The patient with suspected narrowing of the distal common bile duct for diagnosis you must:
- A. * endoscopic retrograde cholangiography
 - B. echocardiography
 - C. laparocentesis
 - D. certain fraction of bilirubin
 - E. definition level of blood flow in truncus coeliacus
311. The patient with suspected narrowing of the distal common bile duct for diagnosis you must:
- A. * there is no right answer
 - B. echo kardiometriya
 - C. laparocentesis
 - D. certain fraction of bilirubin
 - E. definition level of blood flow in truncus coeliacus
312. A patient 30 years complain for the unpleasant feeling in the area of rectum and periodic bleeding at the end of act of defecation, fall off haemorrhoidal knots at defecation. He is ill a few years. The state is satisfactory. At anoscopy enlarged haemorrhoidal knots are determined at 11 hour. What operation is radical in this case?
- A. * Operation of Milligan-Morgan
 - B. Ligation of haemorrhoidal knots
 - C. Operation of Habriel
 - D. Sclerosing injections
 - E. Conservative treatment
313. A patient 36 years complain for pain in a crotch, fever, high temperature. He is ill a 5 days. A disease began acutely. State of middle weight. At a examination slight swelling of buttock on the right, pain at palpation. At the finger inspection of rectum acutely sickly compression, that swelling in a rectum. For a patient diagnosis?
- A. * a acute ishiorectal paraproctitis
 - B. acute submucous paraproctitis
 - C. acute pelviorectal paraproctitis
 - D. extrasphincteric fistula
 - E. thrombosis
314. A patient 36 years complain for pain in a crotch, fever, high temperature. He is ill a 5 days. A disease began acutely. State of middle weight. At a examination slight swelling of buttock on

the right, pain at palpation. At the finger inspection of rectum acutely sickly compression, that swelling in a rectum. What treatment is indicated to the patient?

- A. * opening of paraproctitis
 - B. operation after Habriel
 - C. conservative
 - D. operation after Ryzhykh- 1
 - E. an operation is after Kenu-Mailce
315. A patient 38 years complain for pain in the area of anus, fever. He is ill a 5 days. A disease began acutely. In anamnesis an operation is concerning a acute paraproctitis 2 years ago. At a examination on the left from anus slight swelling, turning, pain at palpation. In the area of scar of 2cm from anus point opening with festering excretions. What treatment is indicated to the patient?
- A. * operation after Habriel
 - B. opening of paraproctitis
 - C. conservative
 - D. operation after Ryzhykh- 1
 - E. an operation is after Kenu-Mailce
316. A patient 38 years complain for pain in the area of anus, fever. He is ill a 5 days. A disease began acutely. In anamnesis an operation is concerning a acute paraproctitis 2 years ago. At a examination on the left from anus slight swelling, turning, pain at palpation. In the area of scar of 2cm from anus point opening with festering excretions. What diagnosis?
- A. * recrudescant paraproctitis
 - B. ishiorectal paraproctitis
 - C. pelviorectal paraproctitis
 - D. submucous paraproctitis
 - E. thrombosis
317. A patient 60 years complain for pain in an anal area, high temperature of body, diarrhoea with constipations, periodically appearance of blood in incandescence. What sign testify in behalf on a acute paraproctitis in this case ?
- A. * pain, high temperature of body
 - B. enterorrhagia
 - C. diarrhoea
 - D. constipations
 - E. only pain
318. A patient with 10-years anamnesis of unspecific ulcerative colitis has periodic swelling of abdomen, feeling of the incomplete emptying, worsening of the general state. On irrigography is absent haustration with circular narrowing in sigmoid bowel. What complication patient has?
- A. * A regeneration to the cancer
 - B. Toxic dilatation
 - C. Bleeding
 - D. Perforation
 - E. Nothing
319. A patient with 10-years anamnesis of unspecific ulcerative colitis has periodic swelling of abdomen, feeling of the incomplete emptying, worsening of the general state. On irrigography is absent haustration with circular narrowing in sigmoid bowel. What operation is prescribed?
- A. * Colproctectomy
 - B. Resection of sigmoid bowel
 - C. Left-side hemicolectomy
 - D. Sigmoidostomy

- E. Right-side hemicolectomy
320. A patient B., 35 years, complains for a periodic pain in abdomen, frequent (up to 16 - 18 on twenty-four hours) unexecuted stool with mucus and blood. An unspecific ulcerative colitis is diagnosed. The sudden stopping of diarrhoea came on a background of heavy intoxication. The indicated changes of signs of disease means:
- A. efficiency of conservative therapy
 - B. * toxic dilatation
 - C. misdiagnosis
 - D. perforation
 - E. hypovolemia
321. At colonoscopy for a patient 60 years old was removed the polypus of sigmoid bowel in the distance 35 cm from anus. Histologically was found a microinvasive cancer an it apex. On it basis it is not found the cancer's cell. What is tactic of doctor?
- A. * Repeated colonoscopies every 3 months
 - B. Radial therapy
 - C. The resection of sigmoid bowel
 - D. Chemotherapy
 - E. Nothing
322. For a patient 25 years acute horseshoe paraproctitis is diagnosed. What operation is indicated ?
- A. * Excision of abscess is with realization of ligature
 - B. Excision of abscess is with imposition of sutures
 - C. Excision of abscess (as Habriel)
 - D. Excision of abscess is with moving of mucous membrane of distal part of rectum
 - E. Conservative treatment
323. For a patient 25 years three month ago the ulcer of rectum is diagnosed. At a complex examination – Wassermann test is positive. What is diagnosis
- A. * venereal limphogranuloma
 - B. hemorrhoids
 - C. paraproctitis
 - D. fistula
 - E. crack of rectum
324. For a patient 26 years a acute ishiorectal paraproctitis is diagnosed. What operation is indicated ?
- A. * Excision of abscess is with realization of ligature
 - B. Excision of abscess is with imposition of sutures
 - C. Excision of abscess (by Habriel)
 - D. Excision of abscess is with moving of mucous membrane of distal part of rectum
 - E. Conservative treatment
325. For a patient 27 years a acute subcutaneus paraproctitis is diagnosed. What operation is indicated?
- A. * Excision of abscess (as Habriel)
 - B. Excision of abscess is with imposition of sutures
 - C. Excision of abscess is with realization of ligature
 - D. Excision of abscess is with moving of mucous membrane of distal part of rectum
 - E. Conservative treatment

326. For a patient 28 years a chronic transsphincteric paraproctitis is diagnosed. What operation is indicated ?
- A. * Excision of fistula is with the partial suturing of bottom of wound
 - B. Excision of fistula (as Habriel)
 - C. Excision of fistula is with realization of ligature
 - D. Excision of fistula is with moving of mucous membrane of distal part of rectum
 - E. Conservative treatment
327. For a patient 29 years a chronic extrasphincteric paraproctitis is diagnosed. What operation is indicated ?
- A. * Excision of fistula is with realization of ligature
 - B. Excision of fistula is with imposition of deaf sutures
 - C. Excision of fistula (as Habriel)
 - D. Excision of fistula is with moving of mucous membrane of distal part of rectum
 - E. Conservative treatment
328. For a patient a 23 combined hemorrhoids became complicated by bleeding. Pregnancy of 9 weeks. Tactic?
- A. * operation after Milligan-Morgan
 - B. operation after Habriel
 - C. to conduct operative intervention of after birth of child
 - D. after Ryzhykh- 1
 - E. for Kenu-Mailce
329. For a patient an unspecific ulcerative colitis is diagnosed. Prescribed anti-recurrent treatment. What is preparation of choice in treatment of disease?
- A. NSAID
 - B. Lipofundinum
 - C. Smecta
 - D. * Sulfasalasin
 - E. Salbutamololum
330. For a patient intersphincteric fistula of i is 30 years diagnosed external hemorrhoids. He is ill about 5 years. What operation is indicated?
- A. * After Milligan-Morgan and Habriel
 - B. By Milligan-Morgan.
 - C. By Habriel.
 - D. Operation Blinnichev.
 - E. Operation Ryzhykh- 1.
331. For a patient R. 58 years diagnosed fall-out of rectum of III stage. A capacity and quality of life of patient is bad. What is operation in this case?
- A. * Kumel-Zerenin.
 - B. Milligan-Morgan.
 - C. Kenu-Mailce.
 - D. Habriel.
 - E. Operation Blinnichev.
332. For a patient the combined hemorrhoids, complicated by a thrombosis, is diagnosed. A patient is disturbed by pain, discomfort, itch. What is the indication to the operation in this case
- A. * thrombosis of haemorrhoidal nodes
 - B. age
 - C. pain
 - D. itch

- E. discomfort
333. For a patient the unspecific ulcerative colitis of middle weight is diagnosed. It is prescribed prednisolon. What most optimal dose can be used in treatment of disease?
- A. 10-20 mg
 - B. 30-40 mg
 - C. * 60-80 mg
 - D. 35 mg.
 - E. 100 mg.
334. For a patient E., 67p., the perforation of bowel came on a background of unspecific ulcerative colitis. What operative treatment is indicated for the patient?
- A. * Suturing of perforation and ileostomy
 - B. Proximal colostomy
 - C. Total colectomy and ileostomy
 - D. Resection of segment of bowel with perforation
 - E. Conservative treatment
335. For a patient K., 37 years, an unspecific ulcerative colitis is diagnosed. Prescribe conservative treatment:
- A. Diet therapy (exception of milk and dairies)
 - B. Vitamin therapy
 - C. Sulphanilamide
 - D. Desintoxication therapy
 - E. * All listed are true
336. For a patient K., 37p., an unspecific ulcerative colitis is diagnosed. What does not prescribed at unspecific ulcerative colitis for treatment?
- A. Antibiotics
 - B. * Purgatives
 - C. Vitamins
 - D. Desintoxication therapy
 - E. Hormonal preparations
337. For a patient M., 45p., a unspecific ulcerative colitis is diagnosed. It is conducted irrigography. On a sciagram the characteristic sign of this disease is founded. It is a symptom:
- A. index finger"
 - B. roadways"
 - C. water-pipe"
 - D. half of month"
 - E. niches"
338. For a patient M., 45p., it is diagnosed unspecific ulcerative colitis, phase of remission. What is preparation of choice in treatment of disease?
- A. antiagregant
 - B. cytostatics
 - C. vitamins of group In
 - D. * preparations of 5-aminosalicile acid
 - E. hormones
339. For a patient C., 44 years., erosive proctitis is diagnosed. What is preparation of choice in treatment of disease?
- A. Antibiotics
 - B. Hormonal preparations

- C. * Sulphosalaso-drugs
 - D. Enzymes preparations
 - E. Vitamins
340. For a patient C., 45 years, poliposis of colon and rectum is diagnosed. A diagnosis is confirmed by irrigography. What symptom is characteristic for the indicated disease?
- A. water-pipe"
 - B. shot through target"
 - C. a specific symptom is absent
 - D. cockades"
 - E. roadways".
341. For a patient, 39p., an unspecific ulcerative colitis is diagnosed. In the case of development of complications, which complication does not need operative treatment?
- A. * Bleeding
 - B. Toxic megacolon
 - C. Water-electrolyte changes
 - D. Malignancy
 - E. Perforation
342. For the patient of 22 during 2 years it is diagnosed combined haemorrhoid. On this time - pregnancy 8 weeks. Tactic?
- A. * to conduct operative treatment after birth of child
 - B. operation after Habriel
 - C. operation after Milligan-Morgan
 - D. after Ryzhykh- 1
 - E. for Kenu-Mailce
343. For the patient of 24 years on posterior anal is founded fissure of mucous rectum. Pregnancy of 16 weeks. Tactic of surgeon.
- A. * Cut off fissure after birth of child
 - B. operation after Milligan-Morgan
 - C. operation after Habriel
 - D. cut off fissure
 - E. operation after Kenu-Mailce
344. For the patient of 60 year during last 5 years it is diagnosed fall-out of rectum. On this time it is II degree. Quality of life of patient is severe. What operation is indicated?
- A. * Kumel-Zerenin.
 - B. Milligan-Morgan.
 - C. Kenu-Mailce.
 - D. Habriel.
 - E. Operation Blinnichev.
345. On irrigography is found the symptoms of «water-pipe», «shot through target». What is diagnosis?
- A. * Unspecific ulcerative colitis
 - B. Crohn disease
 - C. Dysentery
 - D. Salmonellosis
 - E. Food toxicoinfection
346. Patient of Б., 30 years, a previous diagnosis is: Poliposis of colon. What most reliable method of diagnostics of polypus's of colon is indicated to the patient?:

- A. X-Ray with sulphate of barium
 - B. Irrigoscopy
 - C. * Colonoscopy
 - D. Examination of excrement
 - E. Laparoscopy
347. Patient of K, 45 years, diagnosis: unspecified ulcerative colitis. What treatment is indicated to the patient?
- A. Complete parenterally feed
 - B. Total colectomy with an ileostomy
 - C. Subtotal colectomy with ileostomy
 - D. * All are true
 - E. All are false
348. Patient 27 years old has stomach-ache, liquid stool up to 10 times per days with mucus and blood, weakness, weight lost. On the irrigigrahy is narrowing of transvers colon. What diagnosis?
- A. * Cancer of transvers colon.
 - B. Dysentery.
 - C. Polypus of small intestine.
 - D. Spastic colitis.
 - E. Unspecific ulcerative colitis
349. Patient 40 years complines for pain during time of defecation, spasm of sphincter, bleeding. These symptoms are characteristic for ?
- A. * anal fissure
 - B. proctopolypus
 - C. unspecific ulcerative colitis
 - D. shrine of rectum
 - E. a right answer is not
350. Patient 50 years old has permanent pain in the anus, frequent defecation with blood, lost of appetite, weight lost, weakness. What examination is prescribed?
- A. * A biopsy with histological examination
 - B. Radio-active scan
 - C. Selective angiography
 - D. Doplerography
 - E. Sonography
351. Patient 59 years old has suspicion of the tumor of ascending part of colon. What method of examination is the best?
- A. * A colonoscopy with a biopsy
 - B. Irrigography
 - C. Survey sciagraphy
 - D. Sonography
 - E. Endoscopy
352. Patient 72 years old has acute pain in the left half of abdomeb, nausea, delay of stool and gases. He is ill 6 hours. No mucus and blood in stool, not weight lost . Pulse 84 per 1 min. Peristaltic noises is increased periodically. On the X-Ray of organs of abdominal region is present the Kloyber's cup in the left half of abdomen. What diagnosis ?
- A. * Invagination of sigmoid bowel
 - B. Crohn disease
 - C. Poliposis

- D. Unspecific ulcerative colitis
 - E. Diverticulosis
353. Patient during the act of defecation has pain in anal channel, red blood in the stool. What disease?
- A. * Anal fissure
 - B. Haemorrhoids
 - C. Acute paraproctitis
 - D. Cancer of rectum
 - E. Proctopolypus
354. Patient has a general weakness, presence of dark blood in the stool. At a rectoscopy on 11 cm from anus is found the circular narrowing of rectum. What diagnosis?
- A. * Cancer of rectum
 - B. Proctopolypus
 - C. Acute paraproctitis
 - D. Chronic paraproctitis
 - E. Acute proctitis
355. Patient has diarrhea up to 25-30 times per days with blood, has weight lost, general weakness, periodic stomach-ache. He is ill during 1,5 month. What diagnosis?
- A. * Unspecific ulcerative colitis
 - B. colitis
 - C. Pseudopoliposis
 - D. Diverticulosis
 - E. Spastic colitis
356. Patient has swelling from an anal channel during the act of defecation, without pain, with fresh blood after defecation. Previous diagnosis?
- A. * Haemorrhoids
 - B. Anal fissure
 - C. Acute paraproctitis
 - D. Cancer of rectum
 - E. Proctopolypus
357. Patient M., 42 years, complains for moderate pain in abdomen, frequent stool up to 15 times on twenty-four hours. Temperature - 38C. Abdomen is mildly enlarged, painful in the colon. Rectally: enlarged, mildly sickly haemorrhoidal knots, dark blood. Rectoscopy: mucous membrane of colon with hyperaemia, filling out, covered by erosions. In general blood test is anaemia, ESR - a 54 mm/hour. What is drug used in treatment of disease?
- A. Anti-diarrhoea preparations
 - B. Sulphate of magnesium
 - C. * Sulphosalazo-drugs
 - D. Salbutamol
 - E. Moriamin
358. Patient of B., 38 years, entered with complaints of moderate stomach-ache, diarrhoea up to 17 times on twenty-four hours with blood, pus, mucus. Temperature of body is 38 C. Stomach is inflated, painful in the colon projection. Per rectum: dark blood is founded. It is anaemia, ESR - a 42 mm/hour. What is diagnosis?
- A. Enterocolitis
 - B. Crohn's disease.
 - C. Diverticulosis
 - D. * Unspecific ulcerative colitis

- E. Specific ulcerative colitis
359. Patient of B. in 35, complain for periodic pain in a right inguinal area, increase of T to 38C., general weakness, diarrhoea with the admixtures of blood. At a rectoscopy is a "symptom of roadway". What is the most credible diagnosis for a patient?
- Disease of Hirshprung
 - Dysentery
 - Unspecific ulcerative colitis
 - * Crohn's disease
 - Enterocolitis
360. Patient of M., 66 years, became ill suddenly: pain in the left inguinal area, temperature 38 C. At examination insignificant tension of muscle and pain in the left inguinal area. Specify the diagnosis.
- Stenosis of sigmoid bowel
 - * Diverticulitis of sigmoid bowel
 - Poliposis of colon
 - Volvulus of sigmoid bowel
 - Crohn's disease
361. Patient M., 45 years, passed irrigography. Clinically and on the sciagram a toxic megacolon is founded. For what disease these changes is characteristic?
- Crohn's disease
 - Disease of Hirshprung
 - To the syndrome of Gardner
 - To the syndrome of Paits-Egers
 - * Unspecific ulcerative colitis
362. Patient H. 32 years, complains for periodic pain in a right inguinal area, increase of temperature to 38C., general weakness, diarrhoea with the admixtures of blood. At a rectoscopy an edema, hyperaemia, plural erosions, ulcers, festering and necrotizing raid of mucous membrane of intestine, is founded. What possible diagnosis?
- Enterocolitis
 - * Unspecific ulcerative colitis
 - Poliposis
 - Crohn's disease
 - Diverticulitis.
363. Patient, 70 years, during the last 3 months disturb constipation. During the last 2 weeks was absent of stool during 3-4 days. Patient is used purgative drugs. One week ago was bleeding from rectum – up to 200 ml of the fresh blood. Lost of weight up to 10 kg, an appetite is bad. At examination the general state is middle weight. During palpation of abdomen tumour-like formation is palpated in the left iliac area by size 6x8 cm. At percussion - tympanitis. It is not founded any pathology at digital examination of rectum. What previous diagnosis?
- Diverticulitis of sigmoid bowel
 - Megacolon
 - * Tumour of the left half of colon
 - Volvulus of sigmoid bowel
 - No right answer.
364. The patient 32 years complain for the expressed pain in the area of anus, which arises up at the end of act of defecation, admixtures of blood in incandescence. He is ill for a year. Pains were intensive at first, intensity diminished then. At a examination on the back commissure of

anal ring longitudinal linear wound a 21 cm, pale-grey, with the hypertrophied roller.

Operation, that indicated to the patient?

- A. * Cut off the fissure with dosed sphincterotomy.
- B. Suturing of fissure.
- C. Operation Milligan-Morgan.
- D. Operation Habriel.
- E. Operation Noblja.

365. The patient 32 years complain for the expressed pain in the area of anus, which arises up at the end of act of defecation, admixtures of blood in stool. He is ill for a year. Pains were intensive at first, intensity diminished then. At a examination on the back commissure of anal ring longitudinal linear wound 21 cm, pale-grey, with the hypertrophied roller. Your diagnosis?

- A. * Posterior anal fissure
- B. proctopolypus
- C. unspecific ulcerative colitis
- D. cancer of rectum
- E. hemorrhoids

366. The patient of 28 years complain for the unpleasant feeling in the area of rectum and periodic bleeding at the end of act of defecation. He is ill a few years. The state is satisfactory. Palpation of stomach - without pathology. At anoscopy the haemorrhoidal knot are determined at 11 hour, blood with the edema of mucous membrane. Haemoglobin is 100 /L, red corpuscles 2,7 * 10¹². What is a diagnosis?

- A. * Internal haemorrhoid, bleeding, anaemia.
- B. Gastric ulcer, bleeding, anaemia.
- C. Cancer of rectum, bleeding, anaemia.
- D. Unspecific ulcerative colitis, bleeding, anaemia.
- E. Poliposis, bleeding, anaemia.

367. The patient of 29 years complain for the unpleasant feeling in the area of rectum and periodic bleeding at the end of act of defecation. He is ill a few years. The state is satisfactory. Palpation of stomach - without pathology. It is not founded at the examination of anus and finger inspection of pathological structure. At anoscopy the haemorrhoidal knot are determined at 11 hour, blood with the edema of mucous membrane. Haemoglobin is 100 /L; red corpuscles 2,7 * 10¹². Treatment?

- A. * Operation Milligan-Morgan.
- B. Ryzhykh- 1.
- C. Ryzhykh- 2.
- D. Operation Habriel.
- E. Operation Blinnichev.

368. The patient of 33 complain for the unpleasant feeling in the area of rectum and periodic bleeding at the end of act of defecation, fall off haemorrhoidal knots at defecation. He is ill a few years. The state is satisfactory. At anoscopy are enlarged haemorrhoidal knots and opening of incomplete intersphincteric fistula determined. What operation is radical in this case?

- A. * After Milligan-Morgan and Habriel.
- B. For Milligan-Morgan.
- C. For Habriel.
- D. Operation Blinnichev.
- E. Operation Ryzhykh- 1.

369. The patient of 33 years complain for the expressed pains in the area of anus, that arise up at the end of act of defecation, admixtures of blood in incandescence. He is ill for a year. Pains were intensive at first, intensity diminished then. At a examination on the back commissure of

anal ring longitudinal linear wound a 21 cm, pale-grey, with the hypertrophied roller. On a 2 cm higher line of comb polypus on a narrow leg diameter by 0.5 cm. What operations at posterior anal fissure with polypus?

- A. * Cut off of fissure and removal of polypus
- B. Cut off of fissure.
- C. For Milligan-Morgan.
- D. For Habriel.
- E. Operation Blinnichev.

370. The patient of 43 after the operation of haemorrhoidectomy had cicatrice stricture of anus. What operation is indicated?

- A. * dosed sphincterotomy and suturing of mucous rectum to perianal skin
- B. bougie of rectum from suturing of mucous rectum to perianal skin
- C. dosed sphincterotomy
- D. hemorrhoidectomy
- E. colostomy

371. The patient of B., 47 years, entered to surgical department with complaints for pain in the left inguinal area, weight lost. Objectively: T- 38 C. Stomach troubles, painful at palpation in the left inguinal area. At rectoscopy hyperaemia and deep cracks of mucous membrane, ulcer, stenosis is founded. What is preparation of choice in treatment of disease?

- A. Anticoagulants
- B. * 5-ASK, sulfasalasin, NSAID
- C. NSAID
- D. mercaptopurine
- E. Smecta, Imodium.

372. The patient M., 38 years, entered to surgical department with complaints for periodic pain in a right inguinal area, which arises up after the reception of meal, weight lost. Objectively: T- 38 C. Stomach is subinflated, painful at palpation in the left inguinal area. At rectoscopy is hyperaemia and deep cracks of mucous membrane, ulcer, stenosis. What is the diagnosis of patient?

- A. Dysentery
- B. Disease of Hirshprung.
- C. * Crohn's disease
- D. Unspecific ulcerative colitis
- E. Salmonellas

373. The patient C., in 46 years, entered with complaints of pain in the left inguinal area, diarrhoea up to 20-30 times on twenty-four hours, with the admixtures of blood and mucus. T - 38 °C. Per rectum is a mucous with hyperaemia, swelling, covered by the ulcers of different size, with bleeding. What disease?

- A. Diverticulums
- B. Polyps
- C. Poliposis
- D. Diverticulosis
- E. * Unspecific ulcerative colitis

374. To the patient K., 62 years, roentgenologically and on colonoscopy is diagnosed unspecific ulcerative colitis. What method of treatment of this patient?

- A. * enemas with sulfasalasin
- B. enemas with smecta
- C. enemas with NSAID
- D. enemas with cytostatics

- E. enemas with a celandine
375. A man 50 years of asymptomatic mixed goiter. At the first stage, it should appoint
- A. thyroid hormones to suppress the function of cancer
 - B. propylthiouracil
 - C. subtotal thyroidectomy
 - D. radioiodine
 - E. * only observation
376. In patient K, aged 26, noted a relapse of hyperthyroidism after medical treatment. Your tactics.
- A. Continue medical treatment
 - B. * Surgical treatment
 - C. Outpatient
 - D. Treatment is not required
 - E. Is no right answer
377. On examination, the patient was 32 years reveal the formation of the left lobe of the thyroid gland size 4x6 cm, painless at palpation. What additional diagnostic method to assign?
- A. Radiography of the neck
 - B. * Thyroid gland
 - C. Doppler
 - D. Rheovasography
 - E. EEG
378. On examination, the patient was 32 years reveal the formation of the left lobe of the thyroid gland size 4x6 cm, painless at palpation. What analysis should be performed in order to clarify the diagnosis?
- A. Total blood
 - B. Urinalysis
 - C. Immunogram
 - D. * Thyroid hormones
 - E. Protein fraction
379. Patient D, aged 39, admitted to the hospital with the diagnosis: diffuse toxic goiter. What study be done.
- A. ENDOSCOPY
 - B. Is no right answer
 - C. Rheovasography
 - D. * Investigation of iodine hormones in the blood serum
 - E. Doppler
380. Patient J., 57, was admitted to the surgical clinic with a diagnosis: euthyroid nodular goiter. Choose the correct treatment option.
- A. enucleation
 - B. medication
 - C. subtotal resection of the thyroid gland
 - D. * resection of the thyroid gland with maximal preservation of healthy tissue and routine histological examination
 - E. excision of the node with the routine histological examination
381. Patient K, aged 49, was admitted to the hospital with the diagnosis: diffuse toxic goiter. What study be done.
- A. ENDOSCOPY

- B. Rheovasography
 - C. * Scanning of the thyroid gland
 - D. Doppler
 - E. There is no correct answer
382. Patient K., aged 45, lives in the area of iodine deficiency, was admitted to the clinic with complaints of enlarged thyroid gland. What is the most likely diagnosis in a patient?
- A. * goiter
 - B. acute strumitis
 - C. sporadic goiter
 - D. epidemic goiter
 - E. mass thyrotoxicosis
383. Patient M, 39 years old, was admitted to the hospital with the diagnosis: diffuse toxic goiter. What study be done.
- A. ENDOSCOPY
 - B. * Thyroid gland
 - C. Rheovasography
 - D. Doppler
 - E. Is no right answer
384. Patient M., aged 35, lives in the area of iodine deficiency, was admitted to the clinic with complaints of enlarged thyroid gland. What is the most likely diagnosis in a patient?
- A. acute strumitis
 - B. * there is no right answer
 - C. sporadic goiter
 - D. epidemic goiter
 - E. mass thyrotoxicosis
385. Patient O., aged 39, on the diffuse toxic goiter performed subtotal resection of the thyroid gland. One day the patient became restless, twitching of facial muscles appeared convulsive reduction of hands. Treatment.
- A. * the introduction of calcium chloride intravenously
 - B. introduction Seduxen
 - C. introduction of iodine
 - D. infusion therapy
 - E. introduction of calcium chloride oral
386. Patient O., aged 39, on the diffuse toxic goiter performed subtotal resection of the thyroid gland. One day the patient became restless, twitching of facial muscles appeared convulsive reduction of hands. What mated complication of surgery?
- A. Iodine deficiency
 - B. Lack of thyroid tissue
 - C. * Removal of parathyroid glands
 - D. Increased thyroid hormone
 - E. Increased parathyroid hormone
387. Patient S., 43, in the last 5 months of worry tearfulness, irritability, fatigue, progressive weight loss. On palpation the thyroid gland increased to III class., painless. Pulse 110-120 in minute, regular, blood pressure - 150/80. At SONOGRAPHY: tissue homogeneous, tissue hypertrophy hyper. The most likely diagnosis
- A. Hashimoto struma
 - B. * toxic goiter
 - C. Acute thyroiditis

- D. nodular goiter
 - E. goiter De Quervain
388. Patient S., 43, in the last 5 months of worry tearfulness, irritability, fatigue, progressive weight loss. On palpation the thyroid gland increased to III class., painless. Pulse 110-120 in minute, regular, blood pressure - 150/80. At SONOGRAPHY: tissue homogeneous, tissue hypertrophy hyper. The most likely diagnosis
- A. Hashimoto's thyroiditis
 - B. * there is no right answer
 - C. Acute thyroiditis
 - D. nodular goiter
 - E. goiter De Quervain
389. Patient S., 43, in the last 5 months of worry tearfulness, irritability, fatigue, progressive weight loss. On palpation the thyroid gland increased to III class., painless. Pulse 110-120 in minute, regular, blood pressure - 150/80. What additional diagnostic method to assign?
- A. Radiography of the neck
 - B. * Thyroid gland
 - C. Doppler
 - D. Reovazogrifyu
 - E. EEG
390. Patient S., 43, in the last 5 months of worry tearfulness, irritability, fatigue, progressive weight loss. On palpation the thyroid gland increased to III class., painless. Pulse 110-120 in minute, regular, blood pressure - 150/80. What analysis should be performed in order to clarify the diagnosis?
- A. Total blood
 - B. Urinalysis
 - C. * Thyroid hormones
 - D. Protein fraction
 - E. Immunogram
391. Patients after resection of the thyroid having convulsions, symptoms by Chvostek and Trousseau. What a complication arose in a patient?
- A. * there is no right answer
 - B. laryngeal nerve injury
 - C. residual effects of hyperthyroidism
 - D. thyrotoxic crisis
 - E. hypothyroidism
392. Patients after resection of the thyroid having convulsions, symptoms by Chvostek and Trousseau. What a complication is arose in a patient?
- A. laryngeal nerve injury
 - B. * hypoparathyreosis
 - C. residual effects of hyperthyroidism
 - D. thyrotoxic crisis
 - E. hypothyroidism
393. The patient complaints of excessive sweating, hand tremor, exophthalmos. The most likely diagnosis.
- A. Goiter
 - B. Tireodit
 - C. Thyrotoxicosis
 - D. * Strumil

- E. Is no right answer
394. The patient diagnosed with an aberrant goiter. Refine the definition of aberrant goiter.
- A. metastases of thyroid cancer in the liver
 - B. atypical location of the thyroid gland
 - C. * is a cancer of the thyroid gland
 - D. all true
 - E. all wrong
395. The patient diagnosed with nodular euthyroid goiter left lobe of the thyroid gland. What is the optimal treatment option.
- A. excision of the node with the routine histological examination
 - B. enucleation site
 - C. subtotal thyroidectomy
 - D. * hemistrumectomy or resection of the lobe of the thyroid gland
 - E. conservative treatment thyroidin
396. The patient lives in the area of endemic iodine. What can be used to prevent goitre?
- A. merkasalil
 - B. vaccination
 - C. iodine
 - D. improving the social life of the population
 - E. * iodination salt
397. The patient S., 546 years old, diagnosed with goiter II degree. What is characteristic of the III degree of increase in thyroid gland?
- A. giant goiter
 - B. determined only by palpation
 - C. * visible swallowing
 - D. visible only when swallowing
 - E. determined only on ultrasound
398. The patient S., 61, suffering for 2 years nodular goiter, recently noted a rapid increase in the node. On scanning image identified a "cold node". Specify the most probable cause of this condition
- A. * node malignancy
 - B. cystic degeneration of the node
 - C. autoimmune
 - D. all true
 - E. hemorrhage site
399. The patient S., 61, suffering for 2 years nodular goiter, recently noted a rapid increase in the node. What method of diagnosis is the most informative?
- A. X-ray of the neck
 - B. * scanning with radioactive iodine
 - C. Doppler
 - D. Rheovasography
 - E. EEG
400. The patient V., age 56, diagnosed with goiter of third degree. What is characteristic of the III degree of increase in thyroid gland?
- A. giant goiter
 - B. determined only by palpation
 - C. * visible without swallowing

- D. visible only when swallowing
- E. determined only on ultrasound

401. The patient's 43 years revealed an increase in the left lobe of the thyroid gland. When scanning in this region found a hot site. Diagnosis.

- A. diffuse non-toxic goiter
- B. toxic goiter
- C. multinodular toxic goiter
- D. * nodular toxic goiter
- E. non-toxic nodular goiter

402. The patient's 60 years in the last 3 months has been rapidly increasing dense mass in the left lobe of the thyroid gland. Effects of hyperthyroidism is not. At thyroid scan revealed a cold junction. Preliminary diagnosis

- A. * thyroid cancer
- B. lipoma of the thyroid gland
- C. cyst
- D. metastasis of lung cancer
- E. thyroid cyst

MODULE 2. THORACIC, CARDIOVASCULAR AND ENDOCRINE SURGERY.

Text test questions

1. What is the abscessing pneumonia characterized by?
 - A. *Multiple destructive foci 0,3-0,5 cm in size within 1-2 segments of lungs
 - B. Purulent destruction of pulmonary tissue within 1 segment with formation of cavity, filled by pus
 - C. Purulent, necrosis of a pulmonary tissue within 2-3 segments, detached from adjacent pulmonary parenchyma
 - D. Diffuse purulent, ichorous necrosis more than lobe without the tendency to defined demarcation
 - E. Accumulation of pus in a pleural cavity
2. What is the lung abscess characterized by?
 - A. *Purulent destruction of pulmonary tissue within 1 segment with formation of cavity, filled by pus
 - B. Multiple destructive foci 0,3-0,5 cm in size within 1-2 segments of lungs
 - C. Purulent, necrosis of a pulmonary tissue within 2-3 segments, detached from adjacent pulmonary parenchyma
 - D. Diffuse purulent, ichorous necrosis more than lobe without the tendency to defined demarcation
 - E. Accumulation of pus in a pleural cavity
3. What is the lung gangrenous abscess characterized by?
 - A. *Purulent, necrosis of a pulmonary tissue within 2-3 segments, detached from adjacent pulmonary parenchyma
 - B. Multiple destructive foci 0,3-0,5 cm in size within 1-2 segments of lungs
 - C. Purulent destruction of pulmonary tissue within 1 segment with formation of cavity, filled by pus
 - D. Diffuse purulent, ichorous necrosis more than lobe without the tendency to defined demarcation
 - E. Accumulation of pus in a pleural cavity
4. What is the lung gangrene characterized by?
 - A. *Diffuse purulent, ichorous necrosis more than lobe without the tendency to defined demarcation
 - B. Multiple destructive foci 0,3-0,5 cm in size within 1-2 segments of lungs
 - C. Purulent destruction of pulmonary tissue within 1 segment with formation of cavity, filled by pus
 - D. Purulent, necrosis of a pulmonary tissue within 2-3 segments, detached from adjacent pulmonary parenchyma
 - E. Accumulation of pus in a pleural cavity
5. Multiple destructive foci 0,3-0,5 cm in size within 1-2 segments of lungs are called:
 - A. *Abscessing pneumonia
 - B. Lung abscess
 - C. Lung gangrenous abscess
 - D. Lung gangrene
 - E. Bronchoectatic disease
6. Purulent destruction of pulmonary tissue within 1 segment with formation of cavity, filled by pus is called:
 - A. *Lung abscess
 - B. Abscessing pneumonia
 - C. Lung gangrenous abscess
 - D. Lung gangrene
 - E. Bronchoectatic disease

7. Purulent, necrosis of a pulmonary tissue within 2-3 segments, detached from adjacent pulmonary parenchyma is called:
 - A. *Lung gangrenous abscess
 - B. Lung abscess
 - C. Abscessing pneumonia
 - D. Lung gangrene
 - E. Bronchoectatic disease
8. Diffuse purulent, ichorous necrosis beyond the lobe without the tendency to defined demarcation is called:
 - A. *Lung gangrene
 - B. Lung gangrenous abscess
 - C. Lung abscess
 - D. Abscessing pneumonia
 - E. Bronchoectatic disease
9. What type of the lung gangrene is considered to be limited?
 - A. *The lesion within 1 lobe
 - B. The lesion within 1 segment
 - C. The total lesion of 1 lung
 - D. The lesion of 2 lungs
 - E. The lesion of lungs and pleura
10. What is the I stage of lung abscess?
 - A. *Necrotic pneumonia
 - B. Asymptomatic
 - C. Destruction and rejection
 - D. Cleaning and cicatrization
 - E. Gangrenous
11. What is the II stage of lung abscess?
 - A. *Destruction and rejection
 - B. Asymptomatic
 - C. Necrotic pneumonia
 - D. Cleaning and cicatrization
 - E. Gangrenous
12. What is the III stage of lung abscess?
 - A. *Cleaning and cicatrization
 - B. Asymptomatic
 - C. Necrotic pneumonia
 - D. Destruction and rejection
 - E. Gangrenous
13. What stage of lung abscess correlates with the necrotic pneumonia?
 - A. *I
 - B. II
 - C. III
 - D. IV
 - E. V
14. What stage of lung abscess correlates with the destruction and rejection?
 - A. *II
 - B. I
 - C. III
 - D. V
 - E. IV
15. What stage of lung abscess correlates with the cleaning and cicatrization?
 - A. *III
 - B. II
 - C. I

- D. IV
 - E. V
16. What is the predominant factor which causes the lung abscess?
 - A. *Disturbances of bronchial permeability with the development of atelectasis
 - B. Increased cholesterol, dyslipoproteinemia
 - C. Pulmonary hypertension
 - D. Rheumatism, endocarditis
 - E. Myocardial infarction
 17. What is the predominant factor which causes the lung abscess?
 - A. *Infection in a pulmonary tissue
 - B. Increased cholesterol, dyslipoproteinemia
 - C. Pulmonary hypertension
 - D. Rheumatism, endocarditis
 - E. Myocardial infarction
 18. What is the predominant factor which causes the lung abscess?
 - A. *Regional disturbances of pulmonary blood supply with a further necrosis of parenchyma
 - B. Increased cholesterol, dyslipoproteinemia
 - C. Pulmonary hypertension
 - D. Rheumatism, endocarditis
 - E. Myocardial infarction
 19. What acute complication is characteristic for lung abscess?
 - A. *Pulmonary bleeding
 - B. Emphysema
 - C. Rib fracture
 - D. Malignancy
 - E. Esophageal bleeding
 20. What acute complication is characteristic for lung abscess?
 - A. *Pyopneumothorax
 - B. Rib fracture
 - C. Emphysema
 - D. Malignancy
 - E. Esophageal bleeding
 21. What complication is characteristic for lung abscess?
 - A. *Pleural empyema
 - B. Esophageal bleeding
 - C. Rib fracture
 - D. Emphysema
 - E. Malignancy
 22. What complication is characteristic for lung abscess?
 - A. *Sepsis
 - B. Esophageal bleeding
 - C. Rib fracture
 - D. Emphysema
 - E. Malignancy
 23. What complication is characteristic for lung abscess?
 - A. *Bronchogenic dissemination
 - B. Esophageal bleeding
 - C. Rib fracture
 - D. Emphysema
 - E. Malignancy
 24. For the clinical manifestation of lung abscess is typical:
 - A. *Chest pain
 - B. Abdominal pain

- C. Paralysis of intercostal nerve
 - D. Edema of legs
 - E. Dilated cervical veins
25. For the clinical manifestation of lung abscess is typical:
- A. *Dyspnea
 - B. Abdominal pain
 - C. Paralysis of intercostal nerve
 - D. Edema of legs
 - E. Dilated cervical veins
26. For the clinical manifestation of lung abscess is typical:
- A. *Fever to 39-40°C
 - B. Abdominal pain
 - C. Paralysis of intercostal nerve
 - D. Edema of legs
 - E. Dilated cervical veins
27. For the clinical manifestation of lung abscess is typical:
- A. *Troubling cough
 - B. Abdominal pain
 - C. Paralysis of intercostal nerve
 - D. Edema of legs
 - E. Dilated cervical veins
28. For the clinical manifestation of lung abscess is typical:
- A. *Intoxication
 - B. Abdominal pain
 - C. Paralysis of intercostal nerve
 - D. Edema of legs
 - E. Dilated cervical veins
29. For the clinical manifestation of lung abscess is typical:
- A. *Troubling cough with foul-smelling sputum
 - B. Abdominal pain
 - C. Paralysis of intercostal nerve
 - D. Edema of legs
 - E. Dilated cervical veins
30. The fever to 39-40°C is typical for:
- A. *Lung abscess
 - B. Bronchitis
 - C. Lung emphysema
 - D. Pulmonary hypertension
 - E. Lung cyst
31. The chest pain is typical for:
- A. *Lung abscess
 - B. Bronchitis
 - C. Lung emphysema
 - D. Pulmonary hypertension
 - E. Lung cyst
32. The intoxication is typical for:
- A. *Lung abscess
 - B. Bronchitis
 - C. Lung emphysema
 - D. Pulmonary hypertension
 - E. Lung cyst
33. The troubling cough with foul-smelling sputum is typical for:
- A. *Lung abscess
 - B. Bronchitis

- C. Lung emphysema
 - D. Pulmonary hypertension
 - E. Lung cyst
34. What is revealed in acute lung abscess by percussion?
- A. *Blunted sound
 - B. Bandbox sound
 - C. Tympanic sound
 - D. Clear sound
 - E. Pulmonary sound
35. The blunted sound by percussion is typical for:
- A. *Lung abscess
 - B. Bronchitis
 - C. Lung emphysema
 - D. Pneumothorax
 - E. Lung cyst
36. The blunted sound by percussion is typical for:
- A. *Pneumonia
 - B. Bronchitis
 - C. Lung emphysema
 - D. Pneumothorax
 - E. Lung cyst
37. The blunted sound by percussion is typical for:
- A. *Lung gangrene
 - B. Bronchitis
 - C. Lung emphysema
 - D. Pneumothorax
 - E. Lung cyst
38. What is revealed in the I stage of acute lung abscess by auscultation?
- A. *Bronchial breathing with moist rales
 - B. Vesicular breathing
 - C. Amphoric breathing with moist rales
 - D. Harsh breathing with dry rales
 - E. The breathing isn't auscultated
39. What is revealed in the II stage (after draining) of acute lung abscess by auscultation?
- A. *Amphoric breathing with moist rales
 - B. Vesicular breathing
 - C. Bronchial breathing with moist rales
 - D. Harsh breathing with dry rales
 - E. The breathing isn't auscultated
40. What is revealed in the I stage of acute lung abscess by X-ray?
- A. *Rounded shadow with irregular contour
 - B. Rounded cavity with air-fluid level
 - C. Expressed fibrosis
 - D. Intensive shadow of a considerable area of lung with cavities and fluid levels
 - E. One or several cavities with a thick, dense pyogenic sheath
41. What is revealed in the II stage (after draining) of acute lung abscess by X-ray?
- A. *Rounded cavity with air-fluid level
 - B. Rounded shadow with irregular contour
 - C. Expressed fibrosis
 - D. Intensive shadow of a considerable area of lung with cavities and fluid levels
 - E. One or several cavities with a thick, dense pyogenic sheath
42. What is revealed in the III stage of acute lung abscess by X-ray?
- A. *Expressed fibrosis
 - B. Rounded shadow with irregular contour

- C. Rounded cavity with air-fluid level
 - D. Intensive shadow of a considerable area of lung with cavities and fluid levels
 - E. One or several cavities with a thick, dense pyogenic sheath
43. What is revealed in lung gangrene by X-ray?
- A. *Intensive shadow of a considerable area of lung with cavities and fluid levels
 - B. Rounded shadow with irregular contour
 - C. Rounded cavity with air-fluid level
 - D. Expressed fibrosis
 - E. One or several cavities with a thick, dense pyogenic sheath
44. What is revealed in chronic lung abscess by X-ray?
- A. *One or several cavities with a thick, dense pyogenic sheath
 - B. Rounded shadow with irregular contour
 - C. Rounded cavity with air-fluid level
 - D. Expressed fibrosis
 - E. Intensive shadow of a considerable area of lung with cavities and fluid levels
45. The rounded shadow with irregular contour on X-ray is typical for:
- A. *I stage of acute lung abscess
 - B. II stage of acute lung abscess
 - C. III stage of acute lung abscess
 - D. Lung emphysema
 - E. Lung cyst
46. The rounded cavity with air-fluid level on X-ray is typical for:
- A. *II stage of acute lung abscess
 - B. I stage of acute lung abscess
 - C. III stage of acute lung abscess
 - D. Lung emphysema
 - E. Lung cyst
47. The expressed fibrosis on X-ray is typical for:
- A. *III stage of acute lung abscess
 - B. II stage of acute lung abscess
 - C. I stage of acute lung abscess
 - D. Lung emphysema
 - E. Lung cyst
48. The intensive shadow of a considerable area of lung with cavities with sequesters and fluid levels on X-ray is typical for:
- A. *Lung gangrene
 - B. III stage of acute lung abscess
 - C. II stage of acute lung abscess
 - D. Lung emphysema
 - E. Lung cyst
49. One or several cavities with a thick, dense pyogenic sheath on X-ray is typical for:
- A. *Chronic lung abscess
 - B. Lung gangrene
 - C. Acute lung abscess
 - D. Lung emphysema
 - E. Lung cyst
50. When the lung abscess is considered to be chronic?
- A. *In 6-8 weeks after the onset
 - B. In 10 days after the onset
 - C. In 3-4 weeks after the onset
 - D. In 6-8 months after the onset
 - E. In 1 year after the onset
51. What kind of X-ray shadow is typical for acute lung abscess before draining?
- A. *Rounded shadow with considerable perifocal infiltration

- B. Homogeneous spherical shadow with regular edge on the background of intact pulmonary tissue
 - C. Heterogeneous shadow with calcifications, excentric destruction and regular edge
 - D. Homogeneous spherical shadow with irregular edge and phenomena of lymphangitis (corona maligna)
 - E. Heterogeneous shadow with destruction, displaced in the upper lobes, with fibrosis, petrifications in adjacent tissue, peribronchial lymphadenitis
52. What kind of X-ray shadow is typical for lung cyst?
- A. *Homogeneous spherical shadow with regular edge on the background of intact pulmonary tissue
 - B. Rounded shadow with considerable perifocal infiltration
 - C. Heterogeneous shadow with calcifications, excentric destruction and regular edge
 - D. Homogeneous spherical shadow with irregular edge and phenomena of lymphangitis (corona maligna)
 - E. Heterogeneous shadow with destruction, displaced in the upper lobes, with fibrosis, petrifications in adjacent tissue, peribronchial lymphadenitis
53. What kind of X-ray shadow is typical for tuberculoma?
- A. *Heterogeneous shadow with calcifications and regular edge
 - B. Homogeneous spherical shadow with regular edge on the background of intact pulmonary tissue
 - C. Rounded shadow with considerable perifocal infiltration
 - D. Homogeneous spherical shadow with irregular edge and phenomena of lymphangitis (corona maligna)
 - E. Heterogeneous shadow with destruction, displaced in the upper lobes, with fibrosis, petrifications in adjacent tissue, peribronchial lymphadenitis
54. What kind of X-ray shadow is typical for peripheral lung cancer?
- A. *Homogeneous spherical shadow with irregular edge and phenomena of lymphangitis (corona maligna)
 - B. Homogeneous spherical shadow with regular edge on the background of intact pulmonary tissue
 - C. Rounded shadow with considerable perifocal infiltration
 - D. Heterogeneous shadow with calcifications and regular edge
 - E. Heterogeneous shadow with destruction, displaced in the upper lobes, with fibrosis, petrifications in adjacent tissue, peribronchial lymphadenitis
55. What kind of X-ray shadow is typical for tubercular cavern?
- A. *Heterogeneous shadow with destruction, displaced in the upper lobes, with fibrosis, petrifications in adjacent tissue, peribronchial lymphadenitis
 - B. Homogeneous spherical shadow with regular edge on the background of intact pulmonary tissue
 - C. Rounded shadow with considerable perifocal infiltration
 - D. Heterogeneous shadow with calcifications and regular edge
 - E. Homogeneous spherical shadow with irregular edge and phenomena of lymphangitis (corona maligna)
56. Homogeneous spherical shadow with regular edge on the background of intact pulmonary tissue on X-ray is typical for:
- A. *Lung cyst
 - B. Tuberculoma
 - C. Peripheral lung cancer
 - D. Tubercular cavern
 - E. Lung emphysema
57. Heterogeneous shadow with calcifications and regular edge on X-ray is typical for:
- A. *Tuberculoma
 - B. Lung cyst
 - C. Peripheral lung cancer

- D. Tubercular cavern
 - E. Lung emphysema
58. Homogeneous spherical shadow with irregular edge and phenomena of lymphangitis (corona maligna) on X-ray is typical for:
- A. *Peripheral lung cancer
 - B. Tuberculoma
 - C. Lung cyst
 - D. Tubercular cavern
 - E. Lung emphysema
59. Heterogeneous shadow with destruction, displaced in the upper lobes, with fibrosis, petrifications in adjacent tissue, peribronchial lymphadenitis on X-ray is typical for:
- A. *Tubercular cavern
 - B. Peripheral lung cancer
 - C. Tuberculoma
 - D. Lung cyst
 - E. Lung emphysema
60. The clinical dynamics of lung abscess which is characterized by prompt positive clinical, roentgenological and laboratory dynamics and recovery after the adequate treatment regards to the:
- A. *Favorable course
 - B. Non-progressive course
 - C. Progressing course
 - D. Incapsulated process
 - E. Complicated course
61. The clinical dynamics of lung abscess which is characterized by transforming of the process into the chronic form due to poor drainage of the suppurative focus and permanent purulent intoxication regards to the:
- A. *Non-progressive course
 - B. Favorable course
 - C. Progressing course
 - D. Incapsulated process
 - E. Complicated course
62. The clinical dynamics of lung abscess which is characterized by expansion of the zone of necrosis and destruction with transforming in gangrene regards to the:
- A. *Progressing course
 - B. Non-progressive course
 - C. Favorable course
 - D. Incapsulated process
 - E. Complicated course
63. The clinical dynamics of lung abscess which is characterized by the partial or complete obstruction of the draining bronchus combined with satisfactory resistance of the organism regards to the:
- A. *Incapsulated process
 - B. Progressing course
 - C. Non-progressive course
 - D. Favorable course
 - E. Complicated course
64. The clinical dynamics of lung abscess which is characterized by different kinds of complications regards to the:
- A. *Complicated course
 - B. Incapsulated process
 - C. Progressing course
 - D. Non-progressive course
 - E. Favorable course

65. What disease doesn't result in pulmonary bleeding?
- A. *Pleurisy
 - B. Lung gangrene and abscess
 - C. Lung cancer
 - D. Tuberculosis
 - E. Bronchiectatic disease
66. What pulmonary hemorrhage is classified as I degree?
- A. *Less than 300 ml
 - B. 300-500 ml
 - C. 500-700 ml
 - D. 700-1000 ml
 - E. More than 1500 ml
67. What pulmonary hemorrhage is classified as II degree?
- A. *500-700 ml
 - B. 50-100 ml
 - C. 100-300 ml
 - D. 700-1000 ml
 - E. More than 1500 ml
68. What pulmonary hemorrhage is classified as III degree?
- A. *More than 700 ml
 - B. 50-100 ml
 - C. 100-300 ml
 - D. 300-500 ml
 - E. 500-700 ml
69. The pulmonary hemorrhage less than 300 ml is classified as:
- A. *I degree
 - B. 0 degree
 - C. II degree
 - D. III degree
 - E. IV degree
70. The pulmonary hemorrhage within 500-700 ml is classified as:
- A. *II degree
 - B. I degree
 - C. 0 degree
 - D. III degree
 - E. IV degree
71. The pulmonary hemorrhage more than 700 ml is classified as:
- A. *III degree
 - B. II degree
 - C. I degree
 - D. 0 degree
 - E. IV degree
72. The coughing out of the bloody sputum without hemodynamic disturbances are characteristic for such degree of pulmonary bleeding:
- A. *I degree
 - B. III degree
 - C. II degree
 - D. 0 degree
 - E. IV degree
73. The decrease of arterial pressure on 20-30 mm Hg is characteristic for such degree of pulmonary bleeding:
- A. *II degree
 - B. I degree
 - C. III degree

- D. 0 degree
 - E. IV degree
74. The amount of hemoglobin within 60-80 g/l is characteristic for such degree of pulmonary bleeding:
- A. *II degree
 - B. I degree
 - C. III degree
 - D. 0 degree
 - E. IV degree
75. The tachycardia to 100 beats/min is characteristic for such degree of pulmonary bleeding:
- A. *II degree
 - B. I degree
 - C. III degree
 - D. 0 degree
 - E. IV degree
76. The decrease of arterial pressure to 40-60 mm Hg is characteristic for such degree of pulmonary bleeding:
- A. *III degree
 - B. II degree
 - C. I degree
 - D. 0 degree
 - E. IV degree
77. The rapid (more than 100-120 beats/min), small, thread pulse is characteristic for such degree of pulmonary bleeding:
- A. *III degree
 - B. II degree
 - C. I degree
 - D. 0 degree
 - E. IV degree
78. The amount of hemoglobin less than 50-60 g/l is characteristic for such degree of pulmonary bleeding:
- A. *III degree
 - B. II degree
 - C. I degree
 - D. 0 degree
 - E. IV degree
79. What is the main method of lung abscess sanitation?
- A. *Microtracheostomy
 - B. Transpleural
 - C. Transesophageal
 - D. Endovascular
 - E. Thoracotomy
80. What is the main treatment of noncomplicated acute lung abscess?
- A. *Conservative treatment
 - B. Segmentectomy
 - C. Lobectomy
 - D. Pneumonectomy
 - E. Pleural puncture
81. What medicine drug belongs to broad spectrum antibiotics?
- A. *Ceftriaxon, Ciprinol
 - B. Euphyllin, No-spa
 - C. Vasaprostan, Alprostan
 - D. Nicotine acid, Heparin
 - E. Detrlex, Venoplant

82. What medicine drug belongs to broad spectrum antibiotics?
- A. *Tebris, Ciprinol
 - B. Dimedrol, Suprastin
 - C. Vasaprostan, Alprostan
 - D. Nicotine acid, Heparin
 - E. Detrlex, Venoplant
83. What medicine drug belongs to broad spectrum antibiotics?
- A. *Zanocin
 - B. Naclofen
 - C. Vasaprostan
 - D. Nicotine acid
 - E. Omeprasol
84. What medicine used for the treatment of pulmonary bleeding?
- A. *Aminocapronic acid
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
85. What medicine used for the treatment of pulmonary bleeding?
- A. *Calcium chloridi
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
86. What medicine used for the treatment of pulmonary bleeding?
- A. *Dicinon
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
87. What medicine used for the treatment of pulmonary bleeding?
- A. *Vitamin K
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
88. What medicine used for the treatment of pulmonary bleeding?
- A. *Benzohexonium
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
89. What is the indication for operative treatment of acute abscess of lungs?
- A. *Pulmonary bleeding of II- III degree
 - B. Decompensation of the vital organs
 - C. Bilateral purulent destruction of lungs
 - D. Incurable malignant tumours
 - E. Pulmonary hypertension
90. What is the indication for operative treatment of acute abscess of lungs?
- A. *Progression of the process despite appropriate therapy
 - B. Decompensation of the vital organs
 - C. Bilateral purulent destruction of lungs
 - D. Incurable malignant tumours
 - E. Pulmonary hypertension

91. What is the indication for operative treatment of acute abscess of lungs?
- A. *Tense pyopneumothorax, which is failed to liquify by the draining of pleural space
 - B. Decompensation of the vital organs
 - C. Bilateral purulent destruction of lungs
 - D. Incurable malignant tumours
 - E. Pulmonary hypertension
92. What is the indication for operative treatment of acute abscess of lungs?
- A. *Impossibility to rule out the suspicion on a malignant tumour
 - B. Decompensation of the vital organs
 - C. Bilateral purulent destruction of lungs
 - D. Incurable malignant tumours
 - E. Pulmonary hypertension
93. What operation is performed in complicated acute lung abscess?
- A. *Pneumonectomy, bilobectomy, lobectomy
 - B. Draining of a pleural space
 - C. Transthoracic drainage of the abscess
 - D. Bronchial plastics
 - E. Transplantation of lungs
94. What is the main treatment of chronic lung abscess?
- A. *Pneumonectomy, bilobectomy, lobectomy
 - B. Draining of a pleural space
 - C. Transthoracic drainage of the abscess
 - D. Transplantation of lungs
 - E. Conservative treatment
95. The pneumonectomy is indicated for:
- A. *Chronic lung abscess
 - B. Pneumonia
 - C. Pulmonary hypertension
 - D. Lung emphysema
 - E. Pleural empyema
96. The pneumonectomy is indicated for:
- A. *Complicated lung abscess
 - B. Pneumonia
 - C. Pulmonary hypertension
 - D. Lung emphysema
 - E. Pleural empyema
97. The pneumonectomy is indicated for:
- A. *Lung gangrene
 - B. Pneumonia
 - C. Pulmonary hypertension
 - D. Lung emphysema
 - E. Pleural empyema
98. The pneumonectomy is indicated for:
- A. *Lung cancer
 - B. Pneumonia
 - C. Pulmonary hypertension
 - D. Lung emphysema
 - E. Pleural empyema
99. The pneumonectomy is indicated for:
- A. *Tuberculosis cavern
 - B. Pneumonia
 - C. Pulmonary hypertension
 - D. Lung emphysema
 - E. Pleural empyema

100. What is the cause of pleural empyema?
 - A. *Destructive processes of lungs
 - B. Obstructive bronchitis
 - C. Pulmonary embolism
 - D. Bronchial asthma
 - E. Pulmonary emphysema
101. What is the cause of pleural empyema?
 - A. *Abscesses of abdominal cavity
 - B. Obstructive bronchitis
 - C. Pulmonary embolism
 - D. Bronchial asthma
 - E. Pulmonary emphysema
102. What is the cause of pleural empyema?
 - A. *Open and closed damages of chest
 - B. Obstructive bronchitis
 - C. Pulmonary embolism
 - D. Bronchial asthma
 - E. Pulmonary emphysema
103. What is the cause of pleural empyema?
 - A. *Operative approaches on thoracic organs
 - B. Obstructive bronchitis
 - C. Pulmonary embolism
 - D. Bronchial asthma
 - E. Pulmonary emphysema
104. What sign is not typical for pleural empyema?
 - A. *Hemoptysis
 - B. Pain
 - C. Dyspnea
 - D. Cough
 - E. Intoxication
105. For the clinical manifestation of pleural empyema is typical:
 - A. *Chest pain
 - B. Vomiting
 - C. Regurgitation
 - D. Dysphagia
 - E. Dilated cervical veins
106. For the clinical manifestation of pleural empyema is typical:
 - A. *Dyspnea
 - B. Vomiting
 - C. Regurgitation
 - D. Dysphagia
 - E. Dilated cervical veins
107. For the clinical manifestation of pleural empyema is typical:
 - A. *Cough with sputum
 - B. Vomiting
 - C. Regurgitation
 - D. Dysphagia
 - E. Dilated cervical veins
108. For the clinical manifestation of pleural empyema is typical:
 - A. *Intoxication
 - B. Vomiting
 - C. Regurgitation
 - D. Dysphagia
 - E. Dilated cervical veins

109. What is revealed in pleural empyema by percussion?
- A. *Blunted sound
 - B. Clear sound
 - C. Bandbox sound
 - D. Metallic ringing
 - E. Tympanic sound
110. The blunted sound by percussion is typical for:
- A. *Pleural empyema
 - B. Bronchitis
 - C. Lung emphysema
 - D. Pneumothorax
 - E. Lung cyst
111. The blunted sound by percussion is typical for:
- A. *Pleurisy
 - B. Bronchitis
 - C. Lung emphysema
 - D. Pneumothorax
 - E. Lung cyst
112. What is revealed in pleural empyema by auscultation?
- A. *The breathing isn't auscultated
 - B. Vesicular breathing
 - C. Amphoric breathing with moist rales
 - D. Bronchial breathing with moist rales
 - E. Harsh breathing with dry rales
113. The absence of breathing sounds by auscultation is typical for:
- A. *Pleurisy
 - B. Bronchitis
 - C. Lung emphysema
 - D. Pulmonary hypertension
 - E. Pneumonia
114. The absence of breathing sounds by auscultation is typical for:
- A. *Pleural empyema
 - B. Bronchitis
 - C. Lung emphysema
 - D. Pulmonary hypertension
 - E. Pneumonia
115. What is revealed in wide-spread pleural empyema by X-ray?
- A. *Intensive homogeneous shadow in a basal parts with oblique upper contour
 - B. Rounded shadow with irregular contour
 - C. Rounded cavity with air-fluid level
 - D. Intensive homogeneous shadow in a basal parts with horizontal upper contour
 - E. Lung atelectasis
116. What is the most informative in differential diagnostic of pleural empyema with pleuropneumonia?
- A. *Pleural puncture
 - B. X-ray examination
 - C. Auscultation
 - D. Clinical manifestation
 - E. Sputum analysis
117. What is the most informative in the diagnostic of pleural empyema?
- A. *Pleural puncture
 - B. General blood analysis
 - C. Auscultation
 - D. Clinical manifestation

- E. Sputum analysis
118. The swelled soft tissues of supraclavicular region are typical for the:
- A. *Apical empyema
 - B. Paracostal empyema
 - C. Paramediastinal empyema
 - D. Basal empyema
 - E. Postoperative empyema
119. The restricted thoracic excursion with severe chest pain are typical for the:
- A. *Paracostal empyema
 - B. Apical empyema
 - C. Paramediastinal empyema
 - D. Basal empyema
 - E. Postoperative empyema
120. The heart pain is typical for the:
- A. *Paramediastinal empyema
 - B. Paracostal empyema
 - C. Apical empyema
 - D. Basal empyema
 - E. Postoperative empyema
121. The pain in subcostal area, which increases at respiration is typical for the:
- A. *Paramediastinal empyema
 - B. Paracostal empyema
 - C. Apical empyema
 - D. Basal empyema
 - E. Postoperative empyema
122. What is the typical method of treatment of focal empyema?
- A. *Pleural puncture
 - B. Drainage of pleural space
 - C. Thoracotomy
 - D. Pneumonectomy, bilobectomy, lobectomy
 - E. Conservative treatment
123. What is the typical method of treatment of spread empyema?
- A. *Drainage of pleural space
 - B. Pleural puncture
 - C. Thoracotomy
 - D. Pneumonectomy, bilobectomy, lobectomy
 - E. Conservative treatment
124. Where is the drainage of pleural space in spread empyema performed?
- A. *VII intercostal space, scapular line
 - B. II intercostal space, midclavicular line
 - C. II intercostal space, scapular line
 - D. IV intercostal space, anterior axillary line
 - E. VII intercostal space, midclavicular line
125. What is the typical method of treatment of chronic empyema?
- A. *Pleurectomy, decortication of lung
 - B. Drainage of pleural space
 - C. Thoracotomy
 - D. Pneumonectomy, bilobectomy, lobectomy
 - E. Conservative treatment
126. The pleurectomy is indicated for:
- A. *Chronic empyema
 - B. Complicated lung abscess
 - C. Pneumonia
 - D. Pulmonary hypertension

- E. Lung emphysema
127. The decortication of lung is indicated for:
- A. *Chronic empyema
 - B. Complicated lung abscess
 - C. Pneumonia
 - D. Pulmonary hypertension
 - E. Lung emphysema
128. What is the cause of pyopneumothorax?
- A. *Lung abscess
 - B. Obstructive bronchitis
 - C. Pulmonary embolism
 - D. Bronchial asthma
 - E. Pulmonary emphysema
129. What is the cause of pyopneumothorax?
- A. *Lung gangrene
 - B. Obstructive bronchitis
 - C. Pulmonary embolism
 - D. Bronchial asthma
 - E. Pulmonary emphysema
130. What is the cause of pyopneumothorax?
- A. *Suppurative cyst of lung
 - B. Obstructive bronchitis
 - C. Pulmonary embolism
 - D. Bronchial asthma
 - E. Pulmonary emphysema
131. What is the cause of pyopneumothorax?
- A. *Abscessing pneumonia
 - B. Obstructive bronchitis
 - C. Pulmonary embolism
 - D. Bronchial asthma
 - E. Pulmonary emphysema
132. What is the cause of pyopneumothorax?
- A. *Subphrenic abscess
 - B. Obstructive bronchitis
 - C. Pulmonary embolism
 - D. Bronchial asthma
 - E. Pulmonary emphysema
133. What is the cause of pyopneumothorax?
- A. *Chest trauma
 - B. Obstructive bronchitis
 - C. Pulmonary embolism
 - D. Bronchial asthma
 - E. Pulmonary emphysema
134. What is the cause of pyopneumothorax?
- A. *Bronchiectatic disease
 - B. Obstructive bronchitis
 - C. Pulmonary embolism
 - D. Bronchial asthma
 - E. Pulmonary emphysema
135. For the clinical manifestation of pyopneumothorax is typical:
- A. *Chest pain
 - B. Vomiting
 - C. Regurgitation
 - D. Dysphagia

- E. Dilated cervical veins
136. For the clinical manifestation of pyopneumothorax is typical:
- A. *Dyspnea
 - B. Vomiting
 - C. Regurgitation
 - D. Dysphagia
 - E. Dilated cervical veins
137. For the clinical manifestation of pyopneumothorax is typical:
- A. *Cough with sputum
 - B. Vomiting
 - C. Regurgitation
 - D. Dysphagia
 - E. Dilated cervical veins
138. For the clinical manifestation of pyopneumothorax is typical:
- A. *Intoxication
 - B. Vomiting
 - C. Regurgitation
 - D. Dysphagia
 - E. Dilated cervical veins
139. For the clinical manifestation of pyopneumothorax is typical:
- A. *Hectic fever
 - B. Vomiting
 - C. Regurgitation
 - D. Dysphagia
 - E. Dilated cervical veins
140. What is revealed in pyopneumothorax by percussion?
- A. *Blunt sound over the exudate and bandbox sound over the region of collapsed lung
 - B. Pulmonary sound
 - C. Bandbox sound over the whole lung
 - D. Blunted sound over the whole lung
 - E. Metallic ringing
141. What is revealed in pyopneumothorax by auscultation?
- A. *The breathing isn't auscultated
 - B. Vesicular breathing
 - C. Amphoric breathing with moist rales
 - D. Bronchial breathing with moist rales
 - E. Harsh breathing with dry rales
142. What is revealed in pyopneumothorax by X-ray?
- A. *Intensive homogeneous shadow in a basal parts with horizontal upper contour
 - B. Rounded shadow with irregular contour
 - C. Rounded cavity with air-fluid level
 - D. Intensive homogeneous shadow in a basal parts with oblique upper contour
 - E. Lung atelectasis
143. What is the typical method of treatment of restricted pyopneumothorax?
- A. *Pleural puncture
 - B. Drainage of pleural space
 - C. Thoracotomy
 - D. Pneumonectomy, bilobectomy, lobectomy
 - E. Conservative treatment
144. What is the typical method of treatment of pyopneumothorax?
- A. *Drainage of pleural space
 - B. Pleural puncture
 - C. Thoracotomy
 - D. Pneumonectomy, bilobectomy, lobectomy

- E. Conservative treatment
145. Where is performed the drainage of pleural space in pyopneumothorax?
- A. *II intercostal space, midclavicular line and VII intercostal space, scapular line simultaneously
 - B. II intercostal space, midclavicular line
 - C. II intercostal space, scapular line
 - D. VII intercostal space, midclavicular line
 - E. VII intercostal space, scapular line
146. What is the early complication of chest trauma?
- A. *Pneumothorax
 - B. Posttraumatic pneumonia
 - C. Posttraumatic pleurisy
 - D. Lung abscess
 - E. Pleural empyema
147. What is the early complication of chest trauma?
- A. *Hemothorax
 - B. Lung abscess
 - C. Pleural empyema
 - D. Posttraumatic pneumonia
 - E. Posttraumatic pleurisy
148. What is the early complication of chest trauma?
- A. *Traumatic shock
 - B. Lung abscess
 - C. Pleural empyema
 - D. Posttraumatic pneumonia
 - E. Posttraumatic pleurisy
149. What is the late complication of chest trauma?
- A. *Pleural empyema
 - B. Pneumothorax
 - C. Hemothorax
 - D. Mediastinal emphysema
 - E. Traumatic shock, asphyxia
150. What is the late complication of chest trauma?
- A. *Posttraumatic pneumonia
 - B. Pneumothorax
 - C. Hemothorax
 - D. Mediastinal emphysema
 - E. Traumatic shock, asphyxia
151. What is the chief clinical manifestation of noncomplicated rib fracture?
- A. *Pain
 - B. Dyspnea
 - C. Hemoptysis
 - D. Shock
 - E. Vomiting
152. What is revealed in noncomplicated rib fracture by auscultation?
- A. *Diminished vesicular breathing
 - B. The breathing isn't auscultated
 - C. Amphoric breathing with moist rales
 - D. Bronchial breathing with moist rales
 - E. Harsh breathing with dry rales
153. What kind of X-ray picture is typical for noncomplicated rib fracture?
- A. *Break in continuity of bone fragments of ribs
 - B. Exudate in pleural space
 - C. Collapse of the lung

- D. Lung atelectasis
 - E. Heterogeneous lung shadow with destruction
154. What is the chief clinical manifestation of floating rib fracture?
- A. *Shock
 - B. Pain
 - C. Dyspnea
 - D. Hemoptysis
 - E. Vomiting
155. What is the chief objective sign of floating rib fracture?
- A. *Paradoxical respiratory movements of chest
 - B. Crepitation of ribs
 - C. Hematoma of the chest wall
 - D. Hemoptysis
 - E. Subcutaneous emphysema
156. What is revealed in floating rib fracture by auscultation?
- A. *Diminished vesicular breathing
 - B. The breathing isn't auscultated
 - C. Amphoric breathing with moist rales
 - D. Bronchial breathing with moist rales
 - E. Harsh breathing with dry rales
157. What kind of X-ray picture is typical for floating rib fracture?
- A. *Multiple rib fracture with deformity of the chest
 - B. Lung emphysema
 - C. Spheric shadow of the lung
 - D. Lung atelectasis
 - E. Heterogeneous lung shadow with destruction
158. What is the typical treatment of noncomplicated rib fracture?
- A. *Novocaine block
 - B. External fixation of ribs
 - C. Intramedullary costal osteosynthesis;
 - D. Mechanical ventilation with positive end-expiratory pressure
 - E. Thoracotomy
159. What is the first aid of floating rib fracture?
- A. *Fixation of floating segment
 - B. Analgesics
 - C. Spasmolytics
 - D. Hemostatic drugs
 - E. Antibiotics
160. What is the main treatment of floating rib fracture?
- A. *Skeletal extraction
 - B. Pleural puncture
 - C. Pneumonectomy
 - D. Resection of lung
 - E. Decortication of lung
161. What is the main treatment of floating rib fracture?
- A. *Intramedullary costal osteosynthesis
 - B. Pleural puncture
 - C. Pneumonectomy
 - D. Resection of lung
 - E. Decortication of lung
162. What is the main treatment of floating rib fracture?
- A. *Mechanical ventilation with positive end-expiratory pressure
 - B. Pleural puncture
 - C. Pneumonectomy

- D. Resection of lung
 - E. Decortication of lung
163. What type of Novocaine block is used for the treatment of floating rib fracture?
- A. *Vagosympathetic block
 - B. Paraneprhal block
 - C. Spinal block
 - D. Epidural anesthesia
 - E. Lung root dlock
164. What type of Novocaine block is used for the treatment of floating rib fracture?
- A. *Alcohol - novocaine block of the site of fracture
 - B. Paraneprhal block
 - C. Spinal block
 - D. Epidural anesthesia
 - E. Lung root dlock
165. What type of Novocaine block is used for the treatment of floating rib fracture?
- A. *Paravertebral block
 - B. Paraneprhal block
 - C. Spinal block
 - D. Epidural anesthesia
 - E. Lung root dlock
166. Partial pneumothorax means:
- A. *Collapse of lung to 1/3 of its volume
 - B. No collapse of lung
 - C. Collapse of lung to 2/3 of its volume
 - D. Collapse of lung more than 2/3 of its volume
 - E. Total collapse of lung
167. Subtotal pneumothorax means:
- A. *Collapse of lung to 2/3 of its volume
 - B. No collapse of lung
 - C. Collapse of lung to 1/3 of its volume
 - D. Collapse of lung more than 2/3 of its volume
 - E. Total collapse of lung
168. Total pneumothorax means:
- A. *Collapse of lung more than 2/3 of its volume
 - B. No collapse of lung
 - C. Collapse of lung to 1/3 of its volume
 - D. Collapse of lung to 2/3 of its volume
 - E. Collapse of lung to 1/2 of its volume
169. The collapse of lung in pneumothorax from 1/3 to 2/3 of its volume is called:
- A. *Subtotal pneumothorax
 - B. Partial pneumothorax
 - C. Total pneumothorax
 - D. Bilateral pneumothorax
 - E. Paradoxal pneumothorax
170. The collapse of lung in pneumothorax less than 1/3 of its volume is called:
- A. *Partial pneumothorax
 - B. Subtotal pneumothorax
 - C. Total pneumothorax
 - D. Bilateral pneumothorax
 - E. Paradoxal pneumothorax
171. The collapse of lung in pneumothorax more than 2/3 of its volume is called:
- A. *Total pneumothorax
 - B. Partial pneumothorax
 - C. Subtotal pneumothorax

- D. Bilateral pneumothorax
 - E. Paradoxal pneumothorax
172. What is the most dangerous pneumothorax?
- A. *Valvular
 - B. Subtotal closed
 - C. Total closed
 - D. Subtotal open
 - E. Total open
173. What is the chief clinical manifestation of pneumothorax?
- A. *Dyspnea
 - B. Vomiting
 - C. Hemoptysis
 - D. Shock
 - E. Heart failure
174. What is the chief manifestation of valvular pneumothorax?
- A. *Shock
 - B. Vomiting
 - C. Melena
 - D. Hemoptysis
 - E. Heart failure
175. What is the chief clinical manifestation of pneumothorax?
- A. *Chest pain
 - B. Vomiting
 - C. Hemoptysis
 - D. Melena
 - E. Heart failure
176. What is revealed in pneumothorax by percussion?
- A. *Bandbox sound over the whole lung
 - B. Pulmonary sound
 - C. Blunted sound over the whole lung
 - D. Metallic ringing
 - E. Blunt sound over the region of collapsed lung
177. The bandbox sound by percussion is typical for:
- A. *Pneumothorax
 - B. Lung gangrene
 - C. Pneumonia
 - D. Pleural empyema
 - E. Lung abscess
178. What is revealed in pneumothorax by auscultation?
- A. *The breathing isn't auscultated
 - B. Vesicular breathing
 - C. Amphoric breathing with moist rales
 - D. Bronchial breathing with moist rales
 - E. Harsh breathing with dry rales
179. The absence of breathing sound by auscultation is typical for:
- A. *Pneumothorax
 - B. Chronic bronchitis
 - C. Pneumonia
 - D. Lung emphyzema
 - E. Lung abscess
180. What is revealed in pneumothorax by X-ray?
- A. *Lung collapse
 - B. Lung atelectasis
 - C. Rounded cavity with air-fluid level

- D. Intensive homogeneous shadow in a basal parts with horizontal upper contour
E. Intensive homogeneous shadow in a basal parts with oblique upper contour
181. The lung collapse by X-ray is typical for:
A. *Pneumothorax
B. Chronic bronchitis
C. Pneumonia
D. Lung emphyzema
E. Lung abscess
182. The lung collapse by X-ray is typical for:
A. *Pneumothorax
B. Lung cancer
C. Pneumonia
D. Tuberculosis
E. Lung empyema
183. What is the treatment of partial pneumothorax?
A. *Pleural puncture
B. Pleural drainage
C. Thoracotomy
D. Pneumonectomy, bilobectomy, lobectomy
E. Conservative treatment
184. What is the treatment of subtotal and total pneumothorax?
A. *Pleural drainage
B. Pleural puncture
C. Thoracotomy
D. Pneumonectomy, bilobectomy, lobectomy
E. Conservative treatment
185. The pleural drainage is used for the treatment of:
A. *Pneumothorax
B. Chronic bronchitis
C. Pneumonia
D. Lung emphyzema
E. Lung abscess
186. The pleural drainage is used for the treatment of:
A. *Pyopneumothorax
B. Chronic bronchitis
C. Pneumonia
D. Lung emphyzema
E. Lung abscess
187. The pleural drainage is used for the treatment of:
A. *Pleural empyema
B. Chronic bronchitis
C. Pneumonia
D. Lung emphyzema
E. Lung abscess
188. What is the first aid in closed pneumothorax?
A. *It doesn't require first aid measures
B. Pleural drainage
C. Compression bandage with closure of the wound
D. Artificial respiration
E. Intubation
189. What is the first aid in open pneumothorax?
A. *Compression bandage with closure of the wound
B. It doesn't require first aid measures
C. Pleural drainage

- D. Artificial respiration
 - E. Intubation
190. What is the first aid in valvular pneumothorax?
- A. *Pleural drainage (to transform into open)
 - B. It doesn't require first aid measures
 - C. Compression bandage with closure of the wound
 - D. Artificial respiration
 - E. Intubation
191. Where the drainage of pleural space in pneumothorax is performed?
- A. *II intercostal space, midclavicular line
 - B. II intercostal space, scapular line
 - C. IV intercostal space, anterior axillary line
 - D. VII intercostal space, midclavicular line
 - E. VII intercostal space, scapular line
192. The pleural drainage in II intercostal space along midclavicular line is used for the treatment of:
- A. *Pneumothorax
 - B. Pleural empyema
 - C. Pneumonia
 - D. Pleurisy
 - E. Hemothorax
193. The pleural drainage in VII intercostal space along scapular line is used for the treatment of:
- A. *Pleural empyema
 - B. Pneumothorax
 - C. Chronic bronchitis
 - D. Pneumonia
 - E. Lung emphysema
194. What is the indication for operative treatment of pneumothorax?
- A. *Valvular
 - B. Subtotal closed
 - C. Total closed
 - D. Subtotal open
 - E. Total open
195. The small hemothorax means:
- A. *Loss less 10 % of volume of circulating blood
 - B. Loss of 10-20 % of volume of circulating blood
 - C. Loss of 20-40 % of volume of circulating blood
 - D. Loss of 40-60 % of volume of circulating blood
 - E. Loss more than 60 % of volume of circulating blood
196. The moderate hemothorax means:
- A. *Loss of 10-20 % of volume of circulating blood
 - B. Loss less 10 % of volume of circulating blood
 - C. Loss of 20-40 % of volume of circulating blood
 - D. Loss of 40-60 % of volume of circulating blood
 - E. Loss more than 60 % of volume of circulating blood
197. The great hemothorax means:
- A. *Loss of 20-40 % of volume of circulating blood
 - B. Loss less 10 % of volume of circulating blood
 - C. Loss of 10-20 % of volume of circulating blood
 - D. Loss of 40-60 % of volume of circulating blood
 - E. Loss more than 60 % of volume of circulating blood
198. The total hemothorax means:
- A. *Loss more than 40 % of volume of circulating blood
 - B. Loss of 20-30 % of volume of circulating blood

- C. Loss less 10 % of volume of circulating blood
 - D. Loss of 10-20 % of volume of circulating blood
 - E. Loss of 30-40 % of volume of circulating blood
199. The bloodloss to 10 % of volume of circulating blood relates to:
- A. *Small hemothorax
 - B. Moderate hemothorax
 - C. Great hemothorax
 - D. Total hemothorax
 - E. Coagulated hemothorax
200. The bloodloss of 10-20 % of volume of circulating blood relates to:
- A. *Moderate hemothorax
 - B. Small hemothorax
 - C. Great hemothorax
 - D. Total hemothorax
 - E. Coagulated hemothorax
201. The bloodloss of 20-40 % of volume of circulating blood relates to:
- A. *Great hemothorax
 - B. Moderate hemothorax
 - C. Small hemothorax
 - D. Total hemothorax
 - E. Coagulated hemothorax
202. The bloodloss more than 40 % of volume of circulating blood relates to:
- A. *Total hemothorax
 - B. Moderate hemothorax
 - C. Small hemothorax
 - D. Great hemothorax
 - E. Coagulated hemothorax
203. What is the chief clinical manifestation of hemothorax?
- A. *Clinic of internal bleeding
 - B. Pain
 - C. Vomiting
 - D. Hemoptysis
 - E. Intoxication
204. What is revealed in hemothorax by percussion?
- A. *Blunted sound
 - B. Clear sound
 - C. Bandbox sound
 - D. Tympanic sound
 - E. Metallic ringing
205. The blunted sound by percussion is typical for:
- A. *Hemothorax
 - B. Bronchitis
 - C. Lung emphysema
 - D. Pneumothorax
 - E. Lung cyst
206. The absence of breathing sounds by auscultation is typical for:
- A. *Hemothorax
 - B. Bronchitis
 - C. Lung emphysema
 - D. Lung abscess
 - E. Pneumonia
207. What is revealed in hemothorax by auscultation?
- A. *The breathing isn't auscultated
 - B. Vesicular breathing

- C. Amphoric breathing with moist rales
 - D. Bronchial breathing with moist rales
 - E. Harsh breathing with dry rales
208. What is revealed in hemothorax by X-ray?
- A. *Intensive homogeneous shadow in a basal parts with oblique upper contour
 - B. Lung atelectasis
 - C. Rounded shadow with irregular contour
 - D. Rounded cavity with air-fluid level
 - E. Intensive homogeneous shadow in a basal parts with horizontal upper contour
209. Where is the level of the X-ray shadow in small hemothorax?
- A. *Shadow observed only in the region of sinus
 - B. Up to scapular angle
 - C. Up to III rib
 - D. Complete shadow of a pleural space
 - E. The shadow is absent
210. Where is the level of the X-ray shadow in moderate hemothorax?
- A. *Up to scapular angle
 - B. Shadow observed only in the region of sinus
 - C. Up to III rib
 - D. Complete shadow of a pleural space
 - E. The shadow is absent
211. Where is the level of the X-ray shadow in great hemothorax?
- A. *Up to III rib
 - B. Shadow observed only in the region of sinus
 - C. Up to scapular angle
 - D. Complete shadow of a pleural space
 - E. The shadow is absent
212. Where is the level of the X-ray shadow in total hemothorax?
- A. *Complete shadow of a pleural space
 - B. Up to scapular angle
 - C. Shadow observed only in the region of sinus
 - D. Up to III rib
 - E. The shadow is absent
213. The X-ray shadow in hemothorax observed only in the region of sinus relates to:
- A. *Small hemothorax
 - B. Moderate hemothorax
 - C. Great hemothorax
 - D. Total hemothorax
 - E. Coagulated hemothorax
214. The X-ray shadow in hemothorax up to scapular angle relates to:
- A. *Moderate hemothorax
 - B. Small hemothorax
 - C. Great hemothorax
 - D. Total hemothorax
 - E. Coagulated hemothorax
215. The X-ray shadow in hemothorax up to III rib relates to:
- A. *Great hemothorax
 - B. Small hemothorax
 - C. Moderate hemothorax
 - D. Total hemothorax
 - E. Coagulated hemothorax
216. The complete X-ray shadow of a pleural space in hemothorax relates to:
- A. *Total hemothorax
 - B. Small hemothorax

- C. Moderate hemothorax
 - D. Great hemothorax
 - E. Coagulated hemothorax
217. What method is the most informative in differential diagnostic of hemothorax with pleurisy?
- A. *Pleural puncture
 - B. Clinical manifestation
 - C. Sputum analysis
 - D. Auscultation
 - E. X-ray examination
218. What method is the most informative in the diagnostic of hemothorax?
- A. *Pleural puncture
 - B. General blood analysis
 - C. Sputum analysis
 - D. Auscultation
 - E. X-ray examination
219. What is the sign of continuity of pleural bleeding?
- A. *The property of pleural blood to form the clot
 - B. Data of general blood analysis
 - C. Data of biochemical blood analysis
 - D. Data of coagulogram
 - E. Clinical manifestation
220. What test is used to determine the continuity of pleural bleeding?
- A. *Revilour-Gregar's test
 - B. Troyanov-Trendelenburg's test
 - C. Talman's test
 - D. Mayo-Pratt's test
 - E. Delbe-Pertess test (marching test)
221. The Revilour-Gregar's test is used in the diagnostics of:
- A. *Pleural bleeding
 - B. Lung abscess
 - C. Pleural empyema
 - D. Pneumothorax
 - E. Deep vein thrombosis
222. The property of pleural blood to form the clot is called:
- A. *Revilour-Gregar's test
 - B. Troyanov-Trendelenburg's test
 - C. Talman's test
 - D. Mayo-Pratt's test
 - E. Delbe-Pertess test (marching test)
223. What sign shows that the pleural bleeding is stopped?
- A. *The pleural blood doesn't form the clot
 - B. Data of general blood analysis
 - C. Data of biochemical blood analysis
 - D. Data of coagulogram
 - E. Clinical manifestation
224. What does the clotted hemothorax result in?
- A. *Pleural empyema
 - B. Dyspnea
 - C. Hemoptysis
 - D. Obliteration of pleural space
 - E. Cardiac tamponade
225. What kind of hemothorax is treated by pleural aspiration?
- A. *Small
 - B. Great

- C. Total
 - D. Clotted
 - E. Continuing hemothorax
226. What medicine used for the treatment of hemothorax?
- A. *Aminocapronic acid
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
227. What medicine used for the treatment of hemothorax?
- A. *Calcium chloridi
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
228. What medicine used for the treatment of hemothorax?
- A. *Dicinon
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
229. What medicine used for the treatment of hemothorax?
- A. *Vitamin K
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
230. What pathology is the indication for operative treatment?
- A. *Great and total hemothorax
 - B. Noncomplicated rib fracture
 - C. Closed partial pneumothorax
 - D. Closed total pneumothorax
 - E. Subcutaneous emphysema
231. What pathology is the indication for operative treatment?
- A. *Clotted hemothorax
 - B. Noncomplicated rib fracture
 - C. Subcutaneous emphysema
 - D. Closed partial pneumothorax
 - E. Closed total pneumothorax
232. What pathology is the indication for operative treatment?
- A. *Continuing hemothorax
 - B. Closed partial pneumothorax
 - C. Closed total pneumothorax
 - D. Noncomplicated rib fracture
 - E. Subcutaneous emphysema
233. What is the main cause of mediastinal emphysema?
- A. *Disruptions of trachea, bronchi
 - B. Rib fracture
 - C. Pneumothorax
 - D. Hemothorax
 - E. Mediastinal tumours
234. What does the mediastinal emphysema result in?
- A. *Cardiac tamponade
 - B. Hemoptysis

- C. Pleural empyema
 - D. Pneumothorax
 - E. Lung atelectasis
235. What is the treatment of mediastinal emphysema?
- A. *Drainage of anterior mediastinum
 - B. Conservative treatment
 - C. Drainage of pleural cavity
 - D. Novocaine block
 - E. Pericardial puncture
236. Where is located the first anatomical narrowing of esophagus?
- A. *The site of pharyngoesophageal junction
 - B. The site of crossing with left bronchus
 - C. The site of crossing with aorta
 - D. The site of passing through diaphragm
 - E. The site of cardia
237. Where is located the second anatomical narrowing of esophagus?
- A. *The site of crossing with left bronchus
 - B. The site of pharyngoesophageal junction
 - C. The site of crossing with aorta
 - D. The site of passing through diaphragm
 - E. The site of cardia
238. Where is located the third anatomical narrowing of esophagus?
- A. *The site of passing through diaphragm
 - B. The site of pharyngoesophageal junction
 - C. The site of crossing with aorta
 - D. The site of crossing with left bronchus
 - E. The site of cardia
239. Where is located the first physiological narrowing of esophagus?
- A. *The site of crossing with aorta
 - B. The site of pharyngoesophageal junction
 - C. The site of crossing with left bronchus
 - D. The site of passing through diaphragm
 - E. The site of cardia
240. Where is located the second physiological narrowing of esophagus?
- A. *The site of cardia
 - B. The site of pharyngoesophageal junction
 - C. The site of crossing with aorta
 - D. The site of crossing with left bronchus
 - E. The site of passing through diaphragm
241. The site of pharyngoesophageal junction is:
- A. *The first anatomical narrowing of esophagus
 - B. The second anatomical narrowing of esophagus
 - C. The third anatomical narrowing of esophagus
 - D. The first physiological narrowing of esophagus
 - E. The second physiological narrowing of esophagus
242. The site of crossing with left bronchus is:
- A. *The second anatomical narrowing of esophagus
 - B. The first anatomical narrowing of esophagus
 - C. The third anatomical narrowing of esophagus
 - D. The first physiological narrowing of esophagus
 - E. The second physiological narrowing of esophagus
243. The site of passing through diaphragm is:
- A. *The third anatomical narrowing of esophagus
 - B. The first anatomical narrowing of esophagus

- C. The second anatomical narrowing of esophagus
 - D. The first physiological narrowing of esophagus
 - E. The second physiological narrowing of esophagus
244. The site of crossing with aorta is:
- A. *The first physiological narrowing of esophagus
 - B. The first anatomical narrowing of esophagus
 - C. The second anatomical narrowing of esophagus
 - D. The third anatomical narrowing of esophagus
 - E. The second physiological narrowing of esophagus
245. The site of cardia is:
- A. *The second physiological narrowing of esophagus
 - B. The first anatomical narrowing of esophagus
 - C. The second anatomical narrowing of esophagus
 - D. The third anatomical narrowing of esophagus
 - E. The first physiological narrowing of esophagus
246. What is the mechanism of formation of pulsion diverticula?
- A. *Herniation of the esophageal wall proximal to anatomical narrowing
 - B. Inflammatory changes of paraesophageal tissues
 - C. Dilatation of esophagus caused by achalasia
 - D. Changes of esophagus caused by chemical burns
 - E. Changes of esophagus caused by reflux esophagitis
247. What is the mechanism of formation of traction diverticula?
- A. *Inflammatory changes of paraesophageal tissues
 - B. Herniation of the esophageal wall proximal to anatomical narrowing
 - C. Dilatation of esophagus caused by achalasia
 - D. Changes of esophagus caused by chemical burns
 - E. Changes of esophagus caused by reflux esophagitis
248. What sign is not typical for Zenker's diverticula?
- A. *Dyspnea
 - B. Salivation
 - C. Cervical dysphagia
 - D. Difficult swallowing
 - E. Cough
249. Zenker's diverticulum is:
- A. *Pharyngoesophageal diverticulum
 - B. Bifurcational diverticulum
 - C. Epiphrenic diverticulum
 - D. Paraaortal diverticulum
 - E. Multiple diverticula
250. What is the main objective manifestation of Zenker's diverticula?
- A. *Compressible mass on the left side of the neck
 - B. Signs of achalasia
 - C. Cyanosis of the upper part of body
 - D. Esophago-bronchial fistula with aspiration pneumonia
 - E. Lung atelectasis
251. What can bifurcational diverticula result in?
- A. *Esophago-bronchial fistula with aspiration pneumonia
 - B. Signs of achalasia
 - C. Cyanosis of the upper part of body
 - D. Compressible mass on the left side of the neck
 - E. Coarctation of aorta
252. What is the main objective manifestation of epiphrenic diverticula?
- A. *Signs of achalasia
 - B. Cyanosis of the upper part of body

- C. Compressible mass on the left side of the neck
 - D. Esophago-bronchial fistula with aspiration pneumonia
 - E. Lung atelectasis
253. For the clinical manifestation of esophageal diverticulum is typical:
- A. *Salivation
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
254. For the clinical manifestation of esophageal diverticulum is typical:
- A. *Cervical dysphagia
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
255. For the clinical manifestation of esophageal diverticulum is typical:
- A. *Difficult swallowing
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
256. For the clinical manifestation of esophageal diverticulum is typical:
- A. *Compressible mass in the neck
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
257. For the clinical manifestation of esophageal diverticulum is typical:
- A. *Gurgling sound while eating
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
258. For the clinical manifestation of esophageal diverticulum is typical:
- A. *Foul-smell from the mouth
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
259. For the clinical manifestation of esophageal diverticulum is typical:
- A. *The sign "of a wet pillow"
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
260. What is the main method of diagnostic of esophageal diverticula?
- A. *X-ray examination with barium swallow
 - B. Pleural puncture
 - C. Ultrasound examination
 - D. Plain X-ray examination of the chest
 - E. Irrigoscopy
261. What is the main method of diagnostic of esophageal diverticula?
- A. *Esophagogastroduodenoscopy
 - B. Pleural puncture

- C. Ultrasound examination
 - D. Plain X-ray examination of the chest
 - E. Irrigoscopy
262. What complication is typical for esophageal diverticula?
- A. *Bleeding
 - B. Obstructive jaundice
 - C. Intestinal obstruction
 - D. Myocardial infarction
 - E. Lung atelectasis
263. What complication is typical for esophageal diverticula?
- A. *Perforation into pleural space
 - B. Myocardial infarction
 - C. Pancreatitis
 - D. Obstructive jaundice
 - E. Intestinal obstruction
264. What complication is typical for esophageal diverticula?
- A. *Diverticulitis
 - B. Obstructive jaundice
 - C. Intestinal obstruction
 - D. Myocardial infarction
 - E. Lung atelectasis
265. What complication is typical for esophageal diverticula?
- A. *Malignancy
 - B. Obstructive jaundice
 - C. Intestinal obstruction
 - D. Myocardial infarction
 - E. Lung atelectasis
266. What disease should be the diverticulitis differentiated from?
- A. *Angina pectoris
 - B. Pancreatitis
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
267. What is the typical treatment of complicated Zenker's diverticula?
- A. *Surgical treatment
 - B. Spasmolytics
 - C. Analgetics
 - D. Nonsteroid antiinflammatory drugs
 - E. Antibiotics
268. What is the indication for conservative treatment of bifurcational diverticula?
- A. *Asymptomatic course
 - B. Frequently recurrent diverticulites
 - C. Perforation
 - D. Esophago-bronchial fistula
 - E. Suspicion on malignancy
269. What operation is performed in esophageal diverticula?
- A. *Resection of diverticulum
 - B. Esophagomyotomy
 - C. Esophagogastric anastomosis
 - D. Extirpation of esophagus
 - E. Esophageal plastics by intestine
270. What surgical access should be applied for Zenker's diverticula?
- A. *Cervical access along the anterior border of the sternocleidomastoid muscle
 - B. Left-sided anterolateral thoracotomy in IV intercostal space

- C. Right-sided posterolateral thoracotomy in IV intercostal space
 - D. Left-sided posterolateral thoracotomy in VII intercostal space
 - E. Right-sided anterolateral thoracotomy in VII intercostal space
271. What surgical access should be applied for bifurcational diverticula?
- A. *Right-sided posterolateral thoracotomy in IV intercostal space
 - B. Cervical access along the anterior border of the sternocleidomastoid muscle
 - C. Left-sided anterolateral thoracotomy in IV intercostal space
 - D. Left-sided posterolateral thoracotomy in VII intercostal space
 - E. Right-sided anterolateral thoracotomy in VII intercostal space
272. What surgical access should be applied for epiphrenal diverticula?
- A. *Left-sided posterolateral thoracotomy in VII intercostal space
 - B. Cervical access along the anterior border of the sternocleidomastoid muscle
 - C. Left-sided anterolateral thoracotomy in IV intercostal space
 - D. Right-sided posterolateral thoracotomy in IV intercostal space
 - E. Right-sided anterolateral thoracotomy in VII intercostal space
273. What is the characteristic feature of achalasia of the cardia?
- A. *Failure of the lower esophageal sphincter to relax
 - B. Spasm of the lower esophageal sphincter
 - C. Cicatrical changes after the burn
 - D. Anorexia
 - E. Esophageal gaping
274. The failure of the lower esophageal sphincter to relax is called:
- A. *Achalasia
 - B. Chaliasia
 - C. Esophageal diverticulum
 - D. Pylorostenosis
 - E. Intestinal obstruction
275. What is the cause of achalasia?
- A. *Disturbance of innervation of esophagus
 - B. Ischemia of esophagus
 - C. Tumour growth of esophagus
 - D. Diverticula of esophagus
 - E. Cicatrical changes after the burn of esophagus
276. What is the cause of achalasia?
- A. *Psycho-emotional trauma
 - B. Ischemia of esophagus
 - C. Tumour growth of esophagus
 - D. Diverticula of esophagus
 - E. Cicatrical changes after the burn of esophagus
277. What is the cause of achalasia?
- A. *Influence of vegetotrophic substances on muscular fibers
 - B. Ischemia of esophagus
 - C. Tumour growth of esophagus
 - D. Diverticula of esophagus
 - E. Cicatrical changes after the burn of esophagus
278. Who mostly suffer from achalasia?
- A. *Young women
 - B. Young men
 - C. Old men
 - D. Old women
 - E. Both old men and women
279. What is the characteristic feature of the I stage of achalasia?
- A. *Functional spasm without esophageal dilation
 - B. Asymptomatic

- C. Constant spasm with a moderate esophageal dilation and maintained peristalsis
 - D. Cicatricial changes with expressed esophageal dilation, the peristalsis is absent
 - E. Considerable esophageal dilation with S-shaped elongation.
280. What is the characteristic feature of the II stage of achalasia?
- A. *Constant spasm with a moderate esophageal dilation and maintained peristalsis
 - B. Asymptomatic
 - C. Functional spasm without esophageal dilation
 - D. Cicatricial changes with expressed esophageal dilation, the peristalsis is absent
 - E. Considerable esophageal dilation with S-shaped elongation.
281. What is the characteristic feature of the III stage of achalasia?
- A. *Cicatricial changes with expressed esophageal dilation, the peristalsis is absent
 - B. Asymptomatic
 - C. Functional spasm without esophageal dilation
 - D. Constant spasm with a moderate esophageal dilation and maintained peristalsis
 - E. Considerable esophageal dilation with S-shaped elongation.
282. What is the characteristic feature of the IV stage of achalasia?
- A. *Considerable esophageal dilation with S-shaped elongation.
 - B. Cicatricial changes with expressed esophageal dilation, the peristalsis is absent
 - C. Asymptomatic
 - D. Functional spasm without esophageal dilation
 - E. Constant spasm with a moderate esophageal dilation and maintained peristalsis
283. Functional spasm without esophageal dilation relates to such stage of achalasia:
- A. *I
 - B. II
 - C. III
 - D. IV
 - E. V
284. Constant spasm with a moderate esophageal dilation and maintained peristalsis relates to such stage of achalasia:
- A. *II
 - B. I
 - C. III
 - D. IV
 - E. V
285. Cicatricial changes with expressed esophageal dilation with absent peristalsis relates to such stage of achalasia:
- A. *III
 - B. I
 - C. II
 - D. IV
 - E. V
286. Considerable esophageal dilation with S-shaped elongation relates to such stage of achalasia:
- A. *IV
 - B. I
 - C. II
 - D. III
 - E. V
287. For the clinical manifestation of esophageal achalasia is typical:
- A. *Dysphagia
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"

288. For the clinical manifestation of esophageal achalasia is typical:
- A. *Regurgitation
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
289. For the clinical manifestation of esophageal achalasia is typical:
- A. *Splashing sounds and gurgling
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
290. For the clinical manifestation of esophageal achalasia is typical:
- A. *Nocturnal cough
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
291. For the clinical manifestation of esophageal achalasia is typical:
- A. *Pain and sense of tightness in the chest
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
292. For the clinical manifestation of esophageal achalasia is typical:
- A. *Loss of weight
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
293. What does dysphagia mean?
- A. *Disturbances of swallowing
 - B. Pain behind breastbone
 - C. Absence of appetite
 - D. Esophageal vomiting
 - E. Vomiting with blood
294. What is the I stage of dysphagia?
- A. *Disturbances of solid food passage
 - B. Asymptomatic
 - C. Disturbances of semisolid food passage
 - D. Disturbances of liquid food passage
 - E. No passage of food
295. What is the II stage of dysphagia?
- A. *Disturbances of semisolid food passage
 - B. Asymptomatic
 - C. Disturbances of solid food passage
 - D. Disturbances of liquid food passage
 - E. No passage of food
296. What is the III stage of dysphagia?
- A. *Disturbances of liquid food passage
 - B. Asymptomatic
 - C. Disturbances of solid food passage
 - D. Disturbances of semisolid food passage
 - E. No passage of food

297. What is the IV stage of dysphagia?
A. *No passage of food
B. Asymptomatic
C. Disturbances of solid food passage
D. Disturbances of semisolid food passage
E. Disturbances of liquid food passage
298. Disturbances of solid food passage relates to such stage of dysphagia:
A. *I
B. II
C. III
D. IV
E. V
299. Disturbances of semisolid food passage relates to such stage of dysphagia:
A. *II
B. I
C. III
D. IV
E. V
300. Disturbances of liquid food passage relates to such stage of dysphagia:
A. *III
B. II
C. I
D. IV
E. V
301. No passage of any food relates to such stage of dysphagia:
A. *IV
B. III
C. II
D. I
E. V
302. What is the roentgenological sign of achalasia?
A. *"Rat tail" sign
B. Filling defects
C. "Niche" sign
D. "Bell" sign
E. Blunt His angle
303. What is the roentgenological sign of esophageal cancer?
A. *Filling defects
B. "Rat tail" sign
C. "Bird-beak" sign
D. "Bell" sign
E. Blunt His angle
304. "Rat tail" is the X-ray sign of:
A. *Achalasia
B. Esophageal cancer
C. Esophageal diverticulum
D. Pylorostenosis
E. Intestinal obstruction
305. "Bird-beak" is the X-ray sign of:
A. *Achalasia
B. Esophageal cancer
C. Esophageal diverticulum
D. Pylorostenosis
E. Intestinal obstruction

306. What is the main method of diagnostic of esophageal achalasia?
A. *X-ray examination with barium swallow
B. Pleural puncture
C. Ultrasound examination
D. Plain X-ray examination of the chest
E. Irrigoscopy
307. What is the main method of diagnostic of esophageal achalasia?
A. *Esophagogastroduodenoscopy
B. Pleural puncture
C. Ultrasound examination
D. Plain X-ray examination of the chest
E. Irrigoscopy
308. What is the main treatment of the I stage of achalasia?
A. *Diet, conservative treatment
B. Cardiodilatation
C. Esophagomyotomy (Heller's operation)
D. Esophagogastroanastomosis (Hellerovskiy's operation)
E. Esophageal plastics by intestine
309. What is the main treatment of the II stage of achalasia?
A. *Cardiodilatation
B. Diet, conservative treatment
C. Esophagomyotomy (Heller's operation)
D. Esophagogastroanastomosis (Hellerovskiy's operation)
E. Esophageal plastics by intestine
310. What is the main treatment of the III stage of achalasia?
A. *Esophagomyotomy (Heller's operation)
B. Diet, conservative treatment
C. Cardiodilatation
D. Esophagogastroanastomosis (Hellerovskiy's operation)
E. Esophageal plastics by intestine
311. What is the main treatment of the IV stage of achalasia?
A. *Esophagogastroanastomosis (Hellerovskiy's operation)
B. Diet, conservative treatment
C. Cardiodilatation
D. Esophagomyotomy (Heller's operation)
E. Esophageal plastics by intestine
312. Diet, conservative treatment is indicated for such stage of achalasia:
A. *I
B. II
C. III
D. IV
E. V
313. Cardiodilatation is indicated for such stage of achalasia:
A. *II
B. I
C. III
D. IV
E. V
314. Esophagomyotomy is indicated for such stage of achalasia:
A. *III
B. II
C. I
D. IV
E. V

315. Heller's operation is indicated for such stage of achalasia:
- A. *III
 - B. II
 - C. I
 - D. IV
 - E. V
316. Esophagogastronomy is indicated for such stage of achalasia:
- A. *IV
 - B. III
 - C. II
 - D. I
 - E. V
317. Hellerovskiy's operation is indicated for such stage of achalasia:
- A. *IV
 - B. III
 - C. II
 - D. I
 - E. V
318. Hellerovskiy's operation is used for the treatment of:
- A. *Esophageal achalasia
 - B. Esophageal ulcer
 - C. Esophageal diverticulum
 - D. Pylorostenosis
 - E. Intestinal obstruction
319. Esophagogastronomy is used for the treatment of:
- A. *Esophageal achalasia
 - B. Esophageal ulcer
 - C. Esophageal diverticulum
 - D. Pylorostenosis
 - E. Intestinal obstruction
320. Heller's operation is used for the treatment of:
- A. *Esophageal achalasia
 - B. Esophageal cancer
 - C. Esophageal diverticulum
 - D. Pylorostenosis
 - E. Intestinal obstruction
321. Esophagogastronomy is used for the treatment of:
- A. *Esophageal achalasia
 - B. Esophageal ulcer
 - C. Esophageal diverticulum
 - D. Pylorostenosis
 - E. Intestinal obstruction
322. Esophagomyotomy is used for the treatment of:
- A. *Esophageal achalasia
 - B. Esophageal cancer
 - C. Esophageal diverticulum
 - D. Pylorostenosis
 - E. Intestinal obstruction
323. Cardiomyotomy is used for the treatment of:
- A. *Esophageal achalasia
 - B. Esophageal cancer
 - C. Esophageal diverticulum
 - D. Pylorostenosis
 - E. Intestinal obstruction

324. Heller's operation is:
- A. *Esophagomyotomy
 - B. Resection of the stomach
 - C. Cardiodilatation
 - D. Esophagogastranastomosis
 - E. Esophageal plastics by intestine
325. Helerovsky's operation is:
- A. *Esophagogastranastomosis
 - B. Esophagomyotomy
 - C. Resection of the stomach
 - D. Cardiodilatation
 - E. Esophageal plastics by intestine
326. Esophagogastranastomosis is:
- A. *Helerovsky's operation
 - B. Heller's operation
 - C. Bilroth's operation
 - D. Cocher's operation
 - E. Lerishe's operation
327. Esophagomyotomy is:
- A. *Heller's operation
 - B. Helerovsky's operation
 - C. Bilroth's operation
 - D. Cocher's operation
 - E. Lerishe's operation
328. What is the most often cause of cicatrical esophageal stricture?
- A. *Chemical burns
 - B. Thermal burns
 - C. Radial burns
 - D. Esophagitis
 - E. Peptic ulcers
329. What is the I stage of morphological changes of esophageal burns?
- A. *Stage of acute esophagitis
 - B. Asymptomatic
 - C. Stage of chronic esophagitis
 - D. Stage of cicatrical stricture of esophagus
 - E. Stage of late complications
330. What is the II stage of morphological changes of esophageal burns?
- A. *Stage of chronic esophagitis
 - B. Asymptomatic
 - C. Stage of acute esophagitis
 - D. Stage of cicatrical stricture of esophagus
 - E. Stage of late complications
331. What is the III stage of morphological changes of esophageal burns?
- A. *Stage of cicatrical stricture of esophagus
 - B. Asymptomatic
 - C. Stage of acute esophagitis
 - D. Stage of chronic esophagitis
 - E. Stage of late complications
332. What is the IV stage of morphological changes of esophageal burns?
- A. *Stage of late complications
 - B. Asymptomatic
 - C. Stage of acute esophagitis
 - D. Stage of chronic esophagitis
 - E. Stage of cicatrical stricture of esophagus

333. What is the I degree of esophageal burns?
- A. *Superficial burn with the damage of epithelial layer of esophagus;
 - B. The burn with the damage of entire mucosa of esophagus;
 - C. The burn damage of all layers of esophagus;
 - D. The spread of postburn necrosis on paraesophageal tissue and adjacent organs.
 - E. Asymptomatic
334. What is the II degree of esophageal burns?
- A. *The burn with the damage of entire mucosa of esophagus;
 - B. Superficial burn with the damage of epithelial layer of esophagus;
 - C. The burn damage of all layers of esophagus;
 - D. The spread of postburn necrosis on paraesophageal tissue and adjacent organs.
 - E. Asymptomatic
335. What is the III degree of esophageal burns?
- A. *The burn damage of all layers of esophagus;
 - B. Superficial burn with the damage of epithelial layer of esophagus;
 - C. The burn with the damage of entire mucosa of esophagus;
 - D. The spread of postburn necrosis on paraesophageal tissue and adjacent organs.
 - E. Asymptomatic
336. What is the IV degree of esophageal burns?
- A. *The spread of postburn necrosis on paraesophageal tissue and adjacent organs.
 - B. Superficial burn with the damage of epithelial layer of esophagus;
 - C. The burn with the damage of entire mucosa of esophagus;
 - D. The burn damage of all layers of esophagus;
 - E. Asymptomatic
337. Superficial burn with the damage of epithelial layer of esophagus relates to such degree of esophageal burns:
- A. *I
 - B. II
 - C. III
 - D. IV
 - E. V
338. The burn with the damage of entire mucosa of esophagus relates to such degree of esophageal burns:
- A. *II
 - B. I
 - C. III
 - D. IV
 - E. V
339. The burn damage of all layers of esophagus relates to such degree of esophageal burns:
- A. *III
 - B. II
 - C. I
 - D. IV
 - E. V
340. The spread of postburn necrosis on paraesophageal tissue and adjacent organs relates to such degree of esophageal burns:
- A. *IV
 - B. III
 - C. II
 - D. I
 - E. V
341. How long has been the risk of esophageal bleeding after the burn?
- A. *1-2 months
 - B. 2-3 days

- C. 10-20 days
 - D. 1-2 years
 - E. 2 years and more
342. How long is formed the esophageal stricture after the burn?
- A. *1-2 years
 - B. 2-3 days
 - C. 10-20 days
 - D. 1-2 months
 - E. 2 years and more
343. What is the roentgenological sign of the esophageal burn of mild degree?
- A. *Free passage of barium with maintained peristalsis
 - B. Filling defects without peristalsis
 - C. "Rat tail" sign with stagnation of barium
 - D. "Bird-beak" sign without peristalsis
 - E. Dilated esophagus with sites of constriction and weak peristalsis
344. What is the roentgenological sign of the esophageal burn of moderate degree?
- A. *Dilated esophagus with sites of constriction and weak peristalsis
 - B. Filling defects without peristalsis
 - C. "Rat tail" sign with stagnation of barium
 - D. "Bird-beak" sign without peristalsis
 - E. Free passage of barium with maintained peristalsis
345. What is the main clinical manifestation of the esophageal burn of severe degree?
- A. *Clinic of shock
 - B. Clinic of reflux-esophagitis
 - C. Clinic of acute abdomen
 - D. Clinic of hepatic insufficiency
 - E. Clinic of respiratory insufficiency
346. What is the main method of diagnostic of esophageal stricture?
- A. *X-ray examination with barium swallow
 - B. General blood analysis
 - C. Ultrasound examination
 - D. Plain X-ray examination of the chest
 - E. Esophagogastroduodenoscopy
347. What solution is used for washing out of acid esophageal burn?
- A. *Sodium hydrocarbonatis solution
 - B. Antiseptic solution
 - C. Antibiotic solution
 - D. Glucose solution
 - E. Vinegar solution
348. What solution is used for washing out of alkaline esophageal burn?
- A. *Vinegar solution
 - B. Antiseptic solution
 - C. Antibiotic solution
 - D. Glucose solution
 - E. Sodium hydrocarbonatis solution
349. What is the main prophylaxis of esophageal stricture after the chemical burn?
- A. *Esophageal bougienage
 - B. Spasmolytics
 - C. Parenteral feeding
 - D. Pneumocompression
 - E. Gastrostomy
350. What complication is typical for esophageal burn?
- A. *Disturbances of epiglottic valve
 - B. Esophageal diverticulum

- C. Obstructive jaundice
 - D. Intestinal obstruction
 - E. Leriche's syndrome
351. What complication is typical for esophageal burn?
- A. *Pyloric stenosis
 - B. Esophageal diverticulum
 - C. Obstructive jaundice
 - D. Intestinal obstruction
 - E. Leriche's syndrome
352. What complication is typical for esophageal burn?
- A. *Esophageal stricture
 - B. Esophageal diverticulum
 - C. Obstructive jaundice
 - D. Intestinal obstruction
 - E. Leriche's syndrome
353. What complication is typical for esophageal burn?
- A. *Gastrointestinal bleeding
 - B. Esophageal diverticulum
 - C. Obstructive jaundice
 - D. Intestinal obstruction
 - E. Leriche's syndrome
354. What complication is typical for esophageal burn?
- A. *Mediastinitis
 - B. Esophageal diverticulum
 - C. Obstructive jaundice
 - D. Intestinal obstruction
 - E. Leriche's syndrome
355. What complication is typical for acute stage of esophageal burn?
- A. *Shock
 - B. Esophageal diverticulum
 - C. Obstructive jaundice
 - D. Intestinal obstruction
 - E. Leriche's syndrome
356. What complication is typical for acute stage of esophageal burn?
- A. *Renal insufficiency
 - B. Esophageal diverticulum
 - C. Obstructive jaundice
 - D. Intestinal obstruction
 - E. Leriche's syndrome
357. What kind of operation is performed for liquidation of esophageal stricture?
- A. *Esophageal plastic
 - B. Esophagostomy
 - C. Gastrostomy
 - D. Resection of the esophagus
 - E. Resection of the stomach
358. What kind of esophageal plastic doesn't exist?
- A. *Retroperitoneal
 - B. Subcutaneous
 - C. Retrosternal
 - D. Intrapleural
 - E. Mediastinal
359. What organ is used for esophageal plastic?
- A. *Large intestine
 - B. Part of vein

- C. Prosthetic graft
 - D. Xenotransplantat
 - E. Lyophilized esophagus
360. What is the predominant manifestations of sliding diaphragmatic hernia?
- A. *Reflux-esophagitis
 - B. Achalasia
 - C. Dysphagia
 - D. Cardiospasm
 - E. Pylorostenosis
361. What is the chief clinical manifestations of reflux-esophagitis?
- A. *Heartburn
 - B. Achalasia
 - C. Dysphagia
 - D. Vomiting
 - E. Coughing
362. For the clinical manifestation of sliding diaphragmatic hernia is typical:
- A. *Pain behind breastbone
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
363. For the clinical manifestation of sliding diaphragmatic hernia is typical:
- A. *Heartburn
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
364. For the clinical manifestation of sliding diaphragmatic hernia is typical:
- A. *Belching by air
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
365. For the clinical manifestation of sliding diaphragmatic hernia is typical:
- A. *Regurgitation
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
366. For the clinical manifestation of sliding diaphragmatic hernia is typical:
- A. *The sign of "lacing shoes"
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
367. For the clinical manifestation of sliding diaphragmatic hernia is typical:
- A. *Nausea and vomiting
 - B. Dyspnea
 - C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
368. For the clinical manifestation of sliding diaphragmatic hernia is typical:
- A. *Dysphagia
 - B. Dyspnea

- C. Cyanosis of the upper part of body
 - D. Retention of stool and gases
 - E. Vomiting by "coffee masses"
369. What is the roentgenological sign of sliding diaphragmatic hernia?
- A. *Blunt His angle
 - B. Filling defects
 - C. "Rat tail" sign
 - D. "Bird-beak" sign
 - E. Esophageal dilatation
370. What is the roentgenological sign of sliding diaphragmatic hernia?
- A. *Lack of air bubble of the stomach
 - B. Esophageal dilatation
 - C. Filling defects
 - D. "Rat tail" sign
 - E. "Bird-beak" sign
371. What is the roentgenological sign of sliding diaphragmatic hernia?
- A. *"Bell" sign
 - B. "Rat tail" sign
 - C. Filling defects
 - D. "Bird-beak" sign
 - E. Esophageal dilatation
372. "Bell"-sign is the X-ray sign of:
- A. *Sliding diaphragmatic hernia
 - B. Achalasia
 - C. Esophageal diverticulum
 - D. Pylorostenosis
 - E. Intestinal obstruction
373. Lack of air bubble of the stomach is the X-ray sign of:
- A. *Sliding diaphragmatic hernia
 - B. Achalasia
 - C. Esophageal diverticulum
 - D. Pylorostenosis
 - E. Intestinal obstruction
374. Blunt His angle is the X-ray sign of:
- A. *Sliding diaphragmatic hernia
 - B. Achalasia
 - C. Esophageal diverticulum
 - D. Pylorostenosis
 - E. Intestinal obstruction
375. What is the typical clinic of paraesophageal diaphragmatic hernia?
- A. *Asymptomatic
 - B. Achalasia
 - C. Dysphagia
 - D. Pylorostenosis
 - E. Reflux-esophagitis
376. What is the most often complication of paraesophageal diaphragmatic hernia?
- A. *Strangulation
 - B. Bleeding
 - C. Dysphagia
 - D. Pylorostenosis
 - E. Reflux-esophagitis
377. What is the most often complication of sliding diaphragmatic hernia?
- A. *Bleeding
 - B. Strangulation

- C. Dysphagia
 - D. Pylorostenosis
 - E. Reflux-esophagitis
378. What is the most often complication of sliding diaphragmatic hernia?
- A. *Peptic stricture of esophagus
 - B. Strangulation
 - C. Dysphagia
 - D. Pylorostenosis
 - E. Reflux-esophagitis
379. What is the most often complication of sliding diaphragmatic hernia?
- A. *Malignancy
 - B. Strangulation
 - C. Dysphagia
 - D. Pylorostenosis
 - E. Reflux-esophagitis
380. What drugs are used for suppression of gastric secretion?
- A. *Blockers of proton pump
 - B. Spasmolytics
 - C. Adrenoblockers
 - D. Blockers of calcium channel
 - E. Anticoagulants
381. What drugs are used for suppression of gastric secretion?
- A. *H2-histamin blockers
 - B. Spasmolytics
 - C. Adrenoblockers
 - D. Blockers of calcium channel
 - E. Anticoagulants
382. What drugs are used for suppression of gastric secretion?
- A. *Omeprasol, Nexium
 - B. Ceftriaxon, Ciprinol
 - C. Euphyllin, No-spa
 - D. Nicotine acid, Heparin
 - E. Dextrin, Venoplant
383. What drugs are used for suppression of gastric secretion?
- A. *Lansa, Ultop
 - B. Ceftriaxon, Ciprinol
 - C. Euphyllin, No-spa
 - D. Nicotine acid, Heparin
 - E. Dextrin, Venoplant
384. What drugs are used for suppression of gastric secretion?
- A. *Esomeprasol, Omez
 - B. Ceftriaxon, Ciprinol
 - C. Euphyllin, No-spa
 - D. Nicotine acid, Heparin
 - E. Dextrin, Venoplant
385. What drugs are used for suppression of gastric secretion?
- A. *Quamatel, Ranitidin
 - B. Ceftriaxon, Ciprinol
 - C. Euphyllin, No-spa
 - D. Nicotine acid, Heparin
 - E. Dextrin, Venoplant
386. What drugs belong to blockers of proton pump?
- A. *Esomeprasol, Omez
 - B. Ceftriaxon, Ciprinol

- C. Euphyllin, No-spa
 - D. Nicotine acid, Heparin
 - E. Detrex, Venoplast
387. What drugs belong to blockers of proton pump?
- A. *Lansa, Ultop
 - B. Ceftriaxon, Ciprinol
 - C. Euphyllin, No-spa
 - D. Nicotine acid, Heparin
 - E. Detrex, Venoplast
388. What drugs belong to blockers of proton pump?
- A. *Omeprasol, Nexium
 - B. Ceftriaxon, Ciprinol
 - C. Euphyllin, No-spa
 - D. Nicotine acid, Heparin
 - E. Detrex, Venoplast
389. What drugs belong to H₂-histamin blockers?
- A. *Quamatel, Ranitidin
 - B. Ceftriaxon, Ciprinol
 - C. Euphyllin, No-spa
 - D. Nicotine acid, Heparin
 - E. Detrex, Venoplast
390. Quamatel, Ranitidin belong to:
- A. *H₂-histamin blockers
 - B. Blockers of proton pump
 - C. Adrenoblockers
 - D. Blockers of calcium channel
 - E. Anticoagulants
391. Omeprasol, Nexium belong to:
- A. *Blockers of proton pump
 - B. H₂-histamin blockers
 - C. Adrenoblockers
 - D. Blockers of calcium channel
 - E. Anticoagulants
392. Lansan, Ultop belong to:
- A. *Blockers of proton pump
 - B. H₂-histamin blockers
 - C. Adrenoblockers
 - D. Blockers of calcium channel
 - E. Anticoagulants
393. What disease should be the sliding diaphragmatic hernia differentiated from?
- A. *Angina pectoris
 - B. Pancreatitis
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
394. What disease should be the sliding diaphragmatic hernia differentiated from?
- A. *Peptic ulcer
 - B. Pancreatitis
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
395. What disease should be the sliding diaphragmatic hernia differentiated from?
- A. *Lung atelectasis
 - B. Pancreatitis

- C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
396. What disease should be the sliding diaphragmatic hernia differentiated from?
- A. *Pleurisy
 - B. Pancreatitis
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
397. What disease should be the sliding diaphragmatic hernia differentiated from?
- A. *Pneumonia
 - B. Pancreatitis
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
398. What disease should be the sliding diaphragmatic hernia differentiated from?
- A. *Hypochromic anemia
 - B. Pancreatitis
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
399. What is the main treatment of sliding diaphragmatic hernia?
- A. *Conservative treatment
 - B. Esophagostomy
 - C. Esophageal plastic
 - D. Resection of the esophagus
 - E. Resection of the stomach
400. What is the main treatment of sliding diaphragmatic hernia?
- A. *Cruroplasty with Nissen's fundoplication
 - B. Esophagostomy
 - C. Esophageal plastic
 - D. Resection of the esophagus
 - E. Resection of the stomach
401. What type of operation is used for paraesophageal diaphragmatic hernia?
- A. *Cruroplasty
 - B. Esophagostomy
 - C. Resection of the esophagus
 - D. Resection of the stomach
 - E. Cruroplasty with Nissen's fundoplication
402. What type of operation is used for sliding diaphragmatic hernia?
- A. *Cruroplasty with Nissen's fundoplication
 - B. Esophagostomy
 - C. Cruroplasty
 - D. Resection of the esophagus
 - E. Resection of the stomach
403. Cruroplasty with Nissen's fundoplication is used for the treatment of:
- A. *Sliding diaphragmatic hernia
 - B. Esophageal achalasia
 - C. Esophageal cancer
 - D. Esophageal diverticulum
 - E. Pylorostenosis
404. Nissen's fundoplication is used for prevention of:
- A. *Reflux-esophagitis
 - B. Intestinal obstruction

- C. Esophageal cancer
 - D. Esophageal diverticulum
 - E. Pylorostenosis
405. For prevention of reflux-esophagitis is used:
- A. *Nissen's fundoplication
 - B. Hellerovskiy's operation
 - C. Heller's operation
 - D. Cocher's operation
 - E. Lerishe's operation
406. What is the roentgenological sign of diaphragmatic relaxation?
- A. *High standing of diaphragmatic dome
 - B. Filling defect
 - C. "Rat tail" sign
 - D. Sign of "nishe"
 - E. Pneumoperitoneum
407. What is the X-ray sign of diaphragmatic relaxation?
- A. *Restriction of diaphragmatic excursion
 - B. Filling defect
 - C. "Rat tail" sign
 - D. Sign of "nishe"
 - E. Pneumoperitoneum
408. What is the X-ray sign of diaphragmatic relaxation?
- A. *Inflection of abdominal part of esophagus
 - B. Filling defect
 - C. "Rat tail" sign
 - D. Sign of "nishe"
 - E. Pneumoperitoneum
409. What disease should be the diaphragmatic relaxation differentiated from?
- A. *Diaphragmatic elevation
 - B. Pancreatitis
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
410. What disease should be the diaphragmatic relaxation differentiated from?
- A. *Pneumothorax
 - B. Pancreatitis
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
411. What disease should be the diaphragmatic relaxation differentiated from?
- A. *Pyopneumothorax
 - B. Pancreatitis
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
412. What disease should be the diaphragmatic relaxation differentiated from?
- A. *Pleurisy
 - B. Pancreatitis
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
413. What disease should be the diaphragmatic relaxation differentiated from?
- A. *Diaphragmatic hernia
 - B. Pancreatitis

- C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
414. What disease should be the diaphragmatic relaxation differentiated from?
- A. *Esophageal cancer
 - B. Pancreatitis
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
415. What operation is performed for diaphragmatic relaxation?
- A. *Phrenoplasty
 - B. Esophagomyotomy
 - C. Cruroplasty
 - D. Cruroplasty with Nissen's fundoplication
 - E. Esophageal plastics by intestine
416. Phrenoplasty is used for the treatment of:
- A. *Diaphragmatic relaxation
 - B. Sliding diaphragmatic hernia
 - C. Esophageal achalasia
 - D. Esophageal diverticulum
 - E. Pylorostenosis
417. What is the cause of acute mediastinitis?
- A. *Perforation of esophagus
 - B. Ischemia of esophagus
 - C. Tumour growth of esophagus
 - D. Diverticula of esophagus
 - E. Cicatricial changes after the burn of esophagus
418. What is the cause of acute mediastinitis?
- A. *Chemical burns of esophagus
 - B. Ischemia of esophagus
 - C. Tumour growth of esophagus
 - D. Diverticula of esophagus
 - E. Cicatricial changes after the burn of esophagus
419. What is the cause of acute mediastinitis?
- A. *Injuries of trachea
 - B. Ischemia of esophagus
 - C. Tumour growth of esophagus
 - D. Diverticula of esophagus
 - E. Cicatricial changes after the burn of esophagus
420. What is the cause of acute mediastinitis?
- A. *Injuries of bronchi
 - B. Ischemia of esophagus
 - C. Tumour growth of esophagus
 - D. Diverticula of esophagus
 - E. Cicatricial changes after the burn of esophagus
421. For the clinical manifestation of acute mediastinitis is typical:
- A. F. *Hectic temperature
 - B. G. Vomiting
 - C. H. Retention of stool and gases
 - D. Portal hypertension
 - E. J. Obstructive jaundice
422. For the clinical manifestation of acute mediastinitis is typical:
- A. *Dyspnea
 - B. Vomiting

- C. Retention of stool and gases
 - D. Portal hypertension
 - E. Obstructive jaundice
423. For the clinical manifestation of acute mediastinitis is typical:
- A. *Profuse sweating
 - B. Vomiting
 - C. Retention of stool and gases
 - D. Portal hypertension
 - E. Obstructive jaundice
424. For the clinical manifestation of acute mediastinitis is typical:
- A. *Dysphagia
 - B. Vomiting
 - C. Retention of stool and gases
 - D. Portal hypertension
 - E. Obstructive jaundice
425. For the clinical manifestation of acute mediastinitis is typical:
- A. *Constant cough
 - B. Vomiting
 - C. Retention of stool and gases
 - D. Portal hypertension
 - E. Obstructive jaundice
426. For the clinical manifestation of acute mediastinitis is typical:
- A. *Hoarseness
 - B. Vomiting
 - C. Retention of stool and gases
 - D. Portal hypertension
 - E. Obstructive jaundice
427. For the clinical manifestation of acute mediastinitis is typical:
- A. *Change of cardiac rhythm
 - B. Vomiting
 - C. Retention of stool and gases
 - D. Portal hypertension
 - E. Obstructive jaundice
428. The fever to 39-40°C is typical for:
- A. *Acute mediastinitis
 - B. Sliding diaphragmatic hernia
 - C. Esophageal achalasia
 - D. Esophageal cancer
 - E. Esophageal diverticulum
429. The dyspnea is typical for:
- A. *Acute mediastinitis
 - B. Sliding diaphragmatic hernia
 - C. Esophageal achalasia
 - D. Esophageal cancer
 - E. Esophageal diverticulum
430. The chest pain is typical for:
- A. *Acute mediastinitis
 - B. Sliding diaphragmatic hernia
 - C. Esophageal achalasia
 - D. Esophageal cancer
 - E. Esophageal diverticulum
431. The severe intoxication is typical for:
- A. *Acute mediastinitis
 - B. Sliding diaphragmatic hernia

- C. Esophageal achalasia
 - D. Esophageal cancer
 - E. Esophageal diverticulum
432. The dysphagia is typical for:
- A. *Acute mediastinitis
 - B. Bronchitis
 - C. Lung emphysema
 - D. Pulmonary hypertension
 - E. Lung cyst
433. What is the roentgenological sign of acute mediastinitis?
- A. *Widening of mediastinum, shadowing of its anterior
 - B. Filling defect
 - C. The sign of "bell"
 - D. Lack of air bubble of the stomach
 - E. High standing of diaphragmatic dome
434. What sign is typical for anterior mediastinitis?
- A. *Intensifying of pain during percussion of breast bone
 - B. Throbbing chest pain with irradiation in interscapular region
 - C. Intensifying of pain during vertebral pressing
 - D. Intensifying of pain at swallowing
 - E. Sign of compression of azygos and hemiazygos veins
435. What sign is typical for anterior mediastinitis?
- A. *Intensifying of pain when head is unbent back
 - B. Throbbing chest pain with irradiation in interscapular region
 - C. Intensifying of pain at swallowing
 - D. Swelling above clavicle
 - E. Sign of compression of azygos and hemiazygos veins
436. What sign is typical for anterior mediastinitis?
- A. *Signs of compression of superior vena cava
 - B. Throbbing chest pain with irradiation in interscapular region
 - C. Intensifying of pain at swallowing
 - D. Swelling above clavicle
 - E. Sign of compression of azygos and hemiazygos veins
437. What sign is typical for posterior mediastinitis?
- A. *Throbbing chest pain with irradiation in interscapular region
 - B. Intensifying of pain during percussion of breast bone
 - C. Intensifying of pain when head is unbent back
 - D. Occurrence of swelling in the region of jugular fossa
 - E. Signs of compression of superior vena cava
438. What sign is typical for posterior mediastinitis?
- A. *Intensifying of pain during vertebral pressing
 - B. Intensifying of pain during percussion of breast bone
 - C. Intensifying of pain when head is unbent back
 - D. Occurrence of swelling in the region of jugular fossa
 - E. Signs of compression of superior vena cava
439. What sign is typical for posterior mediastinitis?
- A. *Sign of compression of azygos and hemiazygos veins
 - B. Intensifying of pain during percussion of breast bone
 - C. Intensifying of pain when head is unbent back
 - D. Occurrence of swelling in the region of jugular fossa
 - E. Signs of compression of superior vena cava
440. What disease should be the acute mediastinitis differentiated from?
- A. *Pyopneumothorax
 - B. Diaphragmatic hernia

- C. Intestinal obstruction
 - D. Cholecystitis
 - E. Esophageal achalasia
441. What disease should be the acute mediastinitis differentiated from?
- A. *Acute pneumonia
 - B. Diaphragmatic hernia
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Esophageal achalasia
442. What disease should be the acute mediastinitis differentiated from?
- A. *Pleural empyema
 - B. Diaphragmatic hernia
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Esophageal achalasia
443. What disease should be the acute mediastinitis differentiated from?
- A. *Exsudative pericarditis
 - B. Diaphragmatic hernia
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Esophageal achalasia
444. What operation is performed for acute mediastinitis?
- A. *Mediastinotomy
 - B. Esophagomyotomy
 - C. Thoracotomy
 - D. Laparotomy
 - E. Phrenoplasty
445. Mediastinotomy is used for the treatment of:
- A. *Acute mediastinitis
 - B. Sliding diaphragmatic hernia
 - C. Esophageal achalasia
 - D. Esophageal diverticulum
 - E. Pylorostenosis
446. Which of the following statements about microalbuminuria is true?
- A. To be of clinical value, microalbuminuria must be measured in a time 12- to 24-hour
 - B. *Microalbuminuria is a cardiovascular risk factor that is independent of traditional Framingham risk factors
 - C. Microalbuminuria is a predictor of risk only in patients with diabetes
 - D. Microalbuminuria is present when the “spot” urine albumin-to-creatinine ration is >500 mg/l
 - E. All of the above statements are correct
447. All of the following are associated with hyperviscosity in the setting of Eisenmenger's syndrome except:
- A. *Coronary artery ectasia
 - B. Erythrocytosis
 - C. Visual disturbances
 - D. Paresthesias
 - E. Thrombosis and bleeding
448. All of the following physical examination findings are usually associated with ostium Secundary except:
- A. Precordial heave
 - B. Fixed split S2
 - C. *Lateral and inferior displacement of the apex beat
 - D. Soft systolic ejection murmur in the second left intercostal space

- E. Normal S1
449. All of the following statements regarding patent ductus arteriosus (PDA) are true except:
- A. *The majority of cases close spontaneously after infancy
 - B. There is a higher incidence in mothers who acquired rubella during pregnancy
 - C. A decrease in the duration and intensity of the murmur has a poor prognostic implication
 - D. Left ventricular hypertrophy precedes RV hypertrophy
 - E. If it is uncorrected, approximately one third of patients die by the age of 40 years
450. Congenital MR is commonly encountered in all of the following conditions except:
- A. *Cor triatriatum
 - B. Ostium primum ASD
 - C. Coarctation of the aorta
 - D. Congenitally corrected TGA
 - E. Subaortic stenosis
451. Coronary sinus ASD is commonly associated with...
- A. Supravalvular aortic stenosis
 - B. Supravalvular pulmonic stenosis
 - C. Cleft mitral valve
 - D. Anomalous pulmonary venous drainage
 - E. *Left superior vena cava
452. Each of the following statements regarding splitting of the second heart sound is true except:
- A. Severe pulmonic valvular stenosis is associated with a softened P2
 - B. Delayed closure of the pulmonic valve with inspiration contributes to physiologic splitting of S2
 - C. Fixed splitting of S2 is the auscultatory hallmark of an ostium Secondary atrial septal defect
 - D. Paradoxical splitting of S2 is expected in patients with a right ventricular electronically paced rhythm
 - E. *Right bundle branch block is associated with paradoxical splitting of S2
453. In which of the following cases is surgical correction recommended?
- A. Asymptomatic small VSD to decrease risk of endocarditis
 - B. PDA with severe pulmonary hypertension
 - C. *Asymptomatic subaortic stenosis with severe aortic valve insufficiency
 - D. Coarctation of the aorta with a transcoarctation gradient of 20 mmHg item
 - E. Small ASD to prevent paradoxical embolization
454. Which adult congenital disorder corresponds to the following physical examination findings: wide pulse pressure, prominent LV impulse, and a continuous machinery murmur enveloping S2
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. *Patent ductus arteriosus
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
455. Which congenital disorder corresponds with the following chest radiography findings: prominent central PAs (possible calcifications) and peripheral PA pruning?
- A. *Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
456. Which lifestyle change has been shown to produce the biggest reduction in systolic blood pressure?
- A. *10-kg weight loss
 - B. Dietary sodium reduction
 - C. Moderation of alcohol consumption

- D. Change to a vegetarian diet
 - E. Magnesium supplement
457. Which of the following syndromes is associated with pulmonary arterio-venous fistula?
- A. Williams syndrome
 - B. *Weber-Osler-Rendu syndrome
 - C. Bland-Garland-White syndrome
 - D. Kartagener's syndrome
 - E. Crouzon's syndrome
458. A 30-year-old man with Eisenmenger's syndrome and irreversible pulmonary hypertension caused by untreated VSD is at risk for developing symptoms and signs of hyperviscosity. All of the following are associated with hyperviscosity syndrome except
- A. *Coronary artery ectasia
 - B. Erythrocytosis
 - C. Visual disturbances
 - D. Paresthesias
 - E. Thrombosis and bleeding
459. A 34-year-old female with hypertension is considering becoming pregnant. Which of the following medications would be absolutely CONTRAINDICATED to control her BP during pregnancy?
- A. Methyldopa
 - B. Metoprolol
 - C. Labetalol
 - D. *Captopril
 - E. Nifedipine
460. A 48-year-old male with diabetes mellitus, hypertension, and hyperlipidemia presents to the ER with hypertensive emergency. His mean arterial pressure is 150 mmHg. Which medications would be most appropriate therapy for this patient?
- A. *Nitroprusside
 - B. Enteral metoprolol
 - C. Fenoldopam
 - D. Intravenous nitroglycerine
 - E. Any of the above
461. A young hypertensive patient has serum potassium 2.8 mEq/l and increased aldosterone level with decreased plasma renin activity. The diagnosis is:
- A. Renal artery stenosis
 - B. Ectopic ACTH syndrome
 - C. *Conn syndrome
 - D. Liddle syndrome
 - E. Cushing syndrome
462. All of the following are characteristic findings of ostium primum atrial septal defect (ASD) except:
- A. Precordial heave
 - B. Fixed split S2
 - C. *Right axis deviation
 - D. Systolic ejection murmur
 - E. Prominent pulmonary vascular markings on CXR
463. All of the following are indications for surgical closure of an ASD except:
- A. Significant symptoms in a 65-year-old
 - B. RV dysfunction
 - C. *Pulmonary vascular resistance >15
 - D. An asymptomatic 20-year-old with a Qp/Qs of 1.7 with no pulmonary hypertension
 - E. RV enlargement
464. All of the following are risk factors for hypertension, except
- A. Increased body weight

- B. Family history of hypertension
 - C. Excessive intake of sodium
 - D. *Regular use of one glass of wine per month
 - E. Cigarette smoking
465. All of the following characteristics are typical of hypertensive crisis except:
- A. Diastolic BP >120 mmHg
 - B. Retinal hemorrhages
 - C. *Constriction of cerebral arterioles with decreased vascular permeability
 - D. Proteinuria
 - E. Microangiopathic hemolytic anemia
466. ?All of the following findings are suggestive of LVH except:
- A. S in V1 + R in V5 or V6 > 35 mm
 - B. R in aVL > 11 mm
 - C. R in aVF > 20 mm
 - D. R in I + S in III > 25 mm
 - E. *R in aVR > 8 mm
467. All of the following findings are suggestive of RVH except:
- A. R in V1=7 mm (15 mm with RBBB)
 - B. R in V1 + S in V5 or V6 > 10 mm
 - C. R < S in V6
 - D. R or R' in V1
 - E. *S in V3 + R in aVL > 28 mm (20 mm for women)
468. All of the following statements concerning hypertension are true, except
- A. In a western adult population the prevalence of hypertension exceeds 20%
 - B. Hypertension is a major risk factor for cardiovascular and cerebrovascular disease
 - C. The pathophysiology of hypertension differs in black adults compared to South Asians and Europeans
 - D. *People of African descent commonly have a high renin type hypertension
 - E. An increase in potassium intake may significantly reduce blood pressure in hypertensive patients
469. All of the following statements concerning target organ damage are true except
- A. Microalbuminuria is a sensitive marker of hypertension-induced renal damage
 - B. *An increase in serum creatinine when antihypertensive therapy is intensified is a sign of progressive renal deterioration
 - C. Electrocardiography should be part of all routine assessment of subjects with high BP
 - D. Echocardiography is much more sensitive than electrocardiography in diagnosing left ventricular hypertrophy
 - E. Grades 1 and 2 arteriolar retinal changes do not have a significant prognostic value
470. All of the following statements regarding Ebstein's anomaly are true except
- A. An ASD or PFO is present in up to 80% of patients
 - B. The cardinal feature is an apically displaced tricuspid valve resulting in atrialization of ventricular tissue
 - C. WPW syndrome is common in these patients and multiple tracts can exist
 - D. *A bicuspid aortic valve is commonly present
 - E. A "sail sound" is a common finding on physical examination
471. All of the following statements regarding the effects of maneuvers on the auscultation of cardiac murmurs are true except:
- A. In patent ductus arteriosus (PDA), the diastolic phase of the murmur is intensified by isometric handgrip
 - B. *The murmur of hypertrophic obstructive cardiomyopathy becomes softer with standing or during a Valsalva strain maneuver
 - C. The murmur of a ventricular septal defect (VSD) increases with isometric handgrip
 - D. Sudden squatting or isometric handgrip increases the diastolic murmur of aortic regurgitation

- E. The mid-diastolic and presystolic murmurs of mitral stenosis become louder with exercise
472. Bacterial endocarditis prophylaxis is indicated in all adults who have the following congenital heart disease except:
- A. VSD
 - B. Coarctation of the aorta
 - C. *Secondary ASD
 - D. Hypertrophic obstructive cardiomyopathy
 - E. PDA
473. Besides pulmonary valve stenosis, which of the following is the most common associated cardiac defect present in patients with PA stenosis?
- A. *VSD
 - B. ASD
 - C. Coarctation of the aorta
 - D. PDA
 - E. Bicuspid aortic valve
474. Choose the adult congenital disorder corresponding to the following physical examination findings: wide pulse pressure, prominent LV impulse, and a continuous machinery murmur enveloping S2:
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. *Patent ductus arteriosus
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
475. Choose the adult congenital disorder corresponding to the following physical examination findings: weak or delayed femoral pulses, harsh systolic murmur in the back, and a systolic ejection click in the aortic area
- A. Eisenmenger's syndrome
 - B. *Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
476. Choose the adult congenital disorder corresponding to the following physical examination findings: RV lift with a loud systolic ejection murmur along the left sternal border, with a single S2
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. *Tetralogy of Fallot
477. Choose the adult congenital disorder corresponding to the following physical examination findings: loud S1, holosystolic murmur in left sternal border, systolic ejection click, and hepatomegaly
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. *Ebstein's anomaly
 - E. Tetralogy of Fallot
478. Choose the adult congenital disorder corresponding to the following physical examination findings: cyanosis, digital clubbing, loud P2, and a variable Graham-Steel murmur
- A. *Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly

- E. Tetralogy of Fallot
479. Choose the case in which surgical correction is recommended?
- A. Asymptomatic small VSD to decrease risk of endocarditis
 - B. PDA with severe pulmonary hypertension
 - C. *Asymptomatic subaortic stenosis with severe aortic valve insufficiency
 - D. Coarctation of the aorta with a transcoarctation gradient of 20 mmHg
 - E. Small ASD to prevent paradoxical embolization
480. Choose the congenital disorder compatible with the following chest radiography findings: posterior rib notching and a "reverse E" or "3" sign
- A. Eisenmenger's syndrome
 - B. *Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
481. Choose the congenital disorder compatible with the following chest radiography findings: pulmonary plethora, prominent ascending aorta, proximal PA dilatation, and opacity at the confluence of the aortic knob and descending aorta
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. *PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
482. Choose the congenital disorder compatible with the following chest radiography findings: marked cardiomegaly, severe right atrial enlargement, and normal lung fields
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. *Ebstein's anomaly
 - E. Tetralogy of Fallot
483. Choose the congenital disorder compatible with the following chest radiography findings: prominent central PAs (possible calcifications) and peripheral PA pruning?
- A. *Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
484. Choose the congenital disorder compatible with the following chest radiography findings: right aortic arch, RV enlargement, and a "boot-shaped" heart?
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. *Tetralogy of Fallot
485. Each of the following statements regarding the effects of maneuvers on the auscultation of cardiac murmurs is true except:
- A. Ductus arteriosus (PDA), the diastolic phase of the murmur is intensified by isometric handgrip
 - B. *The murmur of hypertrophic obstructive cardiomyopathy becomes softer with standing or during a Valsalva strain maneuver
 - C. The murmur of a ventricular septal defect (VSD) increases with isometric handgrip
 - D. Sudden squatting or isometric handgrip increases the diastolic murmur of aortic regurgitation
 - E. The mid-diastolic and presystolic murmurs of mitral stenosis become louder with exercise

486. If there is suspicion of pheochromocytoma, the first line drug is:
- A. Sodium-nitroprusside
 - B. Nifedipine
 - C. *Phentolamine
 - D. Verapamil
 - E. Enalapril
487. In patients of African descent the drug of choice for initial treatment of hypertension is:
- A. Verapamil
 - B. Atenolol
 - C. Perindopril
 - D. *Hydrochlorothiazide
 - E. Amlodipine
488. In the elderly with systolic hypertension antihypertensive therapy should be initiated if SBP
- A. 120 mmHg
 - B. 130 mmHg
 - C. 140 mmHg
 - D. *160 mmHg
 - E. 170 mmHg
489. Infective endocarditis prophylaxis is indicated in all adults who have the following congenital heart disease except:
- A. VSD
 - B. Coarctation of the aorta
 - C. *Secondary ASD
 - D. Hypertrophic obstructive cardiomyopathy
 - E. PDA
490. Noonan's syndrome is commonly associated with...
- A. Supravalvular aortic stenosis
 - B. *Supravalvular pulmonic stenosis
 - C. Cleft mitral valve
 - D. Anomalous pulmonary venous drainage
 - E. Persistent left superior vena cava
491. Of the following pairs, choose one which is incorrectly matched with the indication for therapy in hypertension?
- A. ACE inhibitor – diabetic nephropathy
 - B. Beta-blocker – coronary artery disease
 - C. Calcium channel blocker – angina pectoris
 - D. Diuretics – heart failure
 - E. *Loop diuretic – gout
492. Of the following syndromes, which one is associated with pulmonary arterio-venous fistula?
- A. Williams syndrome
 - B. *Weber-Osler-Rendu syndrome
 - C. Bland-Garland-White syndrome
 - D. Kartagener's syndrome
 - E. Crouzon's syndrome
493. Optimal blood pressure (BP) is defined as a BP level of
- A. *120/80 mmHg
 - B. 130/80 mmHg
 - C. 140/90 mmHg
 - D. 160/100 mmHg
 - E. 125/80 mmHg
494. Ostium primum ASD is commonly associated with...
- A. Supravalvular aortic stenosis
 - B. Supravalvular pulmonic stenosis
 - C. *Cleft mitral valve

- D. Anomalous pulmonary venous drainage
 - E. Persistent left superior vena cava
495. Physicians should diagnose isolated office hypertension (so-called “white-coat hypertension”) whenever office BP is $\geq 140/90$ mmHg at several visits, while 24-h ambulatory BP is
- A. 160/100 mmHg
 - B. 140/90 mmHg
 - C. 130/85 mmHg
 - D. *125/80 mmHg
 - E. 120/70 mmHg
496. Renin-dependent hypertension includes:
- A. Primary hyperaldosteronism
 - B. Essential hypertension
 - C. *Renovascular hypertension
 - D. Pheochromocytoma
 - E. Cushing syndrome
497. Sinus venosus ASD is commonly associated with...
- A. Supravalvular aortic stenosis
 - B. Supravalvular pulmonic stenosis
 - C. Cleft mitral valve
 - D. *Anomalous pulmonary venous drainage
 - E. Persistent left superior vena cava
498. Target organs in hypertension include all of the following except
- A. Brain and eyes
 - B. Heart
 - C. Kidneys
 - D. Peripheral arteries
 - E. *Liver
499. Tetralogy of Fallot includes all of the following lesions except
- A. A ventricular septal defect
 - B. An overriding aorta
 - C. *An atrial septal defect
 - D. Right ventricular outflow obstruction
 - E. Right ventricular hypertrophy
500. The best medication for the treatment of isolated systolic hypertension in the elderly:
- A. ACE-inhibitor and diuretic
 - B. *Dihydropyridine calcium-channel blocker and diuretic
 - C. Beta-blocker and diuretic
 - D. Non-dihydropyridine calcium-channel blocker and diuretic
 - E. Beta- and alpha blocker
501. The congenital mitral regurgitation is commonly encountered in all of the following conditions except:
- A. *Cor triatriatum
 - B. Ostium primum ASD
 - C. Coarctation of the aorta
 - D. Congenitally corrected TGA
 - E. Subaortic stenosis
502. The coronary sinus ASD is commonly associated with...
- A. Supravalvular aortic stenosis
 - B. Supravalvular pulmonic stenosis
 - C. Cleft mitral valve
 - D. Anomalous pulmonary venous drainage
 - E. *Persistent left superior vena cava
503. The following cardiovascular malformations are all associated with congenital rubella except:

- A. PDA
 - B. PA stenosis
 - C. *Ebstein's anomaly
 - D. Tetralogy of Fallot
 - E. Coarctation of the aorta
504. The following drug combinations are effective to treat hypertension except
- A. Diuretics + beta-blockers
 - B. Beta-blockers + dihydropyridine calcium channel blockers
 - C. Diuretics + ACE-inhibitors/ARB
 - D. ACE-inhibitors/ARB + calcium channel blockers
 - E. *Beta-blockers + ACE-inhibitors/ARB
505. The following medications can be used in pregnancy except
- A. Methyl dopa
 - B. Labetalol
 - C. *ACE-inhibitor / ARB
 - D. Hydralazine
 - E. Nifedipine
506. The following statements regarding patent ductus arteriosus (PDA) are true except:
- A. *The majority of cases close spontaneously after infancy
 - B. There is a higher incidence in mothers who acquired rubella during pregnancy
 - C. A decrease in the duration and intensity of the murmur has a poor prognostic implication
 - D. Left ventricular hypertrophy precedes RV hypertrophy
 - E. If it is uncorrected, approximately one third of patients die by the age of 40 years
507. The Noonan's syndrome is commonly associated with:
- A. Supravalvular aortic stenosis
 - B. *Supravalvular pulmonic stenosis
 - C. Cleft mitral valve
 - D. Anomalous pulmonary venous drainage
 - E. Persistent left superior vena cava
508. The ostium primum ASD is commonly associated with...
- A. Supravalvular aortic stenosis
 - B. Supravalvular pulmonic stenosis
 - C. *Cleft mitral valve
 - D. Anomalous pulmonary venous drainage
 - E. Persistent left superior vena cava
509. The ostium Secundary ASD is usually associated with the following physical examination findings except:
- A. Precordial heave
 - B. Fixed split S2
 - C. *Lateral and inferior displacement of the apex beat
 - D. Soft systolic ejection murmur in the second left intercostal space
 - E. Normal S1
510. The proportion of essential (primary) hypertension among all hypertension causes is as high as
- A. 25-30%
 - B. 40-45%
 - C. 60-65%
 - D. 70-75%
 - E. *90-95%
511. The sinus venosus ASD is commonly associated with...
- A. Supravalvular aortic stenosis
 - B. Supravalvular pulmonic stenosis
 - C. Cleft mitral valve
 - D. *Anomalous pulmonary venous drainage

- E. Persistent left superior vena cava
512. The timing of an "innocent" murmur is usually:
- A. Early systolic
 - B. Presystolic
 - C. *Midsystolic
 - D. Holosystolic
 - E. Early diastolic
513. The Williams syndrome is commonly associated with...
- A. Supravalvular aortic stenosis
 - B. *Supravalvular pulmonic stenosis
 - C. Cleft mitral valve
 - D. Anomalous pulmonary venous drainage
 - E. Persistent left superior vena cava
514. Thiazide diuretics can contribute to each of the following metabolic effects except:
- A. Hypomagnesemia
 - B. *Hypouricemia
 - C. Hypercalcemia
 - D. Hypercholesterolemia
 - E. Hyponatremia
515. What is the correct feature of the hypertensive urgency?
- A. It is always a life-threatening situation
 - B. Patient must be hospitalized
 - C. *Patients can be managed as outpatients
 - D. Therapy should not be given orally
 - E. None of the above
516. What is the most common coexisting congenital anomaly in patients with coarctation of the aorta?
- A. Cleft mitral valve
 - B. *Bicuspid aortic valve
 - C. Ebstein's anomaly
 - D. VSD
 - E. PDA
517. When present, each of the following heart sounds occurs shortly after S2 except:
- A. Opening snap
 - B. Third heart sound
 - C. *Ejection clic
 - D. Tumor plop
 - E. Pericardial knock
518. Which adult congenital disorder corresponds to the following physical examination findings: cyanosis, digital clubbing, loud P2, and a variable Graham-Steel murmur
- A. *Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
519. Which adult congenital disorder corresponds to the following physical examination findings: RV lift with a loud systolic ejection murmur along the left sternal border, with a single S2
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. *Tetralogy of Fallot
520. Which BP profile below identifies the patient with the highest risk for development of cardiovascular complications?

- A. 160/90 mmHg
 - B. *160/65 mmHg
 - C. 140/100 mmHg
 - D. 130/90 mmHg
 - E. 120/70 mmHg
521. Which condition is an absolute contraindication to pregnancy?
- A. Surgically corrected transposition of great arteries (TGA)
 - B. Congenitally corrected TGA
 - C. Ebstein's anomaly
 - D. *Eisenmenger's syndrome
 - E. Status post Fontan operation
522. Which congenital disorder corresponds with the following chest radiography findings: pulmonary plethora, prominent ascending aorta, proximal PA dilatation, and opacity at the confluence of the aortic knob and descending aorta
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. *PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
523. Which congenital disorder corresponds with the following chest radiography findings: posterior rib notching and a "reverse E" or "3" sign
- A. Eisenmenger's syndrome
 - B. *Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
524. Which congenital disorder corresponds with the following chest radiography findings: right aortic arch, RV enlargement, and a "boot-shaped" heart?
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. *Tetralogy of Fallot
525. Which congenital disorder corresponds with the following chest radiography findings: marked cardiomegaly, severe right atrial enlargement, and normal lung fields
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. *Ebstein's anomaly
 - E. Tetralogy of Fallot
526. Which lifestyle change has been shown to produce the biggest reduction in systolic blood pressure?
- A. *10-kg weight loss
 - B. Dietary sodium reduction
 - C. Moderation of alcohol consumption
 - D. Change to a vegetarian diet
 - E. Magnesium supplement
527. Which of the following is NOT a characteristic findings of ostium primum atrial septal defect (ASD)?
- A. Precordial heave
 - B. Fixed split S2
 - C. *Right axis deviation
 - D. Systolic ejection murmur
 - E. Prominent pulmonary vascular markings on CXR

528. Which of the adult congenital disorders corresponds to the following physical examination findings: weak or delayed femoral pulses, harsh systolic murmur in the back, and a systolic ejection click in the aortic area
- A. Eisenmenger's syndrome
 - B. *Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
529. Which of the adult congenital disorders corresponds to the following physical examination findings: loud S1, holosystolic murmur in left sternal border, systolic ejection click, and hepatomegaly
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. *Ebstein's anomaly
 - E. Tetralogy of Fallot
530. Which of the following antihypertensive agents is incorrectly matched with the indication for therapy?
- A. ACE inhibitor – diabetic nephropathy
 - B. Beta-blocker – coronary artery disease
 - C. Calcium channel blocker – angina pectoris
 - D. *Hydrochlorothiazide – diabetes mellitus
 - E. Loop diuretic – heart failure
531. Which of the following antihypertensive agents is incorrectly matched with the indication for therapy?
- A. ACE inhibitor – diabetic nephropathy
 - B. Beta-blocker – coronary artery disease
 - C. Calcium channel blocker – angina pectoris
 - D. Diuretics – heart failure
 - E. *Loop diuretic – gout
532. Which of the following antihypertensive agents is incorrectly matched with the indication for therapy?
- A. ACE inhibitor – diabetic nephropathy
 - B. Beta-blocker – coronary artery disease
 - C. Calcium channel blocker – angina pectoris
 - D. *Hydrochlorothiazide – diabetes mellitus
 - E. Loop diuretic – heart failure
533. Which of the following antihypertensive agents is a known cause of autoimmune hemolytic anemia?
- A. Metoprolol
 - B. *Methyldopa
 - C. Captopril
 - D. Losartan
 - E. Monoxidine
534. Which of the following cardiovascular malformations is NOT associated with congenital rubella?
- A. PDA
 - B. PA stenosis
 - C. *Ebstein's anomaly
 - D. Tetralogy of Fallot
 - E. Coarctation of the aorta
535. Which of the following diagnostic studies is most likely to demonstrate the cause of the headaches?
- A. MRI of the head

- B. MRI of the kidney
 - C. *MRI of the thorax
 - D. 24-h urinary 5-HIAA
 - E. 24-h urinary free cortisol
536. Which of the following is an absolute contraindication to pregnancy?
- A. Surgically corrected transposition of great arteries (TGA)
 - B. Congenitally corrected TGA
 - C. Ebstein's anomaly
 - D. *Eisenmenger's syndrome
 - E. Status post Fontan operation
537. Which of the following is NOT an indication for surgical closure of an ASD?
- A. Significant symptoms in a 65-year-old
 - B. RV dysfunction
 - C. *Pulmonary vascular resistance >15 Wood units that does not diminish with vasodilators
 - D. An asymptomatic 20-year-old with a Qp/Qs of 1,7 with no pulmonary hypertension
 - E. RV enlargement
538. Which of the following is the most common associated cardiac defect present in patients with pulmonary stenosis?
- A. *VSD
 - B. ASD
 - C. Coarctation of the aorta
 - D. PDA
 - E. Bicuspid aortic valve
539. Which of the following pairs of medical conditions and antihypertensive medications would be incorrect to use in a patient with essential hypertension?
- A. Beta-blocker and a history of myocardial infarction
 - B. Alpha-blocker and prostatic hypertrophy
 - C. *Thiazide diuretic and gout
 - D. Amlodipine and heart failure
 - E. ACE-inhibitor and diabetes mellitus
540. Which of the following pairs of medical conditions and antihypertensive medications would be incorrect to use in a patient with essential hypertension?
- A. Beta-blocker and a history of myocardial infarction
 - B. Alpha-blocker and prostatic hypertrophy
 - C. *Thiazide diuretic and gout
 - D. Amlodipine and heart failure
 - E. ACE-inhibitor and diabetes mellitus
541. Which of the following statements regarding antihypertensive agents and atrial fibrillation (AF) is true?
- A. *Losartan has been shown to decrease new-onset AF more effectively than atenolol
 - B. Valsartan has been shown to decrease new-onset AF more effectively than amlodipine
 - C. Atenolol has been shown to decrease new-onset AF more effectively than captopril
 - D. Nifedipine has been shown to decrease new-onset AF more effectively than diltiazem
 - E. All of the above are false
542. Which of the following statements regarding Ebstein's anomaly is NOT correct?
- A. An ASD or PFO is present in up to 80% of patients
 - B. The cardinal feature is an apically displaced tricuspid valve resulting in atrialization of ventricular tissue
 - C. WPW syndrome is common in these patients and multiple tracts can exist
 - D. *A bicuspid aortic valve is commonly present
 - E. A "sail sound" is a common finding on physical examination
543. Which of the following statements regarding prevention of stroke is correct?
- A. Treatment of systolic hypertension does not decrease the risk of stroke in patients older than age 60

- B. Hypertension should not be a target of secondary prevention after an ischemic stroke because elevated BP is desirable to maintain adequate cerebral perfusion
 - C. *Treatment with HMG-CoA reductase inhibitors reduces the risk of recurrent stroke
 - D. The combination of aspirin and clopidogrel is superior to aspirin alone for prevention of recurrent stroke
 - E. None of the above
544. Which of the following syndromes and cardiac anomalies are incorrectly matched?
- A. Trisomy 21 – atrioventricular canal defects
 - B. Noonan syndrome – pulmonic stenosis
 - C. Holt-Oram syndrome – atrial septal defects
 - D. Marfan syndrome – mitral valve prolapse
 - E. *Williams syndrome – ventricular septal defects
545. Which of these statements is true regarding renin-angiotensin system-blocking agents?
- A. Less effective when combined with a diuretic than when used alone
 - B. More effective in patients of African descent than in white patients
 - C. *Preserve kidney function in addition to lowering blood pressure
 - D. Are the first-line antihypertensive medications in pregnancy
 - E. All of the above
546. Which of these statements is true regarding renin-angiotensin system-blocking agents?
- A. Less effective when combined with a diuretic than when used alone
 - B. More effective in patients of African descent than in white patients
 - C. *Preserve kidney function in addition to lowering blood pressure
 - D. Are the first-line antihypertensive medications in pregnancy
 - E. All of the above
547. Which parameter of arterial blood pressure (BP) yields the best prognostic information in patients at risk for cardiovascular disease?
- A. Systolic BP
 - B. Diastolic BP
 - C. Mean arterial BP
 - D. *Pulse pressure
 - E. None
548. Williams syndrome is commonly associated with...
- A. Supravalvular aortic stenosis
 - B. *Supravalvular pulmonic stenosis
 - C. Cleft mitral valve
 - D. Anomalous pulmonary venous drainage
 - E. Persistent left superior vena cava
549. Thiazide diuretics can contribute to each of the following metabolic effects except:
- A. Hypomagnesemia
 - B. *Hypouricemia
 - C. Hypercalcemia
 - D. Hypercholesterolemia
 - E. Hyponatremia
550. What is the correct feature of the hypertensive urgency?
- A. It is always a life-threatening situation
 - B. Patient must be hospitalized
 - C. *Patients can be managed as outpatients
 - D. Therapy should not be given orally
 - E. None of the above
551. What is the most common coexisting congenital anomaly in patients with coarctation of the aorta?
- A. Cleft mitral valve
 - B. *Bicuspid aortic valve
 - C. Ebstein's anomaly

- D. VSD
 - E. PDA
552. When present, each of the following heart sounds occurs shortly after S2 except:
- A. Opening snap
 - B. Third heart sound
 - C. *Ejection clic
 - D. Tumor plop
 - E. Pericardial knock
553. Which adult congenital disorder corresponds to the following physical examination findings: cyanosis, digital clubbing, loud P2, and a variable Graham-Steel murmur
- A. *Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
554. Which adult congenital disorder corresponds to the following physical examination findings: RV lift with a loud systolic ejection murmur along the left sternal border, with a single S2
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. *Tetralogy of Fallot
555. Which BP profile below identifies the patient with the highest risk for development of cardiovascular complications?
- A. 160/90 mmHg
 - B. *160/65 mmHg
 - C. 140/100 mmHg
 - D. 130/90 mmHg
 - E. 120/70 mmHg
556. Which condition is an absolute contraindication to pregnancy?
- A. Surgically corrected transposition of great arteries (TGA)
 - B. Congenitally corrected TGA
 - C. Ebstein's anomaly
 - D. *Eisenmenger's syndrome
 - E. Status post Fontan operation
557. Which congenital disorder corresponds with the following chest radiography findings: pulmonary plethora, prominent ascending aorta, proximal PA dilatation, and opacity at the confluence of the aortic knob and descending aorta
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. *PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
558. Which congenital disorder corresponds with the following chest radiography findings: posterior rib notching and a "reverse E" or "3" sign
- A. Eisenmenger's syndrome
 - B. *Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
559. Which congenital disorder corresponds with the following chest radiography findings: right aortic arch, RV enlargement, and a "boot-shaped" heart?
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta

- C. PDA
 - D. Ebstein's anomaly
 - E. *Tetralogy of Fallot
560. Which congenital disorder corresponds with the following chest radiography findings: marked cardiomegaly, severe right atrial enlargement, and normal lung fields
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. *Ebstein's anomaly
 - E. Tetralogy of Fallot
561. Which lifestyle change has been shown to produce the biggest reduction in systolic blood pressure?
- A. *10-kg weight loss
 - B. Dietary sodium reduction
 - C. Moderation of alcohol consumption
 - D. Change to a vegetarian diet
 - E. Magnesium supplement
562. Which of the following is NOT a characteristic findings of ostium primum atrial septal defect (ASD)?
- A. Precordial heave
 - B. Fixed split S2
 - C. *Right axis deviation
 - D. Systolic ejection murmur
 - E. Prominent pulmonary vascular markings on CXR
563. Which of the adult congenital disorders corresponds to the following physical examination findings: weak or delayed femoral pulses, harsh systolic murmur in the back, and a systolic ejection click in the aortic area
- A. Eisenmenger's syndrome
 - B. *Coarctation of the aorta
 - C. PDA
 - D. Ebstein's anomaly
 - E. Tetralogy of Fallot
564. Which of the adult congenital disorders corresponds to the following physical examination findings: loud S1, holosystolic murmur in left sternal border, systolic ejection click, and hepatomegaly
- A. Eisenmenger's syndrome
 - B. Coarctation of the aorta
 - C. PDA
 - D. *Ebstein's anomaly
 - E. Tetralogy of Fallot
565. Which of the following antihypertensive agents is incorrectly matched with the indication for therapy?
- A. ACE inhibitor – diabetic nephropathy
 - B. Beta-blocker – coronary artery disease
 - C. Calcium channel blocker – angina pectoris
 - D. *Hydrochlorothiazide – diabetes mellitus
 - E. Loop diuretic – heart failure
566. Which of the following antihypertensive agents is incorrectly matched with the indication for therapy?
- A. ACE inhibitor – diabetic nephropathy
 - B. Beta-blocker – coronary artery disease
 - C. Calcium channel blocker – angina pectoris
 - D. Diuretics – heart failure
 - E. *Loop diuretic – gout

567. Which of the following antihypertensive agents is incorrectly matched with the indication for therapy?
- A. ACE inhibitor – diabetic nephropathy
 - B. Beta-blocker – coronary artery disease
 - C. Calcium channel blocker – angina pectoris
 - D. *Hydrochlorothiazide – diabetes mellitus
 - E. Loop diuretic – heart failure
568. Which of the following antihypertensive agents is a known cause of autoimmune hemolytic anemia?
- A. Metoprolol
 - B. *Methyldopa
 - C. Captopril
 - D. Losartan
 - E. Monoxidine
569. Which of the following cardiovascular malformations is NOT associated with congenital rubella?
- A. PDA
 - B. PA stenosis
 - C. *Ebstein's anomaly
 - D. Tetralogy of Fallot
 - E. Coarctation of the aorta
570. Which of the following diagnostic studies is most likely to demonstrate the cause of the headaches?
- A. MRI of the head
 - B. MRI of the kidney
 - C. *MRI of the thorax
 - D. 24-h urinary 5-HIAA
 - E. 24-h urinary free cortisol
571. Which of the following is an absolute contraindication to pregnancy?
- A. Surgically corrected transposition of great arteries (TGA)
 - B. Congenitally corrected TGA
 - C. Ebstein's anomaly
 - D. *Eisenmenger's syndrome
 - E. Status post Fontan operation
572. Which of the following is NOT an indication for surgical closure of an ASD?
- A. Significant symptoms in a 65-year-old
 - B. RV dysfunction
 - C. *Pulmonary vascular resistance >15 Wood units that does not diminish with vasodilators
 - D. An asymptomatic 20-year-old with a Qp/Qs of 1,7 with no pulmonary hypertension
 - E. RV enlargement
573. Which of the following is the most common associated cardiac defect present in patients with pulmonary stenosis?
- A. *VSD
 - B. ASD
 - C. Coarctation of the aorta
 - D. PDA
 - E. Bicuspid aortic valve
574. Which of the following pairs of medical conditions and antihypertensive medications would be incorrect to use in a patient with essential hypertension?
- A. Beta-blocker and a history of myocardial infarction
 - B. Alpha-blocker and prostatic hypertrophy
 - C. *Thiazide diuretic and gout
 - D. Amlodipine and heart failure
 - E. ACE-inhibitor and diabetes mellitus

575. Which of the following pairs of medical conditions and antihypertensive medications would be incorrect to use in a patient with essential hypertension?
- A. Beta-blocker and a history of myocardial infarction
 - B. Alpha-blocker and prostatic hypertrophy
 - C. *Thiazide diuretic and gout
 - D. Amlodipine and heart failure
 - E. ACE-inhibitor and diabetes mellitus
576. Which of the following statements regarding antihypertensive agents and atrial fibrillation (AF) is true?
- A. *Losartan has been shown to decrease new-onset AF more effectively than atenolol
 - B. Valsartan has been shown to decrease new-onset AF more effectively than amlodipine
 - C. Atenolol has been shown to decrease new-onset AF more effectively than captopril
 - D. Nifedipine has been shown to decrease new-onset AF more effectively than diltiazem
 - E. All of the above are false
577. Which of the following statements regarding Ebstein's anomaly is NOT correct?
- A. An ASD or PFO is present in up to 80% of patients
 - B. The cardinal feature is an apically displaced tricuspid valve resulting in atrialization of ventricular tissue
 - C. WPW syndrome is common in these patients and multiple tracts can exist
 - D. *A bicuspid aortic valve is commonly present
 - E. A "sail sound" is a common finding on physical examination
578. Which of the following statements regarding prevention of stroke is correct?
- A. Treatment of systolic hypertension does not decrease the risk of stroke in patients older than age 60
 - B. Hypertension should not be a target of secondary prevention after an ischemic stroke because elevated BP is desirable to maintain adequate cerebral perfusion
 - C. *Treatment with HMG-CoA reductase inhibitors reduces the risk of recurrent stroke
 - D. The combination of aspirin and clopidogrel is superior to aspirin alone for prevention of recurrent stroke
 - E. None of the above
579. Which of the following syndromes and cardiac anomalies are incorrectly matched?
- A. Trisomy 21 – atrioventricular canal defects
 - B. Noonan syndrome – pulmonic stenosis
 - C. Holt-Oram syndrome – atrial septal defects
 - D. Marfan syndrome – mitral valve prolapse
 - E. *Williams syndrome – ventricular septal defects
580. Which of these statements is true regarding renin-angiotensin system-blocking agents?
- A. Less effective when combined with a diuretic than when used alone
 - B. More effective in patients of African descent than in white patients
 - C. *Preserve kidney function in addition to lowering blood pressure
 - D. Are the first-line antihypertensive medications in pregnancy
 - E. All of the above
581. Which of these statements is true regarding renin-angiotensin system-blocking agents?
- A. Less effective when combined with a diuretic than when used alone
 - B. More effective in patients of African descent than in white patients
 - C. *Preserve kidney function in addition to lowering blood pressure
 - D. Are the first-line antihypertensive medications in pregnancy
 - E. All of the above
582. Which parameter of arterial blood pressure (BP) yields the best prognostic information in patients at risk for cardiovascular disease?
- A. Systolic BP
 - B. Diastolic BP
 - C. Mean arterial BP
 - D. *Pulse pressure

- E. None
583. Williams syndrome is commonly associated with...
- A. Supravalvular aortic stenosis
 - B. *Supravalvular pulmonic stenosis
 - C. Cleft mitral valve
 - D. Anomalous pulmonary venous drainage
 - E. Persistent left superior vena cava
584. One of the causes of sick sinus syndrome is:
- A. *Idiopathic degenerative fibrotic infiltration
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
585. One of the causes of sick sinus syndrome is:
- A. *Amyloidosis
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
586. One of the causes of sick sinus syndrome is:
- A. *Arteritis
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
587. One of the causes of sick sinus syndrome is:
- A. *Cardiomyopathies
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
588. One of the causes of sick sinus syndrome is:
- A. *Collagen vascular disease
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
589. One of the causes of sick sinus syndrome is:
- A. *Diphtheria
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
590. One of the causes of sick sinus syndrome is:
- A. *Familial sinoatrial node disorders
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
591. One of the causes of sick sinus syndrome is:
- A. *Fatty replacement
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia

- E. Parkinson's disease
592. One of the causes of sick sinus syndrome is:
A. *Friedreich's ataxia
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
593. One of the causes of sick sinus syndrome is:
A. *Hemochromatosis
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
594. One of the causes of sick sinus syndrome is:
A. *Myocardial infarction
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
595. One of the causes of sick sinus syndrome is:
A. *Muscular dystrophy
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
596. One of the causes of sick sinus syndrome is:
A. *Myocarditis
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
597. One of the causes of sick sinus syndrome is:
A. *Pericarditis
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
598. One of the causes of sick sinus syndrome is:
A. *Rheumatic fever
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
599. One of the causes of sick sinus syndrome is:
A. *Sarcoidosis
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
600. One of the causes of sick sinus syndrome is:
A. *Hyperkalemia
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia

- E. Parkinson's disease
601. One of the causes of sick sinus syndrome is:
A. *Digitalis intake
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
602. One of the causes of sick sinus syndrome is:
A. *Calcium channel blockers intake
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
603. One of the causes of sick sinus syndrome is:
A. *Beta blockers intake
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
604. One of the causes of sick sinus syndrome is:
A. *Sympatholytic agents intake
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
605. One of the causes of sick sinus syndrome is:
A. *Antiarrhythmics intake
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
606. One of the causes of sick sinus syndrome is:
A. *Sinoatrial nodal artery deficiency intake
B. Ulcerative diseases of stomach and duodenum
C. Aortic aneurysm
D. Cardiac achalasia
E. Parkinson's disease
607. For the clinical manifestation of sick sinus syndrome is typical:
A. *Dementia
B. Exophthalmus
C. Weight loss
D. Pain in the epigastric region
E. Profuse vomiting
608. For the clinical manifestation of sick sinus syndrome is typical:
A. *Lethargy
B. Exophthalmus
C. Weight loss
D. Pain in the epigastric region
E. Profuse vomiting
609. For the clinical manifestation of sick sinus syndrome is typical:
A. *Nocturnal wakefulness
B. Exophthalmus
C. Weight loss
D. Pain in the epigastric region

- E. Profuse vomiting
610. For the clinical manifestation of sick sinus syndrome is typical:
- A. *Lightheadedness
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region
 - E. Profuse vomiting
611. For the clinical manifestation of sick sinus syndrome is typical:
- A. *Syncope or pre-syncope
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region
 - E. Profuse vomiting
612. For the clinical manifestation of sick sinus syndrome is typical:
- A. *Angina pectoris
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region
 - E. Profuse vomiting
613. For the clinical manifestation of sick sinus syndrome is typical:
- A. *Arterial thromboemboli
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region
 - E. Profuse vomiting
614. For the clinical manifestation of sick sinus syndrome is typical:
- A. *Cerebrovascular accident
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region
 - E. Profuse vomiting
615. For the clinical manifestation of sick sinus syndrome is typical:
- A. *Congestive heart failure
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region
 - E. Profuse vomiting
616. For the clinical manifestation of sick sinus syndrome is typical:
- A. *Dementia
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region
 - E. Profuse vomiting
617. For the clinical manifestation of sick sinus syndrome is typical:
- A. *Palpitations
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region
 - E. Profuse vomiting
618. For the clinical manifestation of sick sinus syndrome is typical:
- A. *Dizziness
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region

- E. Profuse vomiting
619. What clinical sign is not typical for sick sinus syndrome:
- A. *Profuse vomiting
 - B. Nocturnal wakefulness
 - C. Syncope or pre-syncope
 - D. Congestive heart failure
 - E. Palpitations
620. What clinical sign is not typical for sick sinus syndrome:
- A. *Regurgitation
 - B. Nocturnal wakefulness
 - C. Syncope or pre-syncope
 - D. Congestive heart failure
 - E. Palpitations
621. What clinical sign is not typical for sick sinus syndrome:
- A. *Melena
 - B. Nocturnal wakefulness
 - C. Syncope or pre-syncope
 - D. Congestive heart failure
 - E. Palpitations
622. What clinical sign is not typical for sick sinus syndrome:
- A. *Defans of abdominal wall
 - B. Nocturnal wakefulness
 - C. Syncope or pre-syncope
 - D. Congestive heart failure
 - E. Palpitations
623. What clinical sign is not typical for sick sinus syndrome:
- A. *Wooden abdomen
 - B. Nocturnal wakefulness
 - C. Syncope or pre-syncope
 - D. Congestive heart failure
 - E. Palpitations
624. What clinical sign is not typical for sick sinus syndrome:
- A. *Pneumoperitoneum
 - B. Nocturnal wakefulness
 - C. Syncope or pre-syncope
 - D. Congestive heart failure
 - E. Palpitations
625. What clinical sign is not typical for sick sinus syndrome:
- A. *Vomiting by bile
 - B. Nocturnal wakefulness
 - C. Syncope or pre-syncope
 - D. Congestive heart failure
 - E. Palpitations
626. What clinical sign is not typical for sick sinus syndrome:
- A. *Exophthalmus
 - B. Nocturnal wakefulness
 - C. Syncope or pre-syncope
 - D. Congestive heart failure
 - E. Palpitations
627. What clinical sign is not typical for sick sinus syndrome:
- A. *Pain in epigastric region
 - B. Nocturnal wakefulness
 - C. Syncope or pre-syncope
 - D. Congestive heart failure

- E. Palpitations
628. What clinical sign is not typical for sick sinus syndrome:
A. *Pain in right iliac region
B. Nocturnal wakefulness
C. Syncope or pre-syncope
D. Congestive heart failure
E. Palpitations
629. What clinical sign is not typical for sick sinus syndrome:
A. *Retention of stool and gases
B. Nocturnal wakefulness
C. Syncope or pre-syncope
D. Congestive heart failure
E. Palpitations
630. What clinical sign is not typical for sick sinus syndrome:
A. *Dysphagia
B. Nocturnal wakefulness
C. Syncope or pre-syncope
D. Congestive heart failure
E. Palpitations
631. What clinical sign is not typical for sick sinus syndrome:
A. *Intermittent claudication
B. Nocturnal wakefulness
C. Syncope or pre-syncope
D. Congestive heart failure
E. Palpitations
632. What clinical sign is not typical for sick sinus syndrome:
A. *Leriche's syndrome
B. Nocturnal wakefulness
C. Syncope or pre-syncope
D. Congestive heart failure
E. Palpitations
633. What clinical sign is not typical for sick sinus syndrome:
A. *Trophic ulcers on foot
B. Nocturnal wakefulness
C. Syncope or pre-syncope
D. Congestive heart failure
E. Palpitations
634. What clinical sign is not typical for sick sinus syndrome:
A. *Toes gangrene
B. Nocturnal wakefulness
C. Syncope or pre-syncope
D. Congestive heart failure
E. Palpitations
635. What clinical sign is not typical for sick sinus syndrome:
A. *Muscular contracture of limbs
B. Nocturnal wakefulness
C. Syncope or pre-syncope
D. Congestive heart failure
E. Palpitations
636. What clinical sign is not typical for sick sinus syndrome:
A. *Cough with blood sputum
B. Nocturnal wakefulness
C. Syncope or pre-syncope
D. Congestive heart failure

- E. Palpitations
637. What clinical sign is not typical for sick sinus syndrome:
A. *Signs of hypothyroidism
B. Nocturnal wakefulness
C. Syncope or pre-syncope
D. Congestive heart failure
E. Palpitations
638. What clinical sign is not typical for sick sinus syndrome:
A. *Signs of hyperthyroidism
B. Nocturnal wakefulness
C. Syncope or pre-syncope
D. Congestive heart failure
E. Palpitations
639. What clinical sign is not typical for sick sinus syndrome:
A. *Upper lid lag when the patient looks downward
B. Nocturnal wakefulness
C. Syncope or pre-syncope
D. Congestive heart failure
E. Palpitations
640. To supraventricular bradyarrhythmia in sick sinus syndrome belongs:
A. *Sinus bradycardia
B. Paroxysmal supraventricular tachycardia
C. Atrial flutter
D. Atrial fibrillation
E. Atrial tachycardia
641. To supraventricular bradyarrhythmia in sick sinus syndrome belongs:
A. *Sinus arrest with or without junctional escape
B. Paroxysmal supraventricular tachycardia
C. Atrial flutter
D. Atrial fibrillation
E. Atrial tachycardia
642. To supraventricular bradyarrhythmia in sick sinus syndrome belongs:
A. *Sinoatrial exit block
B. Paroxysmal supraventricular tachycardia
C. Atrial flutter
D. Atrial fibrillation
E. Atrial tachycardia
643. To supraventricular bradyarrhythmia in sick sinus syndrome belongs:
A. *Ectopic atrial bradycardia
B. Paroxysmal supraventricular tachycardia
C. Atrial flutter
D. Atrial fibrillation
E. Atrial tachycardia
644. To supraventricular bradyarrhythmia in sick sinus syndrome belongs:
A. *Atrial fibrillation with slow ventricular response
B. Paroxysmal supraventricular tachycardia
C. Atrial flutter
D. Atrial fibrillation
E. Atrial tachycardia
645. To supraventricular tachyarrhythmia in sick sinus syndrome belongs:
A. *Paroxysmal supraventricular tachycardia
B. Sinus bradycardia
C. Sinus arrest with or without junctional escape
D. Sinoatrial exit block

- E. Ectopic atrial bradycardia
646. To supraventricular tachyarrhythmia in sick sinus syndrome belongs:
- A. *Atrial flutter
 - B. Sinus bradycardia
 - C. Sinus arrest with or without junctional escape
 - D. Sinoatrial exit block
 - E. Ectopic atrial bradycardia
647. To supraventricular tachyarrhythmia in sick sinus syndrome belongs:
- A. *Atrial fibrillation
 - B. Sinus bradycardia
 - C. Sinus arrest with or without junctional escape
 - D. Sinoatrial exit block
 - E. Ectopic atrial bradycardia
648. To supraventricular tachyarrhythmia in sick sinus syndrome belongs:
- A. *Atrial tachycardia
 - B. Sinus bradycardia
 - C. Sinus arrest with or without junctional escape
 - D. Sinoatrial exit block
 - E. Ectopic atrial bradycardia
649. Sick sinus syndrome with documented symptomatic bradycardia, including frequent sinus pauses that produce symptoms belongs to the such class for permanent pacemaker implantation:
- A. *I
 - B. IIa
 - C. IIb
 - D. III
 - E. IV
650. Sick sinus syndrome occurring spontaneously or as a result of necessary drug therapy, with heart rate less than 40 bpm when a clear association has not been documented belongs to the such class for permanent pacemaker implantation:
- A. *IIa
 - B. I
 - C. IIb
 - D. III
 - E. IV
651. Sick sinus syndrome in minimally symptomatic patients with chronic heart rate less than 30 bpm while awake belongs to the such class for permanent pacemaker implantation:
- A. *IIb
 - B. IIa
 - C. I
 - D. III
 - E. IV
652. Sick sinus syndrome in asymptomatic patients, including those in whom substantial sinus bradycardia (heart rate less than 40 bpm) is a consequence of long-term drug treatment belongs to the such class for permanent pacemaker implantation:
- A. *III
 - B. IIb
 - C. IIa
 - D. I
 - E. IV
653. Sick sinus syndrome with symptomatic bradycardia caused by nonessential drug therapy belongs to the such class for permanent pacemaker implantation:
- A. *III
 - B. IIb
 - C. IIa

- D. I
 - E. IV
654. Sick sinus syndrome in patients with symptoms suggestive of bradycardia that are clearly documented as not associated with a slow heart rate belongs to the such class for permanent pacemaker implantation:
- A. *III
 - B. IIb
 - C. IIa
 - D. I
 - E. IV
655. To the class I as the indications for permanent pacemaker implantation in sick sinus syndrome belong:
- A. *Sick sinus syndrome with documented symptomatic bradycardia, including frequent sinus pauses that produce symptoms
 - B. Sick sinus syndrome occurring spontaneously or as a result of necessary drug therapy, with heart rate less than 40 bpm when a clear association has not been documented
 - C. Sick sinus syndrome in minimally symptomatic patients with chronic heart rate less than 30 bpm while awake
 - D. Sick sinus syndrome with symptomatic bradycardia caused by nonessential drug therapy
 - E. Sick sinus syndrome in patients with symptoms suggestive of bradycardia that are clearly documented as not associated with a slow heart rate
656. To the class IIa as the indications for permanent pacemaker implantation in sick sinus syndrome belong:
- A. *Sick sinus syndrome occurring spontaneously or as a result of necessary drug therapy, with heart rate less than 40 bpm when a clear association has not been documented
 - B. Sick sinus syndrome with documented symptomatic bradycardia, including frequent sinus pauses that produce symptoms
 - C. Sick sinus syndrome in minimally symptomatic patients with chronic heart rate less than 30 bpm while awake
 - D. Sick sinus syndrome with symptomatic bradycardia caused by nonessential drug therapy
 - E. Sick sinus syndrome in patients with symptoms suggestive of bradycardia that are clearly documented as not associated with a slow heart rate
657. To the class IIb as the indications for permanent pacemaker implantation in sick sinus syndrome belong:
- A. *Sick sinus syndrome in minimally symptomatic patients with chronic heart rate less than 30 bpm while awake
 - B. Sick sinus syndrome with documented symptomatic bradycardia, including frequent sinus pauses that produce symptoms
 - C. Sick sinus syndrome occurring spontaneously or as a result of necessary drug therapy, with heart rate less than 40 bpm when a clear association has not been documented
 - D. Sick sinus syndrome with symptomatic bradycardia caused by nonessential drug therapy
 - E. Sick sinus syndrome in patients with symptoms suggestive of bradycardia that are clearly documented as not associated with a slow heart rate
658. To the class III as the indications for permanent pacemaker implantation in sick sinus syndrome belong:
- A. *Sick sinus syndrome with symptomatic bradycardia caused by nonessential drug therapy
 - B. Sick sinus syndrome with documented symptomatic bradycardia, including frequent sinus pauses that produce symptoms
 - C. Sick sinus syndrome occurring spontaneously or as a result of necessary drug therapy, with heart rate less than 40 bpm when a clear association has not been documented
 - D. Sick sinus syndrome in minimally symptomatic patients with chronic heart rate less than 30 bpm while awake
 - E. Sick sinus syndrome with symptomatic tachycardia

659. To the class III as the indications for permanent pacemaker implantation in sick sinus syndrome belong:
- A. *Sick sinus syndrome in patients with symptoms suggestive of bradycardia that are clearly documented as not associated with a slow heart rate
 - B. Sick sinus syndrome in minimally symptomatic patients with chronic heart rate less than 30 bpm while awake
 - C. Sick sinus syndrome with documented symptomatic bradycardia, including frequent sinus pauses that produce symptoms
 - D. Sick sinus syndrome occurring spontaneously or as a result of necessary drug therapy, with heart rate less than 40 bpm when a clear association has not been documented
 - E. Sick sinus syndrome with symptomatic tachycardia
660. To the class III as the indications for permanent pacemaker implantation in sick sinus syndrome belong:
- A. *Sick sinus syndrome in asymptomatic patients, including those in whom substantial sinus bradycardia (heart rate less than 40 bpm) is a consequence of long-term drug treatment
 - B. Sick sinus syndrome in minimally symptomatic patients with chronic heart rate less than 30 bpm while awake
 - C. Sick sinus syndrome with documented symptomatic bradycardia, including frequent sinus pauses that produce symptoms
 - D. Sick sinus syndrome occurring spontaneously or as a result of necessary drug therapy, with heart rate less than 40 bpm when a clear association has not been documented
 - E. Sick sinus syndrome with symptomatic tachycardia
661. One of the causes of AV-block of the I degree is:
- A. *Professional sport
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
662. One of the causes of AV-block is:
- A. *Myocardial infarction
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
663. One of the causes of AV-block is:
- A. *Angina pectoris
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
664. One of the causes of AV-block is:
- A. *Viral myocarditis
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
665. One of the causes of AV-block is:
- A. *Rheumatic fever
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
666. One of the causes of AV-block is:

- A. *Infectious mononucleosis
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
667. One of the causes of AV-block is:
- A. *Sarcoidosis
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
668. One of the causes of AV-block is:
- A. *Amyloidosis
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
669. One of the causes of AV-block is:
- A. *Malignant tumours
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
670. One of the causes of AV-block is:
- A. *Beta blockers intake
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
671. One of the causes of AV-block is:
- A. *Calcium channel blockers intake
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
672. One of the causes of AV-block is:
- A. *Digitalis intake
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
673. One of the causes of AV-block is:
- A. *Leva's disease
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
674. One of the causes of AV-block is:
- A. *Lenegra's disease
 - B. Ulcerative diseases of stomach and duodenum
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Parkinson's disease
675. Leva's disease is:

- A. *Idiopathic heart stroma sclerosis
 - B. Idiopathic conducting system sclerosis
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Sarcoidosis
676. Lenegra's disease is:
- A. *Idiopathic conducting system sclerosis
 - B. Idiopathic heart stroma sclerosis
 - C. Aortic aneurysm
 - D. Cardiac achalasia
 - E. Sarcoidosis
677. Idiopathic conducting system sclerosis is:
- A. *Lenegra's disease
 - B. Leva's disease
 - C. Parkinson's disease
 - D. Mobitz disease
 - E. Wenckebach disease
678. First-degree AV block is characterized by:
- A. *Prolongation of the PR interval on the ECG more than 0.20 s
 - B. Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause
 - C. Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles
 - D. No supraventricular impulses are conducted to the ventricles
 - E. Rhythm identified by atrial and ventricular activation occurring from different pacemakers
679. Mobitz I second-degree AV block is characterized by:
- A. *Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause
 - B. Prolongation of the PR interval on the ECG more than 0.20 s
 - C. Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles
 - D. No supraventricular impulses are conducted to the ventricles
 - E. Rhythm identified by atrial and ventricular activation occurring from different pacemakers
680. Wenckebach block is characterized by:
- A. *Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause
 - B. Prolongation of the PR interval on the ECG more than 0.20 s
 - C. Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles
 - D. No supraventricular impulses are conducted to the ventricles
 - E. Rhythm identified by atrial and ventricular activation occurring from different pacemakers
681. Mobitz II second-degree AV block is characterized by:
- A. *Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles
 - B. Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause
 - C. Prolongation of the PR interval on the ECG more than 0.20 s
 - D. No supraventricular impulses are conducted to the ventricles
 - E. Rhythm identified by atrial and ventricular activation occurring from different pacemakers
682. Third-degree AV block is characterized by:

- A. *No supraventricular impulses are conducted to the ventricles
 - B. Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles
 - C. Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause
 - D. Prolongation of the PR interval on the ECG more than 0.20 s
 - E. Rhythm identified by atrial and ventricular activation occurring from different pacemakers
683. AV dissociation is characterized by:
- A. *Rhythm identified by atrial and ventricular activation occurring from different pacemakers
 - B. No supraventricular impulses are conducted to the ventricles
 - C. Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles
 - D. Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause
 - E. Prolongation of the PR interval on the ECG more than 0.20 s
684. Prolongation of the PR interval on the ECG more than 0.20 s is:
- A. *First-degree AV block
 - B. Mobitz I second-degree AV block
 - C. Mobitz II second-degree AV block
 - D. Third-degree AV block
 - E. AV dissociation
685. Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause is:
- A. *Mobitz I second-degree AV block
 - B. First-degree AV block
 - C. Mobitz II second-degree AV block
 - D. Third-degree AV block
 - E. AV dissociation
686. Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause is:
- A. *Wenckebach AV block
 - B. First-degree AV block
 - C. Mobitz II second-degree AV block
 - D. Third-degree AV block
 - E. AV dissociation
687. Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles is:
- A. *Mobitz II second-degree AV block
 - B. Mobitz I second-degree AV block
 - C. First-degree AV block
 - D. Third-degree AV block
 - E. AV dissociation
688. No supraventricular impulses are conducted to the ventricles is:
- A. *Third-degree AV block
 - B. Mobitz II second-degree AV block
 - C. Mobitz I second-degree AV block
 - D. First-degree AV block
 - E. AV dissociation
689. Rhythm identified by atrial and ventricular activation occurring from different pacemakers is:
- A. *AV dissociation
 - B. Third-degree AV block

- C. Mobitz II second-degree AV block
 - D. Mobitz I second-degree AV block
 - E. First-degree AV block
690. First-degree AV block is characterized by:
- A. *Slowed AV conduction
 - B. Partial conduction of supraventricular impulses to the ventricles
 - C. Complete failure of AV conduction
 - D. Independent impulses from atriums and ventricles
 - E. Paroxysmal tachycardia
691. Second-degree AV block is characterized by:
- A. *Partial conduction of supraventricular impulses to the ventricles
 - B. Slowed AV conduction
 - C. Complete failure of AV conduction
 - D. Independent impulses from atriums and ventricles
 - E. Paroxysmal tachycardia
692. Third-degree AV block is characterized by:
- A. *Complete failure of AV conduction
 - B. Partial conduction of supraventricular impulses to the ventricles
 - C. Slowed AV conduction
 - D. Independent impulses from atriums and ventricles
 - E. Paroxysmal tachycardia
693. AV dissociation is characterized by:
- A. *Independent impulses from atriums and ventricles
 - B. Partial conduction of supraventricular impulses to the ventricles
 - C. Slowed AV conduction
 - D. Complete failure of AV conduction
 - E. Paroxysmal tachycardia
694. Slowed AV conduction is typical for:
- A. *First-degree AV block
 - B. Second-degree AV block
 - C. Third-degree AV block
 - D. AV dissociation
 - E. Paroxysmal tachycardia
695. Partial conduction of supraventricular impulses to the ventricles is typical for:
- A. *Second-degree AV block
 - B. First-degree AV block
 - C. Third-degree AV block
 - D. AV dissociation
 - E. Paroxysmal tachycardia
696. Complete failure of AV conduction is typical for:
- A. *Third-degree AV block
 - B. First-degree AV block
 - C. Second-degree AV block
 - D. AV dissociation
 - E. Paroxysmal tachycardia
697. Independent impulses from atriums and ventricles is typical for:
- A. *AV dissociation
 - B. Third-degree AV block
 - C. First-degree AV block
 - D. Second-degree AV block
 - E. Paroxysmal tachycardia
698. No supraventricular impulses are conducted to the ventricles is:
- A. *Third-degree AV block
 - B. Mobitz II second-degree AV block

- C. Mobitz I second-degree AV block
 - D. First-degree AV block
 - E. AV dissociation
699. ECG changes of the first-degree AV block are characterized by:
- A. *Prolongation of the PR interval on the ECG more than 0.20 s
 - B. Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause
 - C. Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles
 - D. No supraventricular impulses are conducted to the ventricles
 - E. Rhythm identified by atrial and ventricular activation occurring from different pacemakers
700. ECG changes of the Mobitz I second-degree AV block are characterized by:
- A. *Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause
 - B. Prolongation of the PR interval on the ECG more than 0.20 s
 - C. Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles
 - D. No supraventricular impulses are conducted to the ventricles
 - E. Rhythm identified by atrial and ventricular activation occurring from different pacemakers
701. ECG changes of the Mobitz II second-degree AV block are characterized by:
- A. *Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles
 - B. Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause
 - C. Prolongation of the PR interval on the ECG more than 0.20 s
 - D. No supraventricular impulses are conducted to the ventricles
 - E. Rhythm identified by atrial and ventricular activation occurring from different pacemakers
702. ECG changes of the third-degree AV block are characterized by:
- A. *No supraventricular impulses are conducted to the ventricles
 - B. Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles
 - C. Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause
 - D. Prolongation of the PR interval on the ECG more than 0.20 s
 - E. Rhythm identified by atrial and ventricular activation occurring from different pacemakers
703. ECG changes of the AV dissociation are characterized by:
- A. *Rhythm identified by atrial and ventricular activation occurring from different pacemakers
 - B. No supraventricular impulses are conducted to the ventricles
 - C. Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles
 - D. Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause
 - E. Prolongation of the PR interval on the ECG more than 0.20 s
704. Prolongation of the PR interval more than 0.20 s is the ECG sign of:
- A. *First-degree AV block
 - B. Mobitz I second-degree AV block
 - C. Mobitz II second-degree AV block
 - D. Third-degree AV block
 - E. AV dissociation

705. Progressive prolongation of the PR interval with the subsequent occurrence of a single nonconducted P wave that results in a pause is the ECG sign of:
- A. *Mobitz I second-degree AV block
 - B. First-degree AV block
 - C. Mobitz II second-degree AV block
 - D. Third-degree AV block
 - E. AV dissociation
706. Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles is the ECG sign of:
- A. *Mobitz II second-degree AV block
 - B. Mobitz I second-degree AV block
 - C. First-degree AV block
 - D. Third-degree AV block
 - E. AV dissociation
707. No supraventricular impulses are conducted to the ventricles is the ECG sign of:
- A. *Third-degree AV block
 - B. Mobitz II second-degree AV block
 - C. Mobitz I second-degree AV block
 - D. First-degree AV block
 - E. AV dissociation
708. Rhythm identified by atrial and ventricular activation occurring from different pacemakers is the ECG sign of:
- A. *AV dissociation
 - B. Third-degree AV block
 - C. Mobitz II second-degree AV block
 - D. Mobitz I second-degree AV block
 - E. First-degree AV block
709. For the clinical manifestation of third-degree AV block is typical:
- A. *Dizziness
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region
 - E. Profuse vomiting
710. For the clinical manifestation of third-degree AV block is typical:
- A. *Lightheadedness
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region
 - E. Profuse vomiting
711. For the clinical manifestation of third-degree AV block is typical:
- A. *Syncope or pre-syncope
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region
 - E. Profuse vomiting
712. For the clinical manifestation of third-degree AV block is typical:
- A. *Morgagni-Adams-Stokes syndrome
 - B. Exophthalmus
 - C. Weight loss
 - D. Pain in the epigastric region
 - E. Profuse vomiting
713. For the clinical manifestation of first-degree AV block is typical:
- A. *Asymptomatic course
 - B. Morgagni-Adams-Stokes syndrome

- C. Syncope or pre-syncope
 - D. Lightheadedness
 - E. Dizziness
714. For the clinical manifestation of second-degree AV block is typical:
- A. *Asymptomatic course
 - B. Morgagni-Adams-Stokes syndrome
 - C. Syncope or pre-syncope
 - D. Lightheadedness
 - E. Dizziness
715. Syncope or pre-syncope syndrome in AV block is called:
- A. *Morgagni-Adams-Stokes syndrome
 - B. Leriche's syndrome
 - C. Mobitz syndrome
 - D. Wenckebach syndrome
 - E. Leva's disease
716. Morgagni-Adams-Stokes syndrome is
- A. *Syncope or pre-syncope syndrome in AV block
 - B. Prolongation of the PR interval on the ECG more than 0.20 s
 - C. Constant PR interval followed by sudden failure of a P wave to be conducted to the ventricles
 - D. Lightheadedness in AV block
 - E. Association of AV block with myocardial infarction
717. Third-degree AV block at any anatomic level associated with bradycardia and symptoms presumed to be due to AV block belongs to the such class for permanent pacemaker implantation:
- A. *I
 - B. IIa
 - C. IIb
 - D. III
 - E. IV
718. Third-degree AV block at any anatomic level associated with arrhythmias and other medical conditions that require drugs that result in symptomatic bradycardia belongs to the such class for permanent pacemaker implantation:
- A. *I
 - B. IIa
 - C. IIb
 - D. III
 - E. IV
719. Third-degree AV block at any anatomic level associated with documented periods of asystole 3.0 seconds belongs to the such class for permanent pacemaker implantation:
- A. *I
 - B. IIa
 - C. IIb
 - D. III
 - E. IV
720. Third-degree AV block at any anatomic level associated with documented any escape rate <40 beats per minute (bpm) in awake, symptom-free patients belongs to the such class for permanent pacemaker implantation:
- A. *I
 - B. IIa
 - C. IIb
 - D. III
 - E. IV

721. Third-degree AV block at any anatomic level after catheter ablation of the AV junction belongs to the such class for permanent pacemaker implantation:
- A. *I
 - B. IIa
 - C. IIb
 - D. III
 - E. IV
722. Postoperative third-degree AV block at any anatomic level that is not expected to resolve belongs to the such class for permanent pacemaker implantation:
- A. *I
 - B. IIa
 - C. IIb
 - D. III
 - E. IV
723. Third-degree AV block at any anatomic level associated with myotonic muscular dystrophy belongs to the such class for permanent pacemaker implantation:
- A. *I
 - B. IIa
 - C. IIb
 - D. III
 - E. IV
724. Third-degree AV block at any anatomic level associated with Erb's dystrophy (limb-girdle dystrophy) belongs to the such class for permanent pacemaker implantation:
- A. *I
 - B. IIa
 - C. IIb
 - D. III
 - E. IV
725. Second-degree AV block regardless of type or site of block, with associated symptomatic bradycardia belongs to the such class for permanent pacemaker implantation:
- A. *I
 - B. IIa
 - C. IIb
 - D. III
 - E. IV
726. Asymptomatic third-degree AV block at any anatomic site with average awake ventricular rates of 40 bpm or faster belongs to the such class for permanent pacemaker implantation:
- A. *IIa
 - B. I
 - C. IIb
 - D. III
 - E. IV
727. Asymptomatic type II second-degree AV block belongs to the such class for permanent pacemaker implantation:
- A. *IIa
 - B. I
 - C. IIb
 - D. III
 - E. IV
728. Asymptomatic type I second-degree AV block at intra- or infra-His levels found incidentally at electrophysiological study for other indications belongs to the such class for permanent pacemaker implantation:
- A. *IIa
 - B. I

- C. IIb
 - D. III
 - E. IV
729. First-degree AV block with symptoms suggestive of pacemaker syndrome and documented alleviation of symptoms with temporary AV pacing belongs to the such class for permanent pacemaker implantation:
- A. *IIa
 - B. I
 - C. IIb
 - D. III
 - E. IV
730. Marked first-degree AV block (>0.30 second) in patients with LV dysfunction and symptoms of congestive heart failure in whom a shorter AV interval results in hemodynamic improvement belongs to the such class for permanent pacemaker implantation:
- A. *IIb
 - B. IIa
 - C. I
 - D. III
 - E. IV
731. Asymptomatic first-degree AV block belongs to the such class for permanent pacemaker implantation:
- A. *III
 - B. IIb
 - C. IIa
 - D. I
 - E. IV
732. Asymptomatic type I second-degree AV block at the supra-His (AV node) level belongs to the such class for permanent pacemaker implantation:
- A. *III
 - B. IIb
 - C. IIa
 - D. I
 - E. IV
733. AV block which expected to resolve and unlikely to recur (eg, drug toxicity, Lyme disease) belongs to the such class for permanent pacemaker implantation:
- A. *III
 - B. IIb
 - C. IIa
 - D. I
 - E. IV
734. A main direct danger for a patient with acute bleeding is
- A. deficit of hemoglobin
 - B. *Hypovolemia
 - C. Hypoproteinemia
 - D. coagulopathy
 - E. deficit of fibrinogen
735. A most important for the life of patient through possible transformation in ventricles fibrillation is presented by arrhythmia
- A. ventricle premature beats more than 20 in a minute
 - B. *ventricle tachycardia
 - C. arrhythmias, that unite with lengthening of intraventricular conductivity blockade of the left leg of bunch of Giss
 - D. arrhythmia
 - E. all answers are correct

736. At a patient with concomitant cardiac insufficiency acutely the expressed anemia. Which from offered remedies for transfusion prevails?
- *erithromass
 - fresh blood
 - frozen plasma
 - there are all wrong answers
 - all answers are faithful
737. Endotracheally it is possible to enter the following drugs, except for:
- noradrenalin
 - adrenalin
 - lidocain
 - atropine
 - *oxybutirat
738. A complete atrioventricular block is characterised
- by absence of conducting of impulses from an autriums to ventricles
 - by a idioventricoular rhythm
 - by the attacks Morgani - Adams - Stocs
 - all answers are faithful
 - *all answers are right
739. A doctor decided to perform the defibrillation to patient with arrhythmia, using a synchronizer. The digit of defibrillator must be synchronized:
- *with wave Q
 - with the descending phase of R
 - by an T
 - consideration of phase of ECG-complex not important
 - there is no right answer
740. A leading symptom for the diagnosis of stop of circulation of blood is:
- wide pupils, that are irresponsive on light
 - absence of consciousness
 - absence of breathing
 - *absence of pulse on a carotid
 - cyanosis
741. At anafilactic shock obligatory medicine are:
- *providing of permeability of respiratory tracts and adequate
 - imobilisation extremities
 - infousion therapy
 - analgesia
 - injection of vazopresors
742. At development of signs of toxic action of digoxinum medical treatment includes intravenous injection of
- verapamilum
 - *lidocainum
 - calcium chloride
 - all answers are wrong
 - faithful all answers
743. At which types of arrhythmia intravenous injection of potassium is effective?
- Ventricular tahycardia
 - Nodular tahycardia
 - Ventricular extrasystolia
 - Supraventricular arrhythmia
 - *At all of indicated types of arrhythmia
744. Cardiotoxic properties of hypercalciemia is taken off by application:
- Adrenalin
 - Coffeinum

- C. Ephedrine
 - D. *Molar solution of lactat natrium
 - E. 10 % solution of glucose
745. Cardiotoxicity action of hypocalcemia treated by application:
- A. adrenalin
 - B. ephedrine
 - C. *preparations of calcium
 - D. a 10% solution of glucose
 - E. corticosteroid
746. For the hypovolemia is not typical:
- A. reduction of volume of circulatory blood
 - B. decline of BP, tachycardia
 - C. reduction of shock volume and cardiac troop landing
 - D. *rise of CVP
 - E. decline of pressure of filling of the left ventricle
747. For the prophylaxis of carcinogenic shock it does not use at the acute heart attack follow
- A. beta-adrenoblocers
 - B. anaesthetizing, sedation
 - C. inhalation O₂
 - D. beta-adrenostimulators
 - E. *all answers are not complete
748. Hypotension at anaphylactic shock develops as a result of
- A. *increase of permeability of vessels and loss of volume of intravascular liquid
 - B. losses of likable tone
 - C. free prostaglandin
 - D. bradycardia
 - E. all are right
749. In the case of tamponade of heart is not observed
- A. rise of central vein pressure
 - B. *noise of systole
 - C. cyanosis
 - D. paradoxical pulse
 - E. rise of pulmonary capillary pressure
750. In the origin of hyperdynamic type of circulation of blood at patients with a sepsis, acute bleeding the following reactions take part:
- A. acute tamponade of heart
 - B. shunting of circulation
 - C. *violations of microcirculation, disorders of tissue exchange and accumulations of vasoactive metabolities
 - D. faithful all answers
 - E. there is no right answer
751. Intravenous injection of morphine at the carcinogenic edema of lungs can be attained the following positive effects:
- A. increase of irritating of myocardium
 - B. decline of retroactive power of myocardium
 - C. spasm of coronal vessels
 - D. *faithful all answers
 - E. right all answers
752. Lengthening of interval P-Q more than 0,2 sec is observed at:
- A. Fibrillation of auricles
 - B. Sine bradycardia
 - C. Alternuous pulse
 - D. *AV block 1
 - E. Bigemina

753. Medical treatment of anaphylactic shock includes first time the use of
- *adrenalin
 - antihistaminic preparations
 - neuroplegic
 - All answers are wrong
 - faithful all answers
754. Properties of blood reology are fixed:
- By viscosity of blood
 - By physical and chemical stability of suspension of uniform elements
 - By the state of vessels wall
 - *All answers are correct
 - There is no right answer
755. Signs of local myocarditis recovering are represented best of all by the changes of wave
- P
 - Q
 - T
 - *R
 - S
756. Stretched neck veins in standing position are observed at
- tamponade of heart
 - tense pneumothorax
 - to pulmonary embolism
 - *faithful all answers
 - all answers are wrong
757. The acute carcinogenic edema of lungs is conditioned most of all:
- by the rise of hydrostatical pressure in pulmonary capillaries
 - by the promoted pulmonary capillary permeability
 - *by insufficiency of the left ventricle
 - faithful all answers
 - All answers are wrong
758. The basic sign of heart death is:
- agonal complexes
 - mechanical asistolia with saving of electric systole
 - electric asistolia during 30 min, not looking on cordial - pulmonary reanimation and proper medical therapy
 - *isoelectric line on ECG during 15 min
 - all answers are faithful
759. The dosage of bicarbonate of sodium in case of stopping of heart makes:
- the first injection 1 mmol/Kg
 - the first injection 2 mmol/Kg
 - the repeated injections 0.5 meq/cg every 10 mines
 - *approximately 100 ml for each min of clinical death
 - faithful all answers
760. The forcing function of heart is supported in case:
- At wrong situation of electrodes
 - At inadequate ventilation of lungs
 - acidosis
 - When the previous massage of heart was uneffective
 - *All answers are right
761. The injection of the following medicines may prevent the attack of paroxysmal tahycardia, except of :
- *Isoproterenol
 - Mezatonum
 - Digitalis and hinidinum

- D. Metocsamium
 - E. Morphynum
762. The most expressed positive inotropic effect at cardiogenic shock is observed at injection of:
- A. noradrenalinum
 - B. *dopaminum
 - C. digocsinum
 - D. isadrinum
 - E. ephedrinum
763. The most frequent reason of embolism is:
- A. Trauma
 - B. Cardial insufficiency
 - C. Aneurism
 - D. Atherosclerosis
 - E. *Fibrillation of atrium
764. The most important ECG-sign of subendocardial myocardial ischemia is:
- A. *rise of segment S-T higher to the isoline line more than on 2 mm
 - B. decline of segment S-T below to the isoline line more than on 2 mm
 - C. inversion of T
 - D. there are all wrong answers
 - E. all answers are faithful
765. The permission to use lidocainum in the process of cardiac-pulmonary reanimation are:
- A. *fibrillation of ventricles
 - B. electro mechanics dissociation
 - C. fibrillation of atriums
 - D. right all answers
 - E. wrong all answers
766. The satisfactory oxygen capacity of blood is provided by hematocrit, not below
- A. 20-25%
 - B. *30%
 - C. 35%
 - D. 40%
 - E. 45%
767. To arrhythmias, which are accompanied by acute cardiac insufficiency, belong:
- A. fibrillation of ventricles
 - B. complete atrioventricular block
 - C. high-frequency trembling of atriums
 - D. faithful all answers
 - E. *right all answers
768. To medicines which have most vasodilatational and lowering postload, belong:
- A. nitrates
 - B. *ganglioblocers
 - C. nitroprousid
 - D. morfin
 - E. faithful all answers
769. What medicine is used for medical treatment of atrio-ventricular block III?
- A. Lidocain
 - B. Inderal
 - C. Novocainamid
 - D. *Isuprel
 - E. There is no right answer
770. What must be applied from following during haemotransfusion for saving of blood properties, that take part in coagulation?
- A. Warmed-up blood
 - B. Calcium

- C. Oxygen
 - D. Blood of two-week remoteness
 - E. *Fresh blood
771. What type of hypoxia changes greatly oxygen saturation of arterial blood ?
- A. Circulatory
 - B. Anemic
 - C. *Hypoxic
 - D. Tissue
 - E. There is no right answer
772. At medical treatment of paroxysmal tachycardia it is not prescribed to apply
- A. antagonists of beta-adrenoreceptors
 - B. electric cardioversion
 - C. pressure on a carotid sine
 - D. lidocain
 - E. *atropin
773. Characteristic signs for different types of shocks are:
- A. Oppression of consciousness
 - B. *Lowering of arterial pressure
 - C. Lowering of shock index Algovera
 - D. Lowering TSVD
 - E. Oppression of breathing
774. Choose the most optimum therapy of anaphylactic shock
- A. *Adrenalin, polyglucin, prednisolone IV
 - B. Dimedrol, prednisolon, cordiaminum, - IV
 - C. Atropin, pipolphenum, prednisolon, - IV
 - D. Polyhluvin, calcium chloride, hydrocortyson, - IV
 - E. Antihistaminic orally
775. Deep wave Q may be the sign of
- A. MI
 - B. Ischemia of myocardium
 - C. Hypokaliemia
 - D. Hyperpotassiumemia
 - E. *All answers are wrong
776. Deep wave Q may be the sign of
- A. Necrosis of myocardium
 - B. Ischemia of myocardium
 - C. Hypokaliemia
 - D. Hyperpotassiumemia
 - E. *All answers are wrong
777. Electrocardiostimulation is not prescribed at:
- A. to the complete atrioventricular block
 - B. syndrome of weakness of sine knot with the attacks Morgani-Adams-Stocs
 - C. ciliary arrhythmia with rare contraction of ventricles
 - D. *bradycardia, by the caused intoxication by cardiac glucoside
 - E. all answers are faithful
778. For cardiogenic shock is not characteristic:
- A. *Decreasing of central venous pressure
 - B. Stagnation in the small circle of blood
 - C. Low BP
 - D. Diminishing of arteriotony
 - E. Decline of diuresis
779. For treatment of pulmonary edema of cardiac origin the doctor should prescribe
- A. *Narcotic analgetic
 - B. Solution of euphyllinum

- C. Diuretic - MANNITOL
 - D. Diuretic - veroshpiron
 - E. Calcium chloride
780. Heparin behaves to the group;
- A. *Enkefalins
 - B. Endorfins
 - C. Eucasinoids
 - D. A superoxyde anion
 - E. There is no right answer
781. High vein pressure, hypotension and acute circulation insufficiency are observed in the case of:
- A. tense pneumathorax
 - B. embolisms of pulmonary artery
 - C. to vein air embolism
 - D. wrong all answers
 - E. *right all answers
782. Hypovolaemic shock is determined in:
- A. *Reduction of body weight
 - B. By the decline of hemokoncentrative indexes
 - C. By paresis of peripheral vessels
 - D. By hypoglycemia
 - E. By growth of central venous pressure
783. Medical treatment of patient with acute left side ventricular insufficiency includes
- A. ALV at the permanent promoted pressure
 - B. infusion of nitroglycerinum
 - C. inhibitor of phosphodiesterase, furosemide
 - D. all answers are faithful
 - E. *All answers are wrong
784. Medicine of choice at paroxysmal supraventricular tachycardia is:
- A. digoxin
 - B. lidocain
 - C. *isoptin
 - D. novocainamid
 - E. polarized mixture
785. Removing a pain syndrome at the urgent call concerning the acute heart attack of myocardium is possible simpler than all:
- A. *by injection of narcotic and unnarcotic analgetic
 - B. epidural analgesia
 - C. by inhalation of nitrous oxide, xenon with O₂(1:1)
 - D. there is no right answer
 - E. all answers are faithful
786. The depression of ST segment means
- A. Hypoxia of myocardium
 - B. Hypokaliemia
 - C. Hyperpotassiumemia
 - D. *Necrosis of myocardium
 - E. All answers are wrong
787. The depression of T wave may mean
- A. Hypoxia of myocardium
 - B. Fibrillation of atriums
 - C. *Hyperpotassiumemia
 - D. Necrosis of myocardium
 - E. All answers are wrong
788. The depression of T wave means

- A. Hypoxia of myocardium
 - B. Hypokaliemia
 - C. *Hyperpotassiumemia
 - D. Necrosis of myocardium
 - E. All answers are wrong
789. The elevation of ST segment means
- A. *Hypoxia of myocardium
 - B. Hypokaliemia
 - C. Hyperpotassiumemia
 - D. Necrosis of myocardium
 - E. All answers are wrong
790. The insufficiency of left ventricle can be caused :
- A. *by insufficient flow of blood to the heart
 - B. by the overload volume of blood
 - C. by the decline of refractive power of myocardium
 - D. wrong all answers
 - E. faithful all answers
791. The main ECG sign of transmural MI is
- A. Elevation of T wave
 - B. Depression of ST segment
 - C. *Pathological QS wave
 - D. Pathological S wave
 - E. All answers are wrong
792. The most important sign of acute heart attack of myocardium during anesthesia are:
- A. Hypotensia
 - B. *changes of ECG, arrhythmia
 - C. increase of pulse pressure
 - D. All answers are wrong
 - E. All answers are right
793. The stop of heart during asynchronous defibrillation is linked
- A. with direct damaging of myocardium
 - B. with the hit of impulse on the P wave of ECG
 - C. with the hit of impulse on ascending part of T wave
 - D. *with the hit of impulse on descending part of T wave
 - E. all answers are faithful
794. What assertion is incorrect for traumatic shock?
- A. *Sharp decreases of shock index
 - B. A syndrome of low cardiac ejection
 - C. Centralization of circulation of blood develops
 - D. CVP goes down
 - E. Disturbances of coagulation
795. ?What remedy does dilate veins?
- A. *Nitroglicerine
 - B. Analgin
 - C. Strophanthine
 - D. Dopamine
 - E. Anaprilin
796. What remedy does not dilate veins?
- A. Nitrosorbid
 - B. Analgin
 - C. Strophanthine
 - D. *Dopamine
 - E. Anaprilin
797. Which of medicines are most contra-indicated at ventricular tahycardia

- A. Lidocain
 - B. Propranolol
 - C. Novocainamid
 - D. *Isuprel
 - E. Metaraminol
798. Which of the following changes on ECG is typical for hypercaliemia?
- A. fibrillation of ventricles
 - B. fibrillation of auricles
 - C. *High and narrow wave T
 - D. Decline of indent T and appearance of indent V
 - E. Decline of segment S-T
799. You can use for treatment of ischemic heart disease
- A. *Nitrates
 - B. Stabisol
 - C. Manitol
 - D. Arduan
 - E. All answers are wrong
800. You will use for treatment of ischemic heart disease
- A. Sustac
 - B. Stabisol
 - C. Manitol
 - D. Arduan
 - E. *All answers are wrong
801. You will use for treatment of ischemic heart disease
- A. *Nitrong
 - B. Stabisol
 - C. Manitol
 - D. Arduan
 - E. All answers are wrong
802. What is the endemic goiter characterized by?
- A. *Goiter which occurs in biogeochemical regions with iodine deficiency in environment
 - B. Goiter which occurs in unendemic regions
 - C. Goiter lesion of both lobes
 - D. Goiter of atypical localization
 - E. Goiter with changed function
803. What is the sporadic goiter characterized by?
- A. *Goiter which occurs in unendemic regions
 - B. Goiter which occurs in biogeochemical regions with iodine deficiency in environment
 - C. Goiter lesion of both lobes
 - D. Goiter of atypical localization
 - E. Goiter with changed function
804. Goiter which occurs in biogeochemical regions with iodine deficiency in environment is called:
- A. *Endemic goiter
 - B. Sporadic goiter
 - C. Thyrotoxicosis
 - D. Myxedema
 - E. Atypical goiter
805. Goiter which occurs in unendemic regions is called:
- A. *Sporadic goiter
 - B. Endemic goiter
 - C. Thyrotoxicosis
 - D. Myxedema
 - E. Atypical goiter

806. What is the 0 degree of goiter?
A. *The thyroid gland is not palpated;
B. The isthmus of the gland is noticeable during swallowing and could be palpated;
C. Entire gland is noticeable during swallowing and could be palpated;
D. The enlargement of gland results in evident thickening of neck ("a thick neck");
E. The gland considerably enlarged, and sharply deforms neck;
807. What is the I degree of goiter?
A. *The isthmus of the gland is noticeable during swallowing and could be palpated;
B. The thyroid gland is not palpated;
C. Entire gland is noticeable during swallowing and could be palpated;
D. The enlargement of gland results in evident thickening of neck ("a thick neck");
E. The gland considerably enlarged, and sharply deforms neck;
808. What is the II degree of goiter?
A. *Entire gland is noticeable during swallowing and could be palpated;
B. The thyroid gland is not palpated;
C. The isthmus of the gland is noticeable during swallowing and could be palpated;
D. The enlargement of gland results in evident thickening of neck ("a thick neck");
E. The gland considerably enlarged, and sharply deforms neck;
809. What is the III degree of goiter?
A. *The enlargement of gland results in evident thickening of neck ("a thick neck");
B. The thyroid gland is not palpated;
C. The isthmus of the gland is noticeable during swallowing and could be palpated;
D. Entire gland is noticeable during swallowing and could be palpated;
E. The gland considerably enlarged, and sharply deforms neck;
810. What is the IV degree of goiter?
A. *The gland considerably enlarged, and sharply deforms neck;
B. The enlargement reaches excessive size (goiter of major sizes)
C. The isthmus of the gland is noticeable during swallowing and could be palpated;
D. Entire gland is noticeable during swallowing and could be palpated;
E. The enlargement of gland results in evident thickening of neck ("a thick neck");
811. What is the IV degree of goiter?
A. *The enlargement reaches excessive size (goiter of major sizes)
B. The gland considerably enlarged, and sharply deforms neck;
C. The isthmus of the gland is noticeable during swallowing and could be palpated;
D. Entire gland is noticeable during swallowing and could be palpated;
E. The enlargement of gland results in evident thickening of neck ("a thick neck");
812. What is the degree of goiter when the thyroid gland is not palpated?
A. *0
B. II
C. I
D. III
E. IV
813. What is the degree of goiter when the isthmus of the gland is noticeable during swallowing and could be palpated?
A. *I
B. V
C. II
D. III
E. IV
814. What is the degree of goiter when entire gland is noticeable during swallowing and could be palpated?
A. *I
B. II
C. V

- D. III
 - E. IV
815. What is the degree of goiter when the enlargement of gland results in evident thickening of neck ("a thick neck")?
- A. *III
 - B. I
 - C. V
 - D. II
 - E. IV
816. What is the degree of goiter when the gland considerably enlarged, and sharply deforms neck?
- A. *IV
 - B. III
 - C. I
 - D. V
 - E. II
817. What is the degree of goiter when the enlargement reaches excessive size (goiter of major sizes)?
- A. *V
 - B. IV
 - C. III
 - D. I
 - E. II
818. What is the predominant factor which causes the goiter?
- A. *Lack of iodine
 - B. Increased cholesterol, dyslipoproteinemia
 - C. Suprarenal insufficiency
 - D. Rheumatism, endocarditis
 - E. Lack of vitamin C
819. What is the contributing factor which causes the lung abscess?
- A. *Excessive calcium, deficiency of bromine in environment
 - B. Increased cholesterol, dyslipoproteinemia
 - C. Suprarenal insufficiency
 - D. Rheumatism, endocarditis
 - E. Lack of vitamin C
820. What is the contributing factor which causes the lung abscess?
- A. *Lack of cobalt, and zinc
 - B. Increased cholesterol, dyslipoproteinemia
 - C. Suprarenal insufficiency
 - D. Rheumatism, endocarditis
 - E. Lack of vitamin C
821. Goiter which localized on the back of the tongue is called:
- A. *Ectopic goiter
 - B. Aberrant goiter
 - C. Typical
 - D. Presternal
 - E. Retrosternal
822. Intrathoracic localization of goiter is called:
- A. *Ectopic goiter
 - B. Aberrant goiter
 - C. Typical
 - D. Presternal
 - E. Retrosternal
823. The goiter of additional gland is called:

- A. *Aberrant goiter
 - B. Ectopic goiter
 - C. Typical
 - D. Presternal
 - E. Retrosternal
824. Ectopic goiter is:
- A. *Dislocation of the goiter
 - B. The goiter of additional gland
 - C. The goiter with increased function
 - D. The goiter with decreased function
 - E. The goiter with normal function
825. Aberrant goiter is:
- A. *The goiter of additional gland
 - B. Dislocation of the goiter
 - C. The goiter with increased function
 - D. The goiter with decreased function
 - E. The goiter with normal function
826. What complication is characteristic for the goiter?
- A. *Strumitis
 - B. Laringospasm
 - C. Pneumothorax
 - D. Mediastinal emphysema
 - E. Atypical goiter
827. What complication is characteristic for the goiter?
- A. *Hemorrhage into the gland
 - B. Laringospasm
 - C. Pneumothorax
 - D. Mediastinal emphysema
 - E. Atypical goiter
828. What complication is characteristic for the goiter?
- A. *Malignancy
 - B. Laringospasm
 - C. Pneumothorax
 - D. Mediastinal emphysema
 - E. Atypical goiter
829. What complication is characteristic for the goiter?
- A. *Asphyxia
 - B. Laringospasm
 - C. Pneumothorax
 - D. Mediastinal emphysema
 - E. Atypical goiter
830. In case of euthyroid goiter the patient mainly complains of:
- A. *Neck deformity
 - B. Sleepiness
 - C. Hypomnesia
 - D. Excessive sweating
 - E. Tremor of arms
831. In case of euthyroid goiter the patient mainly complains of:
- A. *Difficult breathing
 - B. Sleepiness
 - C. Hypomnesia
 - D. Excessive sweating
 - E. Tremor of arms
832. In case of euthyroid goiter the patient mainly complains of:

- A. *Difficult swallowing
 - B. Sleepiness
 - C. Hypomnesia
 - D. Excessive sweating
 - E. Tremor of arms
833. In case of euthyroid goiter the patient mainly complains of:
- A. *Sudden attacks of cough
 - B. Sleepiness
 - C. Hypomnesia
 - D. Excessive sweating
 - E. Tremor of arms
834. For the clinical manifestation of retrosternal is typical:
- A. *Dyspnea
 - B. Sleepiness
 - C. Hypomnesia
 - D. Excessive sweating
 - E. Tremor of arms
835. For the clinical manifestation of retrosternal is typical:
- A. *Hoarseness
 - B. Sleepiness
 - C. Hypomnesia
 - D. Excessive sweating
 - E. Tremor of arms
836. For the clinical manifestation of retrosternal is typical:
- A. *Distended veins of neck
 - B. Sleepiness,
 - C. Hypomnesia
 - D. Excessive sweating
 - E. Tremor of arms
837. The neck deformity is a clinical manifestation of the patient with:
- A. *Euthyroid goiter
 - B. Hypothyroidism
 - C. Thyrotoxicosis
 - D. Esophageal achalasia
 - E. Empyema
838. The difficult breathing is a clinical manifestation of the patient with:
- A. *Euthyroid goiter
 - B. Hypothyroidism
 - C. Thyrotoxicosis
 - D. Esophageal achalasia
 - E. Gastric ulcer
839. The difficult swallowing is a clinical manifestation of the patient with:
- A. *Euthyroid goiter
 - B. Hypothyroidism
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Empyema
840. In case of hypothyroid goiter the patient mainly complains of:
- A. *Sleepiness
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
841. In case of hypothyroid goiter the patient mainly complains of:

- A. *General weakness
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
842. In case of hypothyroid goiter the patient mainly complains of:
- A. *Malaise
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
843. In case of hypothyroid goiter the patient mainly complains of:
- A. *Hypomnesia
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
844. In case of hypothyroid goiter the patient mainly complains of:
- A. *Dry skin
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
845. In case of hypothyroid goiter the patient mainly complains of:
- A. *Constipations
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
846. In case of hypothyroid goiter the patient mainly complains of:
- A. *Leg edemas
 - B. Difficult breathing
 - C. Neck deformity
 - D. Excessive sweating
 - E. Tremor of arms
847. The sleepiness is a clinical manifestation of the patient with:
- A. *Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
848. The general weakness is a clinical manifestation of the patient with:
- A. *Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
849. The malaise is a clinical manifestation of the patient with:
- A. *Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
850. The hypomnesia is a clinical manifestation of the patient with:

- A. *Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
851. The dry skin is a clinical manifestation of the patient with:
- A. *Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
852. The edemas is a clinical manifestation of the patient with:
- A. *Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
853. The constipation is a clinical manifestation of the patient with:
- A. *Hypothyroid goiter
 - B. Euthyroid goiter
 - C. Thyrotoxicosis
 - D. Gastric ulcer
 - E. Esophageal diverticulum
854. In case of hyperthyroid goiter the patient mainly complains of:
- A. *Excessive sweating
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
855. In case of hyperthyroid goiter the patient mainly complains of:
- A. *Irritability
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
856. In case of hyperthyroid goiter the patient mainly complains of:
- A. *Heartbeat
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
857. In case of hyperthyroid goiter the patient mainly complains of:
- A. *Tremor of arms
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
858. In case of hyperthyroid goiter the patient mainly complains of:
- A. *Sleeplessness
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
859. In case of hyperthyroid goiter the patient mainly complains of:

- A. *Feeling of fever
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
860. In case of hyperthyroid goiter the patient mainly complains of:
- A. *Loss of weight
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
861. The irritability is a clinical manifestation of the patient with:
- A. *Hyperthyroid goiter
 - B. Hypothyroid goiter
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
862. The heartbeat is a clinical manifestation of the patient with:
- A. *Hyperthyroid goiter
 - B. Hypothyroid goiter
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
863. The excessive sweating is a clinical manifestation of the patient with:
- A. *Hyperthyroid goiter
 - B. Hypothyroid goiter
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
864. The tremor of arms is a clinical manifestation of the patient with:
- A. *Hyperthyroid goiter
 - B. Hypothyroid goiter
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
865. The feeling of fever is a clinical manifestation of the patient with:
- A. *Hyperthyroid goiter
 - B. Hypothyroid goiter
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
866. The loss of weight is a clinical manifestation of the patient with:
- A. *Hyperthyroid goiter
 - B. Hypothyroid goiter
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
867. What is the main treatment of noncomplicated goiter?
- A. *Conservative treatment
 - B. Segmentectomy
 - C. Lobectomy
 - D. Thyroidectomy
 - E. Hemithyroidectomy
868. What medicines are used for the treatment of goiter?

- A. *Inorganic iodine
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
869. What medicines are used for the treatment of goiter?
- A. *Thyroidine
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
870. What medicines are used for the treatment of goiter?
- A. *Thyroxine
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
871. What medicines are used for the treatment of goiter?
- A. *Triiodothyronine
 - B. Heparin
 - C. Vasaprostan
 - D. Fenillin
 - E. Omeprasol
872. What is the indication for the operative treatment of the goiter?
- A. *Nodular goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
873. What is the indication for the operative treatment of the goiter?
- A. *Mixed forms of goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
874. What is the indication for the operative treatment of the goiter?
- A. *The sings of neck compression by goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
875. What is the indication for the operative treatment of the goiter?
- A. *The goiter with secondary hyperthyroidism
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
876. What is the indication for the operative treatment of the goiter?
- A. *The goiter with suspicion on malignancy
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
877. What is the indication for the operative treatment of the goiter?

- A. *The goiter of additional thyroid glands
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
878. What is the indication for the operative treatment of the goiter?
- A. *The aberrant goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
879. What is the indication for the operative treatment of the goiter?
- A. *The intrathoracic goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
880. What is the indication for the operative treatment of the goiter?
- A. *The retrosternal ectopy of thyroid gland
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
881. What is the indication for the operative treatment of the goiter?
- A. *The complicated goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Uncomplicated hypothyroid goiter
882. What is the indication for the conservative treatment of the goiter?
- A. *The goiter of I degree
 - B. The retrosternal ectopy of thyroid gland
 - C. The aberrant goiter
 - D. The goiter of IV degree
 - E. The goiter with secondary hyperthyroidism
883. What is the indication for the conservative treatment of the goiter?
- A. *The goiter of II degree
 - B. The retrosternal ectopy of thyroid gland
 - C. The aberrant goiter
 - D. The goiter of IV degree
 - E. The goiter with secondary hyperthyroidism
884. What operation is performed in endemic goiter?
- A. *Subfascial resection of thyroid gland
 - B. Segmentectomy
 - C. Lobectomy
 - D. Thyroidectomy
 - E. Hemithyroidectomy
885. Diffuse goiter with hyperthyroidism is called:
- A. *Grave's disease
 - B. Hashimoto disease
 - C. De Kerven disease
 - D. Riedel's disease
 - E. Raynaud's disease
886. Diffuse goiter with hyperthyroidism is called:

- A. *Basedow's disease
 - B. Hashimoto disease
 - C. De Kerven disease
 - D. Riedel's disease
 - E. Raynaud's disease
887. Basedow's disease is:
- A. *Thyrotoxicosis
 - B. Wooden thyroiditis
 - C. Purulent thyroiditis
 - D. Autoimmune thyroiditis
 - E. Mixedema
888. Grave's disease is:
- A. *Thyrotoxicosis
 - B. Wooden thyroiditis
 - C. Purulent thyroiditis
 - D. Autoimmune thyroiditis
 - E. Mixedema
889. What is the cause of thyrotoxicosis?
- A. *Autoimmune disturbances
 - B. Atherosclerotic changes
 - C. Calcium metabolism disturbances
 - D. Renal insufficiency
 - E. Pulmonary emphysema
890. What belongs to the I stage of thyrotoxicosis?
- A. *Onset of thyrotoxicosis, slight enlargement of thyroid gland
 - B. Marked sings of thyrotoxicosis, the thyroid is noticeably enlarged in size
 - C. Thyrotoxic lesion of viscera
 - D. Nonreversible dystrophy of organs and systems
 - E. Asymptomatic course
891. What belongs to the II stage of thyrotoxicosis?
- A. *Marked sings of thyrotoxicosis, the thyroid is noticeably enlarged in size
 - B. Onset of thyrotoxicosis, slight enlargement of thyroid gland
 - C. Thyrotoxic lesion of viscera
 - D. Nonreversible dystrophy of organs and systems
 - E. Asymptomatic course
892. What belongs to the III stage of thyrotoxicosis?
- A. *Thyrotoxic lesion of viscera
 - B. Marked sings of thyrotoxicosis, the thyroid is noticeably enlarged in size
 - C. Onset of thyrotoxicosis, slight enlargement of thyroid gland
 - D. Nonreversible dystrophy of organs and systems
 - E. Asymptomatic course
893. What belongs to the IV stage of thyrotoxicosis?
- A. *Nonreversible dystrophy of organs and systems
 - B. Thyrotoxic lesion of viscera
 - C. Marked sings of thyrotoxicosis, the thyroid is noticeably enlarged in size
 - D. Onset of thyrotoxicosis, slight enlargement of thyroid gland
 - E. Asymptomatic course
894. What stage of thyrotoxicosis correlates with the onset of the disease, slight enlargement of thyroid gland?
- A. *I
 - B. II
 - C. III
 - D. IV
 - E. 0

895. What stage of thyrotoxicosis correlates with the marked signs of thyrotoxicosis and noticeably enlarged thyroid?
- A. *II
 - B. I
 - C. III
 - D. IV
 - E. 0
896. What stage of thyrotoxicosis correlates with the thyrotoxic lesion of viscera?
- A. *III
 - B. II
 - C. I
 - D. IV
 - E. 0
897. What stage of thyrotoxicosis correlates with the nonreversible dystrophy of organs and systems?
- A. *IV
 - B. III
 - C. II
 - D. I
 - E. 0
898. What is the I stage of thyrotoxicosis?
- A. *Neurotic
 - B. Neurohormonal
 - C. Visceropathic
 - D. Cachectic
 - E. Asymptomatic
899. What is the II stage of thyrotoxicosis?
- A. *Neurohormonal
 - B. Neurotic
 - C. Visceropathic
 - D. Cachectic
 - E. Asymptomatic
900. What is the III stage of thyrotoxicosis?
- A. *Visceropathic
 - B. Neurohormonal
 - C. Neurotic
 - D. Cachectic
 - E. Asymptomatic
901. What is the IV stage of thyrotoxicosis?
- A. *Cachectic
 - B. Visceropathic
 - C. Neurohormonal
 - D. Neurotic
 - E. Asymptomatic
902. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. *Excessive sweating
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
903. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. *Irritability
 - B. Leg edemas
 - C. Hypomnesia

- D. Neck deformity
 - E. Constipation
904. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. *Heartbeat
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
905. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. *Tremor of arms
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
906. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. *Sleeplessness
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
907. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. *Feeling of fever
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
908. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. *Loss of weight
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
909. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. *Palpitation
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
910. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. *Exophthalmos
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
911. In case of thyrotoxicosis goiter the patient mainly complains of:
- A. *Tremor
 - B. Leg edemas
 - C. Hypomnesia
 - D. Neck deformity
 - E. Constipation
912. The palpitation is a clinical manifestation of the patient with:
- A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter

- D. Gastric ulcer
- E. Esophageal diverticulum
- 913. The palpitation is a clinical manifestation of the patient with:
 - A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
- 914. The exophthalmos is a clinical manifestation of the patient with:
 - A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
- 915. The tremor is a clinical manifestation of the patient with:
 - A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
- 916. The heartbeat is a clinical manifestation of the patient with:
 - A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
- 917. The excessive sweating is a clinical manifestation of the patient with:
 - A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
- 918. The tremor of arms is a clinical manifestation of the patient with:
 - A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
- 919. The feeling of fever is a clinical manifestation of the patient with:
 - A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
- 920. The loss of weight is a clinical manifestation of the patient with:
 - A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
- 921. For the laboratory disturbances of Basedow's disease is typical:
 - A. *Increased level of triiodothyronine
 - B. Decreased level of triiodothyronine
 - C. Increased level of glucocorticoids

- D. Decreased level of glucocorticoids
 - E. Decreased level of insulin
922. For the laboratory disturbances of Basedow's disease is typical:
- A. *Increased level of thyroxine
 - B. Decreased level of triiodothyronine
 - C. Increased level of glucocorticoids
 - D. Decreased level of glucocorticoids
 - E. Decreased level of insulin
923. For the laboratory disturbances of thyrotoxicosis is typical:
- A. *Increased level of protein metabolism
 - B. Decreased level of carbohydrate metabolism
 - C. Decreased level of lipid metabolism
 - D. Decreased level of protein metabolism
 - E. Decreased level of all kinds of metabolism
924. For the laboratory disturbances of thyrotoxicosis is typical:
- A. *Increased level of carbohydrate metabolism
 - B. Decreased level of carbohydrate metabolism
 - C. Decreased level of lipid metabolism
 - D. Decreased level of protein metabolism
 - E. Decreased level of all kinds of metabolism
925. For the laboratory disturbances of thyrotoxicosis is typical:
- A. *Increased level of lipid metabolism
 - B. Decreased level of carbohydrate metabolism
 - C. Decreased level of lipid metabolism
 - D. Decreased level of protein metabolism
 - E. Decreased level of all kinds of metabolism
926. The increased level of protein metabolism is typical for:
- A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
927. The increased level of lipid metabolism is typical for:
- A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
928. The increased level of carbohydrate metabolism is typical for:
- A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
929. The Graefe's sign is typical for:
- A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
930. The Stellwag's sign is typical for:
- A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter

- D. Gastric ulcer
- E. Esophageal diverticulum
- 931. The Mebius' sign is typical for:
 - A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
- 932. The Dalrymple's sign is typical for:
 - A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
- 933. The Kocher's sign is typical for:
 - A. *Thyrotoxicosis
 - B. Mixedema
 - C. Euthyroid goiter
 - D. Gastric ulcer
 - E. Esophageal diverticulum
- 934. The Graefe's sign is:
 - A. *The upper lid lag when the patient looks downward
 - B. Infrequent winking
 - C. A weakness of convergence
 - D. Wide palpebral fissure
 - E. Retraction of the upper eyelid at prompt change of view
- 935. The Mebius' sign is:
 - A. *A weakness of convergence
 - B. Infrequent winking
 - C. The upper lid lag when the patient looks downward
 - D. Wide palpebral fissure
 - E. Retraction of the upper eyelid at prompt change of view
- 936. The Stellwag's sign is:
 - A. *Infrequent winking
 - B. The upper lid lag when the patient looks downward
 - C. A weakness of convergence
 - D. Wide palpebral fissure
 - E. Retraction of the upper eyelid at prompt change of view
- 937. The Dalrymple's sign is:
 - A. *Wide palpebral fissure
 - B. Infrequent winking
 - C. The upper lid lag when the patient looks downward
 - D. A weakness of convergence
 - E. Retraction of the upper eyelid at prompt change of view
- 938. The Kocher's sign is:
 - A. *Retraction of the upper eyelid at prompt change of view
 - B. Wide palpebral fissure
 - C. Infrequent winking
 - D. The upper lid lag when the patient looks downward
 - E. A weakness of convergence
- 939. How is the sign, which is characterized by the upper lid lag when the patient looks downward named by author?
 - A. *Graefe's sign
 - B. Mebius' sign

- C. Stellwag's sign
 - D. Dalrymple's sign
 - E. Kocher's sign
940. How is the sign, which is characterized by infrequent winking named by author?
- A. *Stellwag's sign
 - B. Graefe's sign
 - C. Mebius' sign
 - D. Dalrymple's sign
 - E. Kocher's sign
941. How is the sign, which is characterized by a weakness of convergence named by author?
- A. *Mebius' sign
 - B. Stellwag's sign
 - C. Graefe's sign
 - D. Dalrymple's sign
 - E. Kocher's sign
942. How is the sign, which is characterized by a wide palpebral fissure named by author?
- A. *Dalrymple's sign
 - B. Mebius' sign
 - C. Stellwag's sign
 - D. Graefe's sign
 - E. Kocher's sign
943. How is the sign, which is characterized by retraction of the upper eyelid at prompt change of view named by author?
- A. *Kocher's sign
 - B. Dalrymple's sign
 - C. Mebius' sign
 - D. Stellwag's sign
 - E. Graefe's sign
944. For the thyrotoxicosis is typical:
- A. *Graefe's sign
 - B. Homan's sign
 - C. Lovenberg's sign
 - D. Mondor's sign
 - E. Murphy's sign
945. For the thyrotoxicosis is typical:
- A. *Mebius' sign
 - B. Homan's sign
 - C. Lovenberg's sign
 - D. Mondor's sign
 - E. Murphy's sign
946. For thyrotoxicosis is typical:
- A. *Stellwag's sign
 - B. Homan's sign
 - C. Lovenberg's sign
 - D. Mondor's sign
 - E. Murphy's sign
947. For the thyrotoxicosis is typical:
- A. *Dalrymple's sign
 - B. Homan's sign
 - C. Lovenberg's sign
 - D. Mondor's sign
 - E. Murphy's sign
948. For the thyrotoxicosis is typical:
- A. *Kocher's sign

- B. Homan's sign
 - C. Lovenberg's sign
 - D. Mondor's sign
 - E. Murphy's sign
949. What form of thyrotoxicosis is classified as a mild?
- A. *Pulse rate less than 100 beat/min
 - B. Pulse rate 100-120 beat/min
 - C. Pulse rate 120-140 beat/min
 - D. Pulse rate 140-160 beat/min
 - E. Pulse rate more than 160 beat/min
950. What form of thyrotoxicosis is classified as a moderate?
- A. *Pulse rate 100-120 beat/min
 - B. Pulse rate less than 100 beat/min
 - C. Pulse rate 120-140 beat/min
 - D. Pulse rate 140-160 beat/min
 - E. Pulse rate more than 160 beat/min
951. What form of thyrotoxicosis is classified as severe?
- A. *Pulse rate more than 120 beat/min
 - B. Pulse rate less than 40 beat/min
 - C. Pulse rate 40-80 beat/min
 - D. Pulse rate 80-100 beat/min
 - E. Pulse rate 100-120 beat/min
952. What form of thyrotoxicosis is classified as a mild?
- A. *Loss weight less than 3-5 kg
 - B. Loss weight 5-8 kg
 - C. Loss weight 8-10 kg
 - D. Loss weight 10-15 kg
 - E. Loss weight exceeds 15 kg
953. What form of thyrotoxicosis is classified as a moderate?
- A. *Loss weight 5-10 kg
 - B. Exceed of weight more than 1-2 kg
 - C. Exceed of weight more than 3-5 kg
 - D. Loss weight 10-15 kg
 - E. Loss weight exceeds 15 kg
954. What form of thyrotoxicosis is classified as severe?
- A. *Loss weight exceeds 10 kg
 - B. Loss weight less than 1-2 kg
 - C. Loss weight 2-3 kg
 - D. Exceed of weight more than 1-2 kg
 - E. Exceed of weight more than 3-5 kg
955. What form of thyrotoxicosis is classified as a mild?
- A. *Increase of basal metabolism to 30 %
 - B. Increase of basal metabolism on 30-50 %
 - C. Increase of basal metabolism more than 50 %
 - D. Decrease of basal metabolism to 30 %
 - E. Decrease of basal metabolism more than 50 %
956. What form of thyrotoxicosis is classified as a moderate?
- A. *Increase of basal metabolism on 30-50 %
 - B. Increase of basal metabolism to 30 %
 - C. Increase of basal metabolism more than 50 %
 - D. Decrease of basal metabolism to 30 %
 - E. Decrease of basal metabolism more than 50 %
957. What form of thyrotoxicosis is classified as severe?
- A. *Increase of basal metabolism more than 50 %

- B. Increase of basal metabolism on 30-50 %
 - C. Increase of basal metabolism to 30 %
 - D. Decrease of basal metabolism to 30 %
 - E. Decrease of basal metabolism more than 50 %
958. What form of thyrotoxicosis is related with the increase of basal metabolism on 30-50 %?
- A. *Moderate
 - B. Mild
 - C. Severe
 - D. Subclinic
 - E. Asymptomatic
959. What form of thyrotoxicosis is related with the increase of basal metabolism to 30 %?
- A. *Mild
 - B. Moderate
 - C. Severe
 - D. Subclinic
 - E. Asymptomatic
960. What form of thyrotoxicosis is related with the increase of basal metabolism more than 50 %?
- A. *Severe
 - B. Mild
 - C. Moderate
 - D. Subclinic
 - E. Asymptomatic
961. What form of thyrotoxicosis is related with the loss weight less than 3-5 kg?
- A. *Mild
 - B. Moderate
 - C. Severe
 - D. Subclinic
 - E. Asymptomatic
962. What form of thyrotoxicosis is related with the loss weight 5-10 kg?
- A. *Moderate
 - B. Mild
 - C. Severe
 - D. Subclinic
 - E. Asymptomatic
963. What form of thyrotoxicosis is related with the loss weight more than 10 kg?
- A. *Severe
 - B. Moderate
 - C. Mild
 - D. Subclinic
 - E. Asymptomatic
964. What is the most informative in the diagnostic of thyrotoxicosis?
- A. *Thyroid hormone concentration
 - B. General blood analysis
 - C. X-ray examination with barium
 - D. Coagulogram
 - E. X-ray examination of the neck
965. What is the most informative in the diagnostic of thyrotoxicosis?
- A. *Serum iodine-binding globulin concentration
 - B. General blood analysis
 - C. X-ray examination with barium
 - D. Coagulogram
 - E. X-ray examination of the neck
966. What is the most informative in the diagnostic of thyrotoxicosis?

- A. *Serum thyroidstimulating hormone of hypophysis
 - B. General blood analysis
 - C. X-ray examination with barium
 - D. Coagulogram
 - E. X-ray examination of the neck
967. What is the most informative in the diagnostic of thyrotoxicosis?
- A. *Serum thyroidstimulating antibodies
 - B. General blood analysis
 - C. X-ray examination with barium
 - D. Coagulogram
 - E. X-ray examination of the neck
968. What is the most informative in the diagnostic of thyrotoxicosis?
- A. *Detecting of basal metabolism
 - B. General blood analysis
 - C. X-ray examination with barium
 - D. Coagulogram
 - E. X-ray examination of the neck
969. What diseases should be the thyrotoxicosis differentiated with?
- A. *Rheumatic disease
 - B. Obesity
 - C. Lerishe's syndrome
 - D. Paget-Shretter's syndrome
 - E. Achalasia
970. What diseases should be the thyrotoxicosis differentiated with?
- A. *Chroniosepsis
 - B. Obesity
 - C. Lerishe's syndrome
 - D. Paget-Shretter's syndrome
 - E. Achalasia
971. What diseases should be the thyrotoxicosis differentiated with?
- A. *Diencephalic lesions
 - B. Obesity
 - C. Lerishe's syndrome
 - D. Paget-Shretter's syndrome
 - E. Achalasia
972. What diseases should be the thyrotoxicosis differentiated with?
- A. *Thyroid cancer
 - B. Obesity
 - C. Lerishe's syndrome
 - D. Paget-Shretter's syndrome
 - E. Achalasia
973. What diseases should be the thyrotoxicosis differentiated with?
- A. *Encephalitis
 - B. Obesity
 - C. Lerishe's syndrome
 - D. Paget-Shretter's syndrome
 - E. Achalasia
974. What medicines belong to thyrostatic agents?
- A. *Mercasolil
 - B. Euphyllin
 - C. Vasaprostan
 - D. Nicotine acid
 - E. Detrlex
975. What medicines belong to thyrostatic agents?

- A. *Lithium carbonate
 - B. Euphyllin
 - C. Vasaprostan
 - D. Nicotine acid
 - E. Detrlex
976. What group of medicines does Mercasolil belong to?
- A. *Thyrostatic agents
 - B. Antibiotics
 - C. Anticoagulants
 - D. Antiaggregants
 - E. Vitamines
977. What group of medicines does Lithium carbonate belong to?
- A. *Thyrostatic agents
 - B. Antibiotics
 - C. Anticoagulants
 - D. Antiaggregants
 - E. Vitamines
978. The subtotal subfascial resection of the thyroid gland is indicated for:
- A. *Thyrotoxicosis
 - B. Obesity
 - C. Lerishe's syndrome
 - D. Paget-Shretter's syndrome
 - E. Achalasia
979. The subtotal subfascial resection of the thyroid gland is indicated for:
- A. *Severe forms of thyrotoxicosis
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Goiter with hypothyroidism
980. The subtotal subfascial resection of the thyroid gland is indicated for:
- A. *Goiter of IV-V degree
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Goiter with hypothyroidism
981. The subtotal subfascial resection of the thyroid gland is indicated for:
- A. *Nodular transformation of toxic goiter
 - B. The goiter of 0 degree
 - C. The goiter of I degree
 - D. The goiter of II degree
 - E. Goiter with hypothyroidism
982. Among the typical complication of a postoperative period for thyrotoxicosis is:
- A. *Thyroid storm
 - B. Cretinism
 - C. Lerishe's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
983. Among the typical complication of a postoperative period for thyrotoxicosis is:
- A. *The damage of laryngeal nerve
 - B. Cretinism
 - C. Lerishe's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
984. Among the typical complication of a postoperative period for thyrotoxicosis is:

- A. *Asphyxia
 - B. Cretinism
 - C. Leriche's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
985. Among the complication of a postoperative period for thyrotoxicosis is:
- A. *Air embolism
 - B. Cretinism
 - C. Leriche's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
986. Among the typical complication of a postoperative period for thyrotoxicosis is:
- A. *Parathyroid tetany
 - B. Cretinism
 - C. Leriche's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
987. Among the typical complication of a postoperative period for thyrotoxicosis is:
- A. *Bleeding
 - B. Cretinism
 - C. Leriche's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
988. The development of excitement, up to psychosis and coma in early postoperative period after thyroid surgery is the manifestation of:
- A. *Thyroid storm
 - B. The damage of laryngeal nerve
 - C. Air embolism
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
989. The development of tachycardia (pulse rate – 150-200 per minute) in early postoperative period after thyroid surgery is the manifestation of:
- A. *Thyroid storm
 - B. The damage of laryngeal nerve
 - C. Parathyroid tetany
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
990. The development of complete arrhythmia in early postoperative period after thyroid surgery is the manifestation of:
- A. *Thyroid storm
 - B. The damage of laryngeal nerve
 - C. Leriche's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
991. The development of fever to 40°C in early postoperative period after thyroid surgery is the manifestation of:
- A. *Thyroid storm
 - B. The damage of laryngeal nerve
 - C. Leriche's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
992. The development of hyperemia of the face, neck, limbs in early postoperative period after thyroid surgery is the manifestation of:
- A. *Thyroid storm

- B. The damage of laryngeal nerve
 - C. Leriche's syndrome
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
993. The development of extremely sweating, diarrhea in early postoperative period after thyroid surgery is the manifestation of:
- A. *Thyroid storm
 - B. The damage of laryngeal nerve
 - C. Parathyroid tetany
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
994. The development of hoarseness in early postoperative period after thyroid surgery is the manifestation of:
- A. *The damage of laryngeal nerve
 - B. Thyroid storm
 - C. Parathyroid tetany
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
995. The development of aphonia in early postoperative period after thyroid surgery is the manifestation of:
- A. *The damage of laryngeal nerve
 - B. Thyroid storm
 - C. Parathyroid tetany
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
996. The development of cramps in early postoperative period after thyroid surgery is the manifestation of:
- A. *Parathyroid tetany
 - B. The damage of laryngeal nerve
 - C. Thyroid storm
 - D. Adrenal insufficiency
 - E. Itsenko-Cushing syndrome
997. For the clinical manifestation of thyroid storm is typical:
- A. *Excitement, up to psychosis and coma
 - B. Hoarseness
 - C. Cramps
 - D. Aphonia
 - E. Anemia
998. For the clinical manifestation of thyroid storm is typical:
- A. *Tachycardia (pulse rate – 150-200 per minute)
 - B. Hoarseness
 - C. Cramps
 - D. Aphonia
 - E. Anemia
999. For the clinical manifestation of thyroid storm is typical:
- A. *Complete arrhythmia
 - B. Hoarseness
 - C. Cramps
 - D. Aphonia
 - E. Anemia
1000. For the clinical manifestation of thyroid storm is typical:
- A. *Fever to 40°C
 - B. Hoarseness
 - C. Cramps

- D. Aphonia
 - E. Anemia
1001. For the clinical manifestation of thyroid storm is typical:
- A. *Hyperemia of the face, neck, limbs
 - B. Hoarseness
 - C. Cramps
 - D. Aphonia
 - E. Anemia
1002. For the clinical manifestation of thyroid storm is typical:
- A. *Extremely sweating
 - B. Hoarseness
 - C. Cramps
 - D. Aphonia
 - E. Anemia
1003. For the clinical manifestation of thyroid storm is typical:
- A. *Diarrhea
 - B. Hoarseness
 - C. Cramps
 - D. Aphonia
 - E. Anemia
1004. For the clinical manifestation of the damage of laryngeal nerve is typical:
- A. *Hoarseness
 - B. Diarrhea
 - C. Cramps
 - D. Fever to 40°C
 - E. Anemia
1005. For the clinical manifestation of the damage of laryngeal nerve is typical:
- A. *Aphonia
 - B. Diarrhea
 - C. Cramps
 - D. Fever to 40°C
 - E. Anemia
1006. For the clinical manifestation of the parathyroid tetany is typical:
- A. *Cramps
 - B. Aphonia
 - C. Diarrhea
 - D. Fever to 40°C
 - E. Anemia
1007. The purulent thyroiditis is a:
- A. *De Kerven thyroiditis
 - B. Hashimoto's goiter
 - C. Riedel's goiter
 - D. Grave's disease
 - E. Basedow's disease
1008. The autoimmune thyroiditis is a:
- A. *Hashimoto's goiter
 - B. De Kerven thyroiditis
 - C. Riedel's goiter
 - D. Grave's disease
 - E. Basedow's disease
1009. The fibrous thyroiditis is a:
- A. *Riedel's goiter
 - B. Hashimoto's goiter
 - C. De Kerven thyroiditis

- D. Grave's disease
- E. Basedow's disease
- 1010. The "woody" goiter is a:
 - A. *Riedel's goiter
 - B. Hashimoto's goiter
 - C. De Kerven thyroiditis
 - D. Grave's disease
 - E. Basedow's disease
- 1011. The Riedel's goiter is a:
 - A. *"Woody" goiter
 - B. Autoimmune thyroiditis
 - C. Purulent thyroiditis
 - D. Thyrotoxicosis
 - E. Nodular goiter
- 1012. The Riedel's goiter is a:
 - A. *Fibrous thyroiditis
 - B. Autoimmune thyroiditis
 - C. Purulent thyroiditis
 - D. Thyrotoxicosis
 - E. Nodular goiter
- 1013. The Hashimoto's goiter is a:
 - A. *Autoimmune thyroiditis
 - B. Fibrous thyroiditis
 - C. Purulent thyroiditis
 - D. Thyrotoxicosis
 - E. Nodular goiter
- 1014. The De Kerven thyroiditis is a:
 - A. *Purulent thyroiditis
 - B. Autoimmune thyroiditis
 - C. Fibrous thyroiditis
 - D. Thyrotoxicosis
 - E. Nodular goiter
- 1015. The treatment of de Kerven thyroiditis is a:
 - A. *Drainage of suppurative focus
 - B. Glycocorticoids
 - C. Radioactive iodine
 - D. Resection of thyroid gland
 - E. Mercasolil
- 1016. The treatment of Hashimoto's goiter is a:
 - A. *Glycocorticoids
 - B. Drainage of suppurative focus
 - C. Radioactive iodine
 - D. Resection of thyroid gland
 - E. Mercasolil
- 1017. The treatment of Hashimoto's goiter is a:
 - A. *Thyroidectomy
 - B. Drainage of suppurative focus
 - C. Radioactive iodine
 - D. Resection of thyroid gland
 - E. Mercasolil
- 1018. The treatment of Riedel's goiter is a:
 - A. *Thyroidectomy
 - B. Drainage of suppurative focus
 - C. Radioactive iodine

- D. Resection of thyroid gland
 - E. Mercasolil
1019. What vessels are usually affected by atherosclerosis obliterans?
- A. *Aorta and arteries
 - B. Arterioles
 - C. Microcirculatory bed
 - D. Superficial veins
 - E. Deep veins
1020. What is the morphological basis of atherosclerotic lesions?
- A. *The accumulation of lipids in the intima
 - B. Thrombosis
 - C. Inflammatory process
 - D. Embolism
 - E. Aneurysm
1021. What is the main cause of atherosclerotic lesions?
- A. *Hypercholesterolemia, dyslipoproteinemia
 - B. Infection
 - C. Trauma
 - D. Rheumatism, endocarditis
 - E. Myocardial infarction
1022. What does apply to the first stage of atherosclerotic lesions according to the classification by Fontane?
- A. *Full compensation
 - B. Asymptomatic ran
 - C. Functional circulatory insufficiency
 - D. Limb ischemia at rest
 - E. Destruction of tissue
1023. What does belong to the second stage of atherosclerotic lesions according to the classification by Fontane?
- A. *Functional circulatory insufficiency
 - B. Asymptomatic ran
 - C. Full compensation
 - D. Limb ischemia at rest
 - E. Destruction of tissue
1024. What does belong to the third stage of atherosclerotic lesions according to the classification by Fontane?
- A. *Limb ischemia at rest
 - B. Asymptomatic ran
 - C. Full compensation
 - D. Functional circulatory insufficiency
 - E. Destruction of tissue
1025. What does belong to the fourth stage of atherosclerotic lesions according to the classification by Fontane?
- A. *Destruction of tissue
 - B. Asymptomatic ran
 - C. Full compensation
 - D. Functional circulatory insufficiency
 - E. Limb ischemia at rest
1026. What is the most typical feature of the first stage of atherosclerotic lesions?
- A. *Cooling of the lower extremities
 - B. Fever
 - C. Intermittent claudication
 - D. Gangrene
 - E. Pain at rest

1027. What is the most typical sign of the second stage of atherosclerotic lesions?
- A. *Intermittent claudication
 - B. Cooling of the lower extremities
 - C. Fever
 - D. Gangrene
 - E. Pain at rest
1028. What is the most typical feature of the third stage of atherosclerotic lesions?
- A. *Pain at rest
 - B. Fever
 - C. Cooling of the lower extremities
 - D. Intermittent claudication
 - E. Gangrene
1029. What is the most typical feature of the fourth stage of atherosclerotic lesions?
- A. *Gangrene
 - B. Pain at rest
 - C. Fever
 - D. Cooling of the lower extremities
 - E. Intermittent claudication
1030. What is characterized by intermittent claudication?
- A. *Pain in the muscles of his legs when walking, which disappears after rest
 - B. Ischialgia, lumbago
 - C. Constant pain in the joints
 - D. Pain along the superficial veins
 - E. Edema of lower extremities
1031. Intermittent claudication is characterized by:
- A. *Pain in the lower extremities
 - B. Heartache
 - C. Arthralgia
 - D. Dizziness
 - E. Edema of lower extremities
1032. Intermittent claudication is characterized for:
- A. *Atherosclerosis of the lower extremities
 - B. Deep vein thrombosis
 - C. Pancreatitis
 - D. Varicose
 - E. Cholecystitis
1033. To what stage of atherosclerotic lesions is characteristic intermittent claudication up to 1000 meters?
- A. *II
 - B. IIA
 - C. IIB
 - D. III
 - E. IV
1034. To what stage of atherosclerotic lesions is characteristic intermittent claudication before 500 meters?
- A. *IIA
 - B. I
 - C. III
 - D. IIB
 - E. IV
1035. To what stage of atherosclerotic lesions characteristic of intermittent claudication before 200 meters?
- A. *IIB
 - B. I

- C. IIA
 - D. IV
 - E. III
1036. To what stage of atherosclerotic lesions is characteristic of intermittent claudication 25-50 meters?
- A. *III
 - B. I
 - C. IIA
 - D. IV
 - E. IIB
1037. To what stage of atherosclerotic lesions is characteristic the pain at rest?
- A. *III
 - B. I
 - C. IIA
 - D. IV
 - E. IIB
1038. To what stage of atherosclerotic lesions characteristic dry trophic ulcer?
- A. *III
 - B. I
 - C. IIA
 - D. IV
 - E. IIB
1039. To what stage of atherosclerotic lesions is characteristic the necrosis and gangrene?
- A. *IV
 - B. III
 - C. I
 - D. IIA
 - E. II B
1040. What is the main cause of limb swelling in patients with atherosclerosis obliterans?
- A. *Permanent seating position to relieve pain
 - B. Deep vein thrombosis
 - C. Infection, abscess
 - D. Arterial thrombosis
 - E. Heart failure
1041. Where is the most frequent location of venous ulcers with obliterating atherosclerosis?
- A. *At the tip of the toes
 - B. In the lower third of the lower extremities
 - C. In the upper third of the lower extremities
 - D. On the back of the knee
 - E. At the hip
1042. Leriche syndrome is:
- A. *Occlusion the bifurcation of abdominal aorta
 - B. Stenosis the brachiocephalic trunk
 - C. Renal artery stenosis
 - D. Stenosis of the abdominal trunk
 - E. Stenosis of pulmonary artery
1043. Leriche syndrome is characterized by:
- A. *Atherosclerotic lesions
 - B. Obliterative endarteritis
 - C. Varicose
 - D. Phlebemphraxis
 - E. Lymphedema
1044. Leriche is characterized by:
- A. *Atherosclerotic lesions

- B. Acute cholecystitis
 - C. Acute pancreatitis
 - D. Ileus
 - E. Appendicular infiltrate
1045. For Leriche syndrome is characterized by:
- A. *Intermittent claudication
 - B. Angina
 - C. Dizziness
 - D. Oedema of lower extremities
 - E. Extension of saphenous veins
1046. For Leriche syndrome is characterized by:
- A. *The absence of pulsations in the lower extremities
 - B. Hyperbilirubinemia
 - C. Ascites
 - D. Oedema of lower extremities
 - E. Extension of saphenous veins
1047. For Leriche syndrome is characterized by:
- A. *Hypercholesterolemia
 - B. Hyperbilirubinemia
 - C. Increased blood amylase
 - D. Leukocytosis
 - E. Anemia
1048. For Leriche syndrome is characteristic X-ray symptoms:
- A. *Occlusion of the terminal aorta
 - B. Occlusion of terminal part of the inferior vena cava
 - C. Occlusion of the superior vena cava
 - D. Dysplasia arteries
 - E. Dysplasia veins
1049. For Leriche syndrome is characteristic X-ray symptoms:
- A. *Occlusion of the terminal aorta
 - B. Cloiber's bowls
 - C. Pneumoperitoneum
 - D. The symptom of "niche"
 - E. Detelectasis
1050. At Leriche syndrome patient has complains on:
- A. *Intermittent claudication
 - B. Pain in the heart
 - C. Oedema of lower extremities
 - D. Extension of saphenous veins
 - E. Dizziness
1051. At Leriche syndrome patient has complains on:
- A. *Melosalgia
 - B. Pain in the heart
 - C. Pain during urination
 - D. Tenesmus
 - E. Pain in the epigastric area
1052. At what level is absent arterial pulsation at the Leriche syndrome?
- A. *Femoral artery
 - B. Posterior tibial artery
 - C. Dorsal artery of foot
 - D. Popliteal artery
 - E. Common carotid artery
1053. What complication is caused by atherosclerosis obliterans?
- A. *Acute arterial thrombosis

- B. Arteriorrhexis
 - C. Acute venous thrombosis
 - D. Phlegmon
 - E. Superficial thrombophlebitis
1054. What complication is caused by atherosclerosis obliterans?
- A. *Aneurysm
 - B. Arteriorrhexis
 - C. Acute venous thrombosis
 - D. Phlegmon
 - E. Superficial thrombophlebitis
1055. Which clinical sign is typical for abdominal aortic aneurysm?
- A. *Systolic noise over a pulsating formation in the abdominal cavity
 - B. Abdominal pain
 - C. Leukopenia
 - D. Diarrhea
 - E. Tension of abdominal wall
1056. Which clinical sign is typical for the rupture abdominal aortic aneurysm?
- A. *Hemorrhagic shock
 - B. Leukopenia
 - C. Systolic noise over a pulsating formation in the abdominal cavity
 - D. Diarrhea
 - E. Tension of abdominal wall
1057. Which clinical sign is typical bundle abdominal aortic aneurysm?
- A. *They expressed the pain radiating to the loin
 - B. Pukes bile
 - C. Systolic noise over the formation of a pulsating abdominal
 - D. Diarrhea
 - E. Voltage anterior abdominal wall
1058. What is the treatment of uncomplicated aortic aneurysm?
- A. *Aortic prosthesis
 - B. Saphenectomy
 - C. Conservative treatment
 - D. Ligation of the aorta
 - E. Profundoplastic
1059. What is the treatment gap abdominal aortic aneurysm?
- A. *Endovascular prostheses
 - B. Saphenectomy
 - C. Conservative treatment
 - D. Ligation of the aorta
 - E. Profundoplastic
1060. Which of the instrumental methods of investigation is the most informative at obliterating atherosclerosis?
- A. *Ultrasound
 - B. ECG
 - C. Spirography
 - D. Urography
 - E. Target biopsy
1061. In obliterating atherosclerosis determined by:
- A. *Lenel-Lavestin's symptom
 - B. Homan's symptom
 - C. Ortner's symptom
 - D. Rovzing's symptom
 - E. Babinski symptom
1062. The pulsation of the femoral artery is determined by:

- A. *By the middle of the inguinal ligament;
 - B. By the middle line above the stomach and the navel;
 - C. By the mid-popliteal fossa with slightly bent limbs in the knee;
 - D. Between the back-bottom edge of the medial bone and Achilles tendon;
 - E. Between I and II metatarsals.
1063. The pulsation of the abdominal aorta is determined by:
- A. *On the middle line above the stomach and the navel;
 - B. On the middle of the inguinal ligament;
 - C. On the middle popliteal fossa with slightly bent limbs in the knee;
 - D. Between lowback edge of the medial bone and Achilles tendon;
 - E. Between I and II metatarsals.
1064. The pulsation of the popliteal artery is defined:
- A. *On the middle popliteal fossa with slightly bent limbs in the knee;
 - B. On the middle line above the stomach and the navel;
 - C. On the middle of the inguinal ligament;
 - D. Between the back-bottom edge of the medial bone and Achilles tendon;
 - E. Between I and II metatarsals.
1065. The pulsation of the posterior tibial artery is determined by:
- A. *Between the back-bottom edge of the medial bone and Achilles tendon;
 - B. On the middle popliteal fossa with slightly bent limbs in the knee;
 - C. On the middle line above the stomach and the navel;
 - D. On the middle of the inguinal ligament;
 - E. Between I and II metatarsals.
1066. Ripple dorsal artery of foot is determined by:
- A. *Between I and II metatarsals.
 - B. Between lowback edge of the medial bone and Achilles tendon;
 - C. On the middle popliteal fossa with slightly bent limbs in the knee;
 - D. On the middle line above the stomach and the navel;
 - E. On the middle of the inguinal ligament;
1067. What kind of ankle pressure is characterize the critical ischemia?
- A. *Less than 50 mm Hg.
 - B. Less than 140 mm Hg.
 - C. Less than 70 mm Hg.
 - D. Less than 90 mm Hg.
 - E. Less than 110 mm Hg.
1068. What kind of ankle pressure is characterized the II stage of the chronic ischemia?
- A. *Less than 90 mm Hg.
 - B. Less than 50 mm Hg.
 - C. Less than 140 mm Hg.
 - D. Less than 70 mm Hg.
 - E. Less than 110 mm Hg.
1069. What kind of ankle index corresponds to II stage of the chronic ischemia?
- A. *Less than 0,9.
 - B. Less than 0,5.
 - C. 1,0.
 - D. More than 1,0.
 - E. More than 1,5.
1070. What kind of ankle index corresponds to III stage of the chronic ischemia?
- A. *Less than 0,5.
 - B. Less than 0,9.
 - C. 1,0.
 - D. More than 1,0.
 - E. More than 1,5.
1071. Which of the X-ray methods is the most informative at obliterating atherosclerosis?

- A. *Arteriography
 - B. Abdominal radiography
 - C. Chest radiography
 - D. Radiography limb
 - E. Phlebography
1072. For atherosclerotic lesions at arteriography is characterized by:
- A. *Segmental occlusion of the arteries
 - B. Occlusion of terminal part of the inferior vena cava
 - C. Occlusion of the superior vena cava
 - D. Dysplasia arteries
 - E. Diffuse stenosis of small arteries
1073. What is the main distinctive feature between atherosclerosis and endarteritis obliterans?
- A. *The level of arterial pulsation
 - B. Pain syndrome
 - C. Trophic ulcers
 - D. Changes in coagulation
 - E. Skin color
1074. What method of research is the most informative in the differential diagnosis between atherosclerosis and endarteritis obliterans?
- A. *Angiography
 - B. ECG
 - C. Biochemical analysis of blood
 - D. Complete blood
 - E. Target biopsy
1075. What is the main distinctive feature between atherosclerosis and lumbosacral radiculitis?
- A. *Arterial pulsation in the lower extremities
 - B. Pain syndrome of the lower extremities
 - C. The color of the skin of the lower extremities
 - D. Cold extremities
 - E. Paresthesias of lower extremities
1076. At what level is no ripple at lumbosacral radiculitis?
- A. *Stored at all levels of
 - B. Calf arteries
 - C. Popliteal artery
 - D. Femoral artery
 - E. Aorta
1077. Which method to study is the most informative in the differential diagnosis between atherosclerosis and diabetic angiopathy?
- A. *Biochemical analysis of blood
 - B. Complete blood
 - C. Koagulogramme
 - D. Immunogramma
 - E. Urinalysis
1078. Which clinical sign is not typical for diabetic angiopathy?
- A. *No pulsation of femoral artery
 - B. Necrosis of the fingers on the lower extremity
 - C. Trophic ulcers on the foot
 - D. Phlegmon of the foot
 - E. Paresthesias
1079. What are the indications for conservative therapy of obliterative atherosclerosis?
- A. *I-II stage of chronic arterial insufficiency
 - B. Not shown at all
 - C. III-IV stage of chronic arterial insufficiency
 - D. Leriche syndrome

- E. Arterial thrombosis
1080. Which drugs has affect on atherogenesis?
- A. *Cholestyramine
 - B. Trental
 - C. Vasaprostan
 - D. Nicotinic acid
 - E. Aspirin
1081. Which drug does belongs to antiaggregants?
- A. *Pentoksiphilin
 - B. Cholestyramine
 - C. Vasaprostan
 - D. Nicotinic acid
 - E. Papaverine
1082. What are the indications for surgical arterial reconstruction?
- A. *II-III stage of chronic arterial insufficiency
 - B. No evidence
 - C. I-II stage of chronic arterial insufficiency
 - D. Gangrene of the lower extremity
 - E. Phlegmon of the lower extremity
1083. Which operation is performed with Leriche syndrome?
- A. *Aorto-femoral bypass
 - B. Lumbar sympathectomy
 - C. Intimectomy
 - D. Resection of the arteries
 - E. Artery ligation
1084. Which operation is performed at Leriche syndrome?
- A. *Right answer is absent
 - B. Bypass thick intestinal anastomosis
 - C. Gastrectomy
 - D. Cholecystectomy
 - E. Saphenectomy
1085. What are the indications for endarterectomy:
- A. *Isolated segmental occlusion of the artery
 - B. Leriche syndrome
 - C. Multi-storey artery occlusion
 - D. Calcinosis artery
 - E. Occlusive disease
1086. What is the most common operation at atherosclerotic occlusion of the femoral artery?
- A. *Autogenous vein bypass
 - B. Lumbar sympathectomy
 - C. Intimectomy
 - D. Resection of the arteries
 - E. Artery ligation
1087. What is the localization of arterial occlusion requires prothundoplastic?
- A. *Bifurcation of the common femoral artery
 - B. Bifurcation of the aorta
 - C. Bifurcation of common iliac artery
 - D. Trifurcation popliteal artery
 - E. Bifurcation carotid artery
1088. What is the complication of arterial reconstruction does not require repeated surgical intervention?
- A. *Deep vein thrombosis
 - B. Arterial thrombosis
 - C. Arterial bleeding

- D. Injection of synthetic graft
 - E. The increase in lower limb ischemia
1089. What are indication to amputation at obliterating atherosclerosis?
- A. *Gangrene of the lower extremity
 - B. Leriche
 - C. I-II stage of ischemia
 - D. II-III stage of ischemia
 - E. Arterial bleeding
1090. Which artery are usually affects occlusive endarteritis?
- A. *Calf arteries
 - B. Aorta
 - C. Iliac arteries
 - D. Femoral artery
 - E. Deep femoral artery
1091. What factors play a very significant role in pathogenesis the obliterative endarteritis?
- A. *Chronic intoxication
 - B. Hyperlipidemia
 - C. Triglyceridemia
 - D. Vascular injury
 - E. Thrombophlebitis
1092. What is the morphological basis of obliterative endarteritis?
- A. *Intimal hyperplasia
 - B. Atheroma
 - C. Embolism
 - D. Aneurysm
 - E. Arteriovenous fistula
1093. What is the fourth stage of obliterating endarteritis?
- A. *Ulcer-necrotic
 - B. Asymptomatic
 - C. Coronary
 - D. Trophic changes
 - E. Gangrenous
1094. What is the main feature of obliterative endarteritis?
- A. *Intermittent claudication
 - B. Muscle contraction
 - C. Fever
 - D. Arthritic pain
 - E. Ishalgia
1095. What is the cause of intermittent claudication?
- A. *Muscle ischemia
 - B. Trauma
 - C. Ishalgia
 - D. Muscle contraction
 - E. Arthritic pain
1096. The most typical localization of intermittent claudication at occlusive disease is?
- A. *Foot
 - B. Stifle
 - C. Hip
 - D. Hip
 - E. Stomach
1097. Cooling stop is characteristic:
- A. *Surface thrombophlebitis
 - B. Deep thrombophlebitis
 - C. Obliterative endarteritis

- D. Lymphostasis
- E. Postthrombotic syndrome
- 1098. Blanching of the skin foot is characteristic:
 - A. *Obliterative endarteritis
 - B. Deep thrombophlebitis
 - C. Surface thrombophlebitis
 - D. Postthrombotic syndrome
 - E. Phlegmon of the foot
- 1099. What is the typical location the venous ulcers at occlusive disease?
 - A. *At fingertips
 - B. In the lower third of the lower extremities
 - C. In the upper third of the lower extremities
 - D. On the back of the knee
 - E. At the hip
- 1100. What is the typical sign for the I stage of obliterating endarteritis?
 - A. *Cooling of the lower extremities
 - B. Intermittent claudication
 - C. Fever
 - D. Pain at rest
 - E. Gangrene
- 1101. What is the typical sign for II stage the obliterative endarteritis?
 - A. *Intermittent claudication
 - B. Fever
 - C. Cooling of the lower extremities
 - D. Gangrene
 - E. Pain at rest
- 1102. What is the typical sign for the III stage of obliterating endarteritis?
 - A. *Pain at rest
 - B. Cooling of the lower extremities
 - C. Fever
 - D. Intermittent claudication
 - E. Gangrene
- 1103. What is the typical sign for the IV stage of obliterating endarteritis?
 - A. *Gangrene
 - B. Cooling of the lower extremities
 - C. Fever
 - D. Pain at rest
 - E. Intermittent claudication
- 1104. What is the most frequent complication the obliterative endarteritis?
 - A. *Arterial thrombosis and gangrene of the extremities
 - B. Bleeding
 - C. Blindness
 - D. Chylorrhea
 - E. Aneurysm
- 1105. What is the main goal of therapy at obliterating endarteritis?
 - A. *Renewal or improvement of capillary circulation
 - B. Resumption pass vein
 - C. Resumption of the entrance of lymph
 - D. Resumption pass arteries
 - E. Improving the innervation of the lower extremity
- 1106. For obliterative endarteritis is characterized by:
 - A. *Intermittent claudication
 - B. Angina
 - C. Dizziness

- D. Oedema of lower extremities
- E. Extension of saphenous veins
- 1107. For obliterative endarteritis is characterized by:
 - A. *The pulse absent on the feet
 - B. Hyperbilirubinemia
 - C. Ascites
 - D. Oedema of lower extremities
 - E. Extension of saphenous veins
- 1108. For obliterative endarteritis is characteristic X-ray symptoms:
 - A. *Diffuse stenosis of small arteries
 - B. Occlusion of terminal part of the inferior vena cava
 - C. Occlusion of the superior vena cava
 - D. Arteries dysplasia
 - E. Veins dysplasia
- 1109. For obliterative endarteritis is characteristic X-ray symptoms:
 - A. *No right answer
 - B. Bowls Kloiber
 - C. Pneumoperitoneum
 - D. The symptom of "niche"
 - E. Detelectasis
- 1110. At occlusive disease patient complains on:
 - A. *Intermittent claudication
 - B. Pain in the heart
 - C. Oedema of lower extremities
 - D. Extension of saphenous veins
 - E. Dizziness
- 1111. At obliterating endarteritis patient complains of:
 - A. *Melosalgia
 - B. Pain in the heart
 - C. Pain during urination
 - D. Tenesmus
 - E. Pain in the epigastric area
- 1112. At what level is absent arterial pulsation at obliterative endarteritis ?
 - A. *Arteries foot
 - B. Femoral artery
 - C. Popliteal artery
 - D. Common carotid artery
 - E. Abdominal aorta
- 1113. Which group of drugs are pentoxifyllinum?
 - A. *Antiagrigant
 - B. Antispasmodic
 - C. Antihistamines
 - D. Stimulants metabolism
 - E. Narcotic analgesics
- 1114. Which group of drugs are vasaprostan?
 - A. *Prostaglandins
 - B. Antiagrigant
 - C. Antispasmodic
 - D. Antihistamines
 - E. Stimulants metabolism
- 1115. Which operation is performed at obliterative endarteritis ?
 - A. *Lumbar sympathectomy
 - B. Intimectomy
 - C. Bypass grafting

- D. Resection of the arteries
 - E. Artery ligation
1116. Which factor is the leader in the development of atherosclerosis?
- A. *Dyslipoproteinemia.
 - B. Diabetes.
 - C. Suprarenalism.
 - D. Frequent hypothermia.
 - E. Smoking.
1117. Which factor is the leader in the development of obliterative endarteritis?
- A. *Hypothermia, intoxication.
 - B. Hypercholesterolemia.
 - C. Diabetes.
 - D. Violations electrolytic exchange.
 - E. Suprarenalism.
1118. At what age is the greatest risk of ill atherosclerosis obliterans?
- A. *Older than 40 years.
 - B. In 20 - 60 years.
 - C. In 19 - 25 years.
 - D. In 30 - 35 years.
 - E. In 35 - 39 years.
1119. At what age is the greatest risk of ill obliterative endarteritis?
- A. *Up to 40 years.
 - B. 41 - 50 years.
 - C. 51 - 60 years.
 - D. In 10 - 15 years.
 - E. Over 60 years.
1120. At atherosclerosis obliterans first affected:
- A. *Arteries, aorta.
 - B. Arteriovenous shunt vessels.
 - C. Capillaries.
 - D. Arteries of medium diameter.
 - E. Small arteries.
1121. At obliterative endarteritis first affected:
- A. *Peripheral arteries.
 - B. Inguinal artery.
 - C. Aorta.
 - D. Ventral trunk.
 - E. The upper and lower mesenteric artery.
1122. At what disease you can auscultated systolic murmur on the major arteries?
- A. *In obliterating atherosclerosis.
 - B. When occlusive disease.
 - C. With varicose veins.
 - D. In acute venous thrombosis shins.
 - E. When ileofemoralnom venous thrombosis.
1123. With the defeat of what artery atherosclerosis can develops Leriche syndrome?
- A. *Bifurcation of the aorta, common iliac arteries.
 - B. Popliteal artery.
 - C. Arteries of the lower leg.
 - D. Ventral trunk.
 - E. Inferior mesenteric artery.
1124. What kind of reconstructive operations on the vessels are carried out with Leriche syndrome?
- A. *Aorto-femoral prosthesis or bypass surgery.
 - B. Operation Linton or Kokkett.

- C. Leriche's operation.
 - D. Troyanov-Trendelenburg's operation, Babcock's operation.
 - E. Embolectomy
1125. What kind of reconstructive operations on the major arteries are carried out with obliterating atherosclerosis?
- A. *Endarterectomy, bypass surgery or prosthetic arteries.
 - B. Leriche's operation.
 - C. Lumbar sympathectomy.
 - D. Palm's operation .
 - E. Troyanov-Trendelenburg's operation.
1126. What operations are conducted in obliterating endarterite lower extremities?
- A. *Lumbar sympathectomy, Leriche's operation.
 - B. Embolectomy
 - C. Saphenectomy.
 - D. Thrombectomy.
 - E. Intimectomy
1127. What kind of manipulation to be done vascular prostheses infection?
- A. *Remove the prosthesis.
 - B. Catheterization subclavian vein.
 - C. Catheterization great saphenous vein.
 - D. Fasciotomy.
 - E. Necrectomy.
1128. Named the arteries that catheterization for aortography with bilateral Leriche syndrome?
- A. *Brachial artery.
 - B. Total n artery.
 - C. Thigh iliac artery.
 - D. Subclavian artery.
 - E. Rear leg artery
1129. Aorto-occlusive disease at arteriogram characterized by:
- A. *Uniform narrowing of the lumen of the arteries of the lower extremities.
 - B. Occlusion of peripheral arteries.
 - C. Uneven narrowing of the lumen of the arteries of the lower extremities.
 - D. Occlusion of collateral arteries.
 - E. Occlusion of capillaries.
1130. Lumbar sympathectomy is accompanied by:
- A. *Removing the spasm of precapillary sphincter .
 - B. Decrease in prothrombin index.
 - C. Normalization of glucose.
 - D. Increased protein content in blood serum.
 - E. Normalization of bilirubin in the blood serum.
1131. To improve the microcirculation provide drugs:
- A. *Nicotinic acid, reopolyglukine.
 - B. Diphenhydramine, suprastin.
 - C. Anaprilin, lineotol.
 - D. Cytitone, lobeline.
 - E. Amidopyrine, analgin.
1132. What drugs have antisclerotic action?
- A. *Clofibrate, linetol, parmidin.
 - B. Cytitone, lobeline.
 - C. Fenilin, Omefin.
 - D. Nicotinic acid.
 - E. Diphenhydramine, suprastin.
1133. What methods are used to reduce the concentration of cholesterol and lipoproteins in the blood serum?

- A. *Plasmapheresis, hemosorption.
 - B. Artificial diuresis.
 - C. Hemodilution.
 - D. Transfusion of blood
 - E. Introduction vasorostana
1134. At what level are removed ganglia at the lumbar sympathectomy?
- A. *L3 - L4.
 - B. S2 - S3.
 - C. L1.
 - D. Th 10-17
 - E. Th 8-9.
1135. How soon after the appointment of showing its effect indirect anticoagulants?
- A. *After 12 - 48 hours.
 - B. After 4 hours.
 - C. After 72 hours.
 - D. After 56 hours.
 - E. 46-56 hours.
1136. Specify non-pharmacological methods of correcting blood coagulation system.
- A. Hemodilution.
 - B. Hemodialysis.
 - C. Hemosorption.
 - D. Artificial diuresis.
 - E. Limfosorbtsiya.
1137. What are the contrast agents used for angiography?
- A. *Triyodtrast, verografín.
 - B. Methylene blue.
 - C. Barium sulfate.
 - D. Alprostan.
 - E. Vasoprostan.
1138. Catheterization of the aorta is performed by:
- A. *Seldinger.
 - B. Billroth.
 - C. Kocher
 - D. Pirogov
 - E. Shalimov
1139. What complications may arise during percutaneous catheterization of the aorta by Seldinger?
- A. *Bleeding, thrombosis, embolism.
 - B. Acute thrombophlebitis leg veins.
 - C. Relaxation of the diaphragm.
 - D. Thrombosis of the subclavian vein.
 - E. Endocarditis.
1140. At occlusion what arteries can develops Leriche syndrome:
- A. *Occlusion of the aortic bifurcation, common iliac arteries
 - B. Occlusion of inferior mesenteric artery
 - C. Occlusion of the subclavian and brachial arteries
 - D. Occlusion of the popliteal artery and lower leg
 - E. Occlusion of the internal iliac arteries
1141. At occlusion what arteries can develops unilateral Leriche syndrome?
- A. *Occlusion of the external and common iliac arteries
 - B. Occlusion of the internal iliac arteries
 - C. Occlusion of the aortic bifurcation
 - D. Occlusion of the deep femoral artery
 - E. Occlusion of popliteal artery

1142. For aorto-arteriography using contrast agents:
- A. *Triumbrast, verografin, urotrast
 - B. Seabar
 - C. Bilignost
 - D. Holevid
 - E. Iodognost
1143. Aorto-arteriography by percutaneous catheterization of the aorta through a peripheral artery is developed:
- A. *Seldingerom
 - B. Petrovsky
 - C. Suharev
 - D. Pokrovsky
 - E. Vishnevsky
1144. For aorto-arteriografii with bilateral Leriche syndrome conducted puncture:
- A. *Brachialis artery
 - B. Femoral artery
 - C. Popliteal artery
 - D. External iliac artery
 - E. Cubital vein
1145. At obliterating atherosclerosis affected:
- A. *Aorta and arteries
 - B. Small and small arteries
 - C. Arterivenoznye shunts
 - D. Kommunikantni vein
 - E. Arterioles
1146. At obliterating endartereiite affected:
- A. *Peripheral artery
 - B. Arteriovenous shunts
 - C. Kommunikantnye vein
 - D. Aorta and arteries
 - E. Sural vein
1147. The leading factor in the development of atherosclerotic lesions is:
- A. *Violation of cholesterol-lipid
 - B. Violation of protein metabolism
 - C. Suprarenalism
 - D. Improving the function of the sympathetic system
 - E. Violation of mineral metabolism
1148. B-lipoproteins show:
- A. *Antiplatelet effect
 - B. Atherogenic effect
 - C. Spasmolytic
 - D. Antiatherogenic effect
 - E. Surfactant effect
1149. Alpha-lipoproteins has:
- A. *Atherogenic effect
 - B. Antiatherogenic effect
 - C. Anticoagulant activity
 - D. Antiplatelet effect
 - E. Surfactant effect
1150. At obliterative atherosclerosis of lower limb arteries performed:
- A. *Bypass surgery, prostheses, endarterectomy
 - B. Leriche's operation, Oppel
 - C. Linton's operation
 - D. Babcock's operation

- E. Troyanov – Trandelenburg’s operation
1151. The most severe complication after reconstructive operations on the major arteries are:
- A. *Bleeding
 - B. Suppuration
 - C. Thrombosis
 - D. Chylorrhea
 - E. Phlebeurysm
1152. At occlusive disease of the lower extremities performed :
- A. *Lumbar sympathectomy, Leriche's operation
 - B. Linton’s operation
 - C. Bypass surgery
 - D. Intimectomy
 - E. Troyanov – Trandelenburg’s operation
1153. What are the indications for lumbar sympathectomy at obliterating endarterite?
- A. *Stage II
 - B. Stage IV
 - C. Gangrene of the lower extremity
 - D. Deep venous thrombosis
 - E. The duration of reactive hyperemia was more than 3 minutes
1154. At segmental occlusion of the bifurcation of the femoral artery what operation is performed:
- A. *Endarterectomy of the femoral artery
 - B. Bifurcation bypass surgery
 - C. Iliac-femoral bypass surgery
 - D. Saphenectomy
 - E. Artery ligation
1155. At segmental occlusion of the superficial femoral artery what operation is performed:
- A. *Autogenous vein bypass
 - B. Endarterectomy of the femoral artery
 - C. Iliac-femoral bypass surgery
 - D. Saphenectomy
 - E. Artery ligation
1156. At segmental occlusion of the popliteal artery what operation is performed:
- A. *Autogenous vein bypass
 - B. Endarterectomy of the femoral artery
 - C. Iliac-femoral bypass surgery
 - D. Saphenectomy
 - E. Artery ligation
1157. At segmental occlusion of the iliac artery what operation is performed:
- A. *Iliac-femoral aloshuntirovanie
 - B. Autogenous vein bypass
 - C. Endarterectomy of the femoral artery
 - D. Saphenectomy
 - E. Artery ligation
1158. Endarterectomy is performed at:
- A. *Atherosclerosis obliterans
 - B. Occlusive disease
 - C. Varicose
 - D. Deep vein thrombosis
 - E. Lymphedema
1159. Iliac-femoral bypass surgery performed at:
- A. *Atherosclerosis obliterans
 - B. Occlusive disease
 - C. Varicose
 - D. Deep vein thrombosis

- E. Lymphedema
1160. Femoropopliteal autovenous bypass surgery is performed at :
- A. *Atherosclerosis obliterans
 - B. Occlusive disease
 - C. Varicose
 - D. Deep vein thrombosis
 - E. Lymphedema
1161. Aorto-femoral bifurcation bypass surgery performed at:
- A. *Atherosclerosis obliterans
 - B. Occlusive disease
 - C. Varicose
 - D. Deep vein thrombosis
 - E. Lymphedema
1162. Decompression osteoperforation performed at:
- A. *Atherosclerosis obliterans
 - B. Coxarthrosis
 - C. Varicose
 - D. Deep vein thrombosis
 - E. Lymphedema
1163. Sympathectomy performed at:
- A. *Occlusive disease
 - B. Atherosclerosis obliterans
 - C. Varicose
 - D. Deep vein thrombosis
 - E. Lymphedema
1164. What is the normal number of platelets in the blood?
- A. *180-320
 - B. 20-40
 - C. 40-120
 - D. 420-650
 - E. 600-1000
1165. What phase hemocoagulation inhibits heparin:
- A. *Only the formation of thrombin
 - B. No right answer
 - C. Only the formation of fibrin
 - D. Only the formation of thromboplastin
 - E. It operates on the phase of thrombotic
1166. By indirect anticoagulants include:
- A. *Preparation of 4-oksikumarina
 - B. Preparations of alkaloids
 - C. Fibrinolytic drugs
 - D. Pentoksifilin
 - E. Thrombolytic drugs
1167. Absolute contraindications to anticoagulation attributes is:
- A. *Bleeding of any location, hemorrhagic diathesis
 - B. Aplastic anemia
 - C. Respiratory failure
 - D. Cardiovascular insufficiency
 - E. Lack of cerebral circulation
1168. Methods control of coagulation and fibrinolytic systems of blood:
- A. *Coagulogramm
 - B. Complete blood count
 - C. Determination of the rate of local blood flow
 - D. Blood count

- E. Biochemical analysis of blood
1169. What vessels are usually affected by atherosclerosis obliterans?
A. *Aorta and arteries
B. Arterioles
C. Microcirculatory bed
D. Superficial veins
E. Deep veins
1170. What is the morphological basis of atherosclerotic lesions?
A. *The accumulation of lipids in the intima
B. Thrombosis
C. Inflammatory process
D. Embolism
E. Aneurysm
1171. What is the main cause of atherosclerotic lesions?
A. *Hypercholesterolemia, dyslipoproteinemia
B. Infection
C. Trauma
D. Rheumatism, endocarditis
E. Myocardial infarction
1172. What principle is the basis classification of ischemic tissues in acute arterial obstruction?
A. *Clinical manifestations of ischemic tissues.
B. The residual blood flow in the limbs.
C. No ripple on the main arteries.
D. Segmental principle
E. The level of occlusion
1173. Specify non-pharmacological methods of correcting blood coagulation system.
A. Hemodilution.
B. Hemodialysis.
C. Hemosorption.
D. Artificial diuresis.
E. Limphosorbtsion.
1174. What are the contrast agents used for angiography?
A. *Triiodtrast, verografin.
B. Barium sulfate.
C. Methylene blue.
D. Alprostan.
E. Vasoprostan.
1175. In stage III acute obstruction of major arteries embolectomy completed:
A. *Fasciotomy
B. Operation Linton
C. Troyanov-Trendelenburg's operation
D. Modelung's operation
E. Kokket's operation
1176. The direct anticoagulant is
A. Heparin.
B. Phenilin, Omephin.
C. Nicotinic acid.
D. Streptokinase.
E. Acetylsalicylic acid.
1177. In case of overdose of heparin used:
A. *Protamine sulfate.
B. Rheopolyglucine.
C. Albumin.
D. Phibrinolysin.

- E. 10% glucose solution.
1178. For embolectomy used:
- *Fogarty probe .
 - Dzhadkins catheter .
 - Babcock's vein stripper.
 - Nelaton's probe .
 - Blekmor's probe
1179. Best results embolectomy occur during an operation in the first place:
- *6 hours.
 - 48 hours.
 - 8:00.
 - 24 hours.
 - 12 hours.
1180. What are the methods embolectomy arteries?
- *Direct and indirect embolectomy .
 - Fasciotomy.
 - Intimtrombektomiya.
 - Shunting.
 - Endarterectomy.
1181. Indicate the surgical treatment acute thrombosis of major arteries.
- Intimtrombectomy, thrombectomy, bypass surgery.
 - Embolectomy.
 - Fasciotomy.
 - Sympathectomy.
 - Leriche's operation.
1182. Types embolectomy :
- *Direct, indirect
 - Retrograde
 - Full, partial
 - Open, half closed, closed
 - Rising
1183. The most frequent cause of arterial thrombosis is:
- *Blood disease
 - Obliterating atherosclerosis
 - Trauma
 - Aneurysm
 - Diabetes mellitus
1184. To angiographic signs embolisation of major arteries relates:
- *Uniform narrowing of major vessels
 - Breaking contrast, poorer collateral channel, the absence of signs of atherosclerosis
 - The dramatic expansion of the main vessel
 - Pronounced collateral blood flow
 - Phlebeurysm
1185. To angiographic signs of acute thrombosis the major arteries include:
- *Aneurysmal expansion of arteries
 - Weak collateral blood flow
 - Slanted posted line break contrast, unequal contours of the arteries, developed collateral network
 - Uneven, serrated contours artery
 - Phlebeurysm
1186. Severe pallor of skin is characteristic for:
- *Artery Embolism
 - Varicose
 - Deep phlebothrombosis

- D. Postthrombophlebitic syndrome
 - E. Phlegmon limb
1187. Expressed cold extremities is characteristic for:
- A. *Arterial thrombosis
 - B. Varicose
 - C. Deep phlebothrombosis
 - D. Postthrombophlebitic syndrome
 - E. Phlegmon limb
1188. Full anesthesia limbs is characteristic for:
- A. *Arterial thrombosis
 - B. Varicose
 - C. Deep phlebothrombosis
 - D. Postthrombophlebitic syndrome
 - E. Phlegmon limb
1189. The absence pulsations on the extremities is characteristic for :
- A. *Arterial thrombosis
 - B. Varicose
 - C. Deep phlebothrombosis
 - D. Postthrombotic syndrome
 - E. Phlegmon limb
1190. Embolectomy performed at:
- A. *Artery Embolism
 - B. Varicose
 - C. Deep vein thrombosis
 - D. Postthrombotic syndrome
 - E. Phlegmon limb
1191. Trombintimectomy performed at:
- A. *Arterial thrombosis
 - B. Deep vein thrombosis
 - C. Artery Embolism
 - D. Subcutaneous thrombophlebitis
 - E. Varicose
1192. Autovenous bypass grafting is performed when:
- A. *Arterial thrombosis
 - B. Deep vein thrombosis
 - C. Artery Embolism
 - D. Subcutaneous thrombophlebitis
 - E. Varicose
1193. Thrombolytic therapy is indicated for:
- A. *Arterial thrombosis
 - B. Extremity lymphedema
 - C. Artery Embolism
 - D. Subcutaneous thrombophlebitis
 - E. Varicose
1194. Acute myocardial infarction is a risk factor:
- A. *Artery Embolism
 - B. Arterial thrombosis
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
1195. Bacterial endocarditis is a risk factor:
- A. *Artery Embolism
 - B. Arterial thrombosis
 - C. Varicose

- D. Phlegmon limb
- E. Postthrombotic syndrome
- 1196. Rheumatic heart disease is a risk factor:
 - A. *Artery Embolism
 - B. Arterial thrombosis
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1197. Abdominal aortic aneurysm is a risk factor for:
 - A. *Artery Embolism
 - B. Arterial thrombosis
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1198. Atrial fibrillation is a risk factor:
 - A. *Artery Embolism
 - B. Arterial thrombosis
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1199. Cardiac fibrillation is a risk factor:
 - A. *Artery Embolism
 - B. Arterial thrombosis
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1200. Obliterating atherosclerosis is a risk factor:
 - A. *Arterial thrombosis
 - B. Artery Embolism
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1201. Closed trauma limb is risk factor:
 - A. *Arterial thrombosis
 - B. Artery Embolism
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1202. Systemic lupus erythematosus is a risk factor:
 - A. *Arterial thrombosis
 - B. Embolism
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1203. Acute leukemia is a risk factor:
 - A. *Arterial thrombosis
 - B. Artery Embolism
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1204. Extravascular compression is a risk factor:
 - A. *Arterial thrombosis
 - B. Artery Embolism
 - C. Varicose

- D. Phlegmon limb
 - E. Postthrombotic syndrome
1205. Severe pallor of skin is characteristic for:
- A. *No right answer
 - B. Varicose
 - C. Deep phlebothrombosis
 - D. Postthrombotic syndrome
 - E. Phlegmon limb
1206. Expressed cold extremities is characteristic for:
- A. *No right answer
 - B. Varicose
 - C. Deep phlebothrombosis
 - D. Postthrombotic syndrome
 - E. Phlegmon limb
1207. Full anesthesia limbs characteristic:
- A. *No right answer
 - B. Varicose
 - C. Deep phlebothrombosis
 - D. Postthrombotic syndrome
 - E. Phlegmon limb
1208. The absence pulsations on the extremities artery is characteristic for:
- A. *No right answer
 - B. Varicose
 - C. Deep phlebothrombosis
 - D. Postthrombotic syndrome
 - E. Phlegmon limb
1209. Embolectomy performed at:
- A. *No right answer
 - B. Varicose
 - C. Deep phlebothrombosis
 - D. Posttromboflebitichnogo syndrome
 - E. Phlegmon limb
1210. Trombintimectomy performed at:
- A. *No right answer
 - B. Deep vein thrombosis
 - C. Artery Embolism
 - D. Subcutaneous thrombophlebitis
 - E. Varicose
1211. Autovenous bypass grafting is performed when:
- A. *No right answer
 - B. Deep vein thrombosis
 - C. Artery Embolism
 - D. Subcutaneous thrombophlebitis
 - E. Varicose
1212. Thrombolytic therapy is indicated for:
- A. *No right answer
 - B. Extremity lymphedema
 - C. Artery Embolism
 - D. Subcutaneous thrombophlebitis
 - E. Varicose
1213. Acute myocardial infarction is a risk factor:
- A. *No right answer
 - B. Arterial thrombosis
 - C. Varicose

- D. Phlegmon limb
- E. Postthrombotic syndrome
- 1214. Bacterial endocarditis is a risk factor:
 - A. *No right answer
 - B. Arterial thrombosis
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1215. Rheumatic heart disease is a risk factor:
 - A. *No right answer
 - B. Arterial thrombosis
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1216. Abdominal aortic aneurysm is a risk factor:
 - A. *No right answer
 - B. Arterial thrombosis
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1217. Atrial fibrillation is a risk factor:
 - A. *No right answer
 - B. Arterial thrombosis
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1218. Cardiac fibrillation is a risk factor:
 - A. *No right answer
 - B. Arterial thrombosis
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1219. Obliterating atherosclerosis is a risk factor:
 - A. *No right answer
 - B. Artery Embolism
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1220. Closed trauma limb risk factor:
 - A. *No right answer
 - B. Artery Embolism
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1221. Systemic lupus erythematosus is a risk factor:
 - A. *No right answer
 - B. Embolism
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1222. Acute leukemia is a risk factor:
 - A. *No right answer
 - B. Artery Embolism
 - C. Varicose

- D. Phlegmon limb
- E. Postthrombotic syndrome
- 1223. Extra vessels artery compression is a risk factor:
 - A. *Arterial thrombosis
 - B. Artery Embolism
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1224. Angiography is a procedure risk factor:
 - A. *Arterial thrombosis
 - B. Artery Embolism
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1225. Angiography is a procedure risk factor:
 - A. *No right answer
 - B. Artery Embolism
 - C. Varicose
 - D. Phlegmon limb
 - E. Postthrombotic syndrome
- 1226. What drugs belong to a direct anticoagulant?
 - A. *Fraxiparine,
 - B. Sinkumar,
 - C. Streptokinase,
 - D. Trental,
 - E. Diclofenac,
- 1227. What drugs belong to the indirect anticoagulants?
 - A. *Sinkumar
 - B. Fraxiparine
 - C. Streptokinase
 - D. Trental
 - E. Diclofenac
- 1228. What drugs belong to fibrinolytics?
 - A. *Streptokinase, urokinase
 - B. Heparin
 - C. Sinkumar, fenilin
 - D. Trental, Pentoksifilin
 - E. Diclofenac, Naklofen
- 1229. What is initial dose Streptokinase?
 - A. *250000 units
 - B. 5000
 - C. 10000 points
 - D. 100000 units
 - E. 1000000 Units
- 1230. What drug is used in the overdose of heparin?
 - A. *Protamine sulfate
 - B. Fraxiparine
 - C. Streptokinase
 - D. Trental
 - E. Diclophenac
- 1231. Which drug is used in the overdose of heparin?
 - A. *No right answer
 - B. Fraxiparine
 - C. Streptokinase

- D. Trental
 - E. Diclophenac
1232. What drug is used in an overdose of streptokinase?
- A. *Aminocaproic acid, trasylol
 - B. Fraxiparine, Clexane
 - C. Protamine sulfate
 - D. Trental, Pentoksifilin
 - E. Diclofenac, Naklofen
1233. What is normal prothrombin index?
- A. *85-100%
 - B. 10-20%
 - C. 30-60%
 - D. 50-70%
 - E. 100-120%
1234. What are the indicators of coagulation control dosing of anticoagulants?
- A. *Prothrombin index
 - B. The number of platelets in the blood
 - C. The level of plasma fibrinogen
 - D. Trombotest
 - E. Plasma recalcification time
1235. What is the normal level of plasma fibrinogen?
- A. *2-4 g / l
 - B. 6.8 grams / liter
 - C. 10-16 grams / liter
 - D. 30-50 grams / liter
 - E. 75-100 grams / liter
1236. What are the indicators of coagulation control dosing of thrombolytics?
- A. *The level of plasma fibrinogen
 - B. The number of platelets in the blood
 - C. Prothrombin index
 - D. Thrombotest
 - E. Plasma recalcification time
1237. What are the normal values of plasma recalcification time?
- A. *60-120 seconds
 - B. 0.5-2 seconds
 - C. 10-40 seconds
 - D. 40-60 seconds
 - E. 4-8 minutes
1238. What are the normal rates thrombotest?
- A. *IV-V degree
 - B. I-II degree
 - C. II-III degree
 - D. VI-VIII degree
 - E. X-XII level
1239. What is the normal number of platelets in the blood?
- A. *180-320 10⁹ / l
 - B. 20-40 10⁹ / l
 - C. 40-120 10⁹ / l
 - D. 420-650 10⁹ / l
 - E. 600-1000 10⁹ / l
1240. What phase hemocoagulation inhibits heparin:
- A. *Only the formation of thrombin
 - B. No right answer
 - C. Only the formation of fibrin

- D. Only the formation of thromboplastin
- E. It operates on the phase of thrombotic
- 1241. Indirect anticoagulants include:
 - A. *Preparation of 4-oksikumarina
 - B. Preparations of alkaloids
 - C. Fibrinolytic drugs
 - D. Pentoksiphylin
 - E. Thrombotic drugs
- 1242. The absolute contraindication of anticoagulants include:
 - A. *Bleeding of any location, hemorrhagic diathesis
 - B. Aplastic anemia
 - C. Respiratory failure
 - D. Cardiovascular insufficiency
 - E. Lack of cerebral circulation
- 1243. Activators of fibrinolysis include:
 - A. *Nicotinic acid, Complamin
 - B. Phenilin, Omefin
 - C. Gastrotsepin, Venter
 - D. Vitamin B
 - E. Vitamins A, C
- 1244. Preparations thrombolytic action are:
 - A. *Phibrinolysin, celiasa, streptokinase
 - B. Strophanthus
 - C. Tselonid, lantozid
 - D. Rheopolyglucine, poliglucin
 - E. Trental
- 1245. Methods of control the coagulation and fibrinolytic systems of blood:
 - A. *Coagulogramm
 - B. Complete blood
 - C. Determination of the rate of local blood flow
 - D. Blood count
 - E. Biochemical analysis of blood
- 1246. At bleeding caused by anticoagulants of indirect action shall appoint:
 - A. *Vicasol
 - B. Pipolphen
 - C. Digitoxin
 - D. Hydrocortisone
 - E. Pentoksiphilin
- 1247. Clinical signs the embolism arteries in the first hours is
 - A. Severe pain in the limbs
 - B. Dizziness
 - C. Nausea
 - D. Limb gangrene
 - E. Dystonia
- 1248. Clinical signs the embolism arteries in the first hours
 - A. Cold extremities
 - B. Dizziness
 - C. Nausea
 - D. Limb gangrene
 - E. Dystonia
- 1249. Clinical signs the arteries embolism in the first hours is
 - A. Severe weakness of the affected limb
 - B. Dizziness
 - C. Nausea

- D. Limb gangrene
 - E. Dystonia
1250. Clinical signs the arteries embolism in the first hours is
- A. Paleness of the skin of the affected limb
 - B. Dizziness
 - C. Nausea
 - D. Limb gangrene
 - E. Dystonia
1251. Clinical signs the arteries embolism in the first hours is
- A. The deterioration of the picture subcutaneous veins of the affected limb
 - B. Dizziness
 - C. Nausea
 - D. Limb gangrene
 - E. Dystonia
1252. Clinical signs the arteries embolism in the first hours is
- A. Changing the surface sensitivity of the affected limb
 - B. Dizziness
 - C. Nausea
 - D. Limb gangrene
 - E. Dystonia
1253. Clinical signs the arteries embolism in the first hours is
- A. Changing the deep sensitivity of the affected limb
 - B. Dizziness
 - C. Nausea
 - D. Limb gangrene
 - E. Dystonia
1254. Clinical signs the arteries embolism in the first hours is
- A. Violation of the function of the affected limb
 - B. Dizziness
 - C. Nausea
 - D. Limb gangrene
 - E. Dystonia
1255. Clinical signs the arteries embolism in the first hours is
- A. The disappearance of pulsation of the arteries to the level of obstruction
 - B. Dizziness
 - C. Nausea
 - D. Limb gangrene
 - E. Dystonia
1256. Clinical signs the arteries embolism in the first hours is
- A. No right answer
 - B. Dizziness
 - C. Nausea
 - D. Limb gangrene
 - E. Dystonia
1257. At occlusion of the bifurcation aorta region of ischemia captures
- A. Both legs and lower abdomen
 - B. Lower limb to crural arch
 - C. Lower extremity to the middle third of the thigh
 - D. Lower extremity to the knee
 - E. Foot
1258. When occlusion of the bifurcation of the aorta region of ischemia captures
- A. No right answer
 - B. Lower limb to crural arch
 - C. Lower extremity to the middle third of the thigh

- D. Lower extremity to the knee
- E. Foot
- 1259. At occlusion of iliac artery ischemia region captures
 - A. Lower limb to crural arch
 - B. Both legs and lower abdomen
 - C. Lower extremity to the middle third of the thigh
 - D. Lower extremity to the knee
 - E. Foot
- 1260. When occlusion of iliac artery ischemia region captures
 - A. No right answer
 - B. Both legs and lower abdomen
 - C. Lower extremity to the middle third of the thigh
 - D. Lower extremity to the knee
 - E. Foot
- 1261. At occlusion of the femoral artery ischemia region captures
 - A. Lower extremity to the middle third of the thigh
 - B. Lower limb to crural arch
 - C. Both legs and lower abdomen
 - D. Lower extremity to the knee
 - E. Foot
- 1262. At occlusion of the femoral artery ischemia region captures
 - A. No right answer
 - B. Lower limb to crural arch
 - C. Both legs and lower abdomen
 - D. Lower extremity to the knee
 - E. Foot
- 1263. At occlusion of the popliteal artery ischemia region captures
 - A. Lower extremity to the middle third of the thigh
 - B. Lower limb to crural arch
 - C. Both legs and lower abdomen
 - D. Lower extremity to the knee
 - E. Foot
- 1264. At occlusion of the popliteal artery ischemia region captures
 - A. No right answer
 - B. Lower extremity to the middle third of the thigh
 - C. Lower limb to crural arch
 - D. Both legs and lower abdomen
 - E. Foot
- 1265. At occlusion of the popliteal artery ischemia region captures
 - A. Lower extremity to the knee
 - B. Lower extremity to the middle third of the thigh
 - C. Lower limb to crural arch
 - D. Both legs and lower abdomen
 - E. Foot
- 1266. At occlusion of the subclavian artery ischemia region captures
 - A. All hand
 - B. Arm to the upper third of the shoulder
 - C. Hand until the middle third of the shoulder
 - D. Both hands
 - E. Brush
- 1267. When occlusion of the subclavian artery ischemia region captures
 - A. No right answer
 - B. Arm to the upper third of the shoulder
 - C. Hand until the middle third of the shoulder

- D. Both hands
 - E. Brush
1268. When occlusion of the axillary artery ischemia region captures
- A. Arm to the upper third of the shoulder
 - B. All hand
 - C. Hand until the middle third of the shoulder
 - D. Both hands
 - E. Brush
1269. At occlusion of the axillary artery ischemia region captures
- A. No right answer
 - B. All hand
 - C. Hand until the middle third of the shoulder
 - D. Both hands
 - E. Brush
1270. At occlusion of the brachial artery area of ischemia captures
- A. Hand until the middle third of the shoulder
 - B. All hand
 - C. Arm to the upper third of the shoulder
 - D. Both hands
 - E. Brush
1271. At occlusion of the brachial artery area of ischemia captures
- A. No right answer
 - B. All hand
 - C. Arm to the upper third of the shoulder
 - D. Both hands
 - E. Brush
1272. How many days can occur secondary deep vein thrombosis limb?
- A. *3-6 days
 - B. 1-2 days
 - C. 7-8 days
 - D. 7-10 days
 - E. 14 days
1273. How many days can occur secondary deep vein thrombosis limb?
- A. *No right answer
 - B. 1-2 days
 - C. 7-8 days
 - D. 7-10 days
 - E. 14 days
1274. Arterial thrombosis developed on the background:
- A. *Atherosclerotic lesions
 - B. Ulcer
 - C. Chronic pancreatitis
 - D. Ulcerative colitis
 - E. Chronic gastritis
1275. Arterial thrombosis developed on the background:
- A. *Obliterative endarteritis
 - B. Ulcer
 - C. Chronic pancreatitis
 - D. Ulcerative colitis
 - E. Chronic gastritis
1276. Arterial thrombosis developed on the background:
- A. *Nonspecific aortoarteriitis
 - B. Ulcer
 - C. Chronic pancreatitis

- D. Ulcerative colitis
- E. Chronic gastritis
- 1277. Arterial thrombosis developed on the background:
 - A. *Infectious Diseases
 - B. Ulcer
 - C. Chronic pancreatitis
 - D. Ulcerative colitis
 - E. Chronic gastritis
- 1278. Arterial thrombosis developed on the background:
 - A. *Erythrocytosis
 - B. Ulcer
 - C. Chronic pancreatitis
 - D. Ulcerative colitis
 - E. Chronic gastritis
- 1279. Arterial thrombosis developed on the background:
 - A. *Hypercoagulation
 - B. Ulcer
 - C. Chronic pancreatitis
 - D. Ulcerative colitis
 - E. Chronic gastritis
- 1280. How long is the reversible phase change?
 - A. *2-3 hours
 - B. 3-5 hours
 - C. 5-6 hours
 - D. 7-8 hours
 - E. 10-12 hours
- 1281. How long is the reversible phase change?
 - A. *No right answer
 - B. 3-5 hours
 - C. 5-6 hours
 - D. 7-8 hours
 - E. 10-12 hours
- 1282. How long is the growth phase of irreversible changes
 - A. 5-6 hours
 - B. 2-3 hours
 - C. 3-5 hours
 - D. 7-8 hours
 - E. 10-12 hours
- 1283. How long is the growth phase of irreversible changes
 - A. No right answer
 - B. 2-3 hours
 - C. 3-5 hours
 - D. 7-8 hours
 - E. 10-12 hours
- 1284. For the diagnosis of embolism of arteries of extremities most informative method is:
 - A. *Doppler ultrasound
 - B. Rheovasography
 - C. Radiography limbs
 - D. ECG
 - E. Echocardiography
- 1285. To diagnose thrombosis of arteries most informative method is:
 - A. *Doppler ultrasound
 - B. Rheovasography
 - C. Radiography limbs

- D. ECG
 - E. Echocardiography
1286. For the diagnosis embolism of arteries the extremities most informative method is:
- A. *Arteriography
 - B. Rheovasography
 - C. Radiography limbs
 - D. ECG
 - E. Echocardiography
1287. For the diagnosis embolism of arteries the extremities most informative method is:
- A. *No right answer
 - B. Rheovasography
 - C. Radiography limbs
 - D. ECG
 - E. Echocardiography
1288. At arteries embolism differential diagnosis must be with:
- A. *Arterial spasm
 - B. Deep vein thrombosis
 - C. Lymphadenitis
 - D. Coxarthrosis
 - E. Strangulated hernia
1289. When embolism arteries differential diagnosis must be with:
- A. *Acute heart failure on a background of obliterating arterial diseases
 - B. Deep vein thrombosis
 - C. Lymphadenitis
 - D. Coxarthrosis
 - E. Strangulated hernia
1290. At arteries embolism differential diagnosis must be with:
- A. *Stratification of abdominal aortic aneurysm
 - B. Deep vein thrombosis
 - C. Lymphadenitis
 - D. Coxarthrosis
 - E. Strangulated hernia
1291. At arteries embolism differential diagnosis must be with:
- A. *Acute transverse poliomyelitis
 - B. Deep vein thrombosis
 - C. Lymphadenitis
 - D. Coxarthrosis
 - E. Strangulated hernia
1292. When embolism arteries differential diagnosis must be with:
- A. *No right answer
 - B. Deep vein thrombosis
 - C. Lymphadenitis
 - D. Coxarthrosis
 - E. Strangulated hernia
1293. Absolute contraindication for surgical treatment of embolism is:
- A. *Agony state of patients
 - B. Angina
 - C. Transient ischemic attack
 - D. Fracture limb
 - E. Heart disease
1294. Absolute contraindication for surgical treatment of embolism is:
- A. *Total contracture limb
 - B. Angina
 - C. Transient ischemic attack

- D. Fracture limb
- E. Heart disease
- 1295. Absolute contraindication for surgical treatment of embolism is:
 - A. *Limb gangrene
 - B. Angina
 - C. Transient ischemic attack
 - D. Fracture limb
 - E. Heart disease
- 1296. Absolute contraindication for surgical treatment of embolism is:
 - A. *Critically ill patients with a mild degree of ischemia
 - B. Angina
 - C. Transient ischemic attack
 - D. Fracture limb
 - E. Heart disease
- 1297. Relative contraindications to operation at a mild degree of acute limb ischemia and the absence of its progression is
 - A. Acute myocardial infarction
 - B. Angina
 - C. Varicose disease
 - D. PTFS
 - E. Angiodysplasia
- 1298. Relative contraindications to operation at a mild degree of acute limb ischemia and the absence of its progression is
 - A. Insult
 - B. Angina
 - C. Varicose disease
 - D. PTFS
 - E. Angiodysplasia
- 1299. Relative contraindications to operation at a mild degree of acute limb ischemia and the absence of its progression is
 - A. Inoperable tumor
 - B. Angina
 - C. Varicose disease
 - D. PTFS
 - E. Angiodysplasia
- 1300. Relative contraindications to operation at a mild degree of acute limb ischemia and the absence of its progression is
 - A. No right answer
 - B. Angina
 - C. Varicose disease
 - D. PTFS
 - E. Angiodysplasia
- 1301. For elimination spasm in acute arterial insufficiency using:
 - A. *Papaverine
 - B. Alprostan
 - C. Heparin
 - D. Warfarin
 - E. Dimexide
- 1302. For elimination spasm in acute arterial insufficiency using:
 - A. *No-shpa
 - B. Alprostan
 - C. Heparin
 - D. Warfarin
 - E. Dimexide

1303. The elimination of spasm in acute arterial insufficiency using:
- A. *Halidor
 - B. Alprostan
 - C. Heparin
 - D. Warfarin
 - E. Dimexide
1304. Radical operation in acute arterial insufficiency include:
- A. *Embolintimtrmbectomy
 - B. Thoracic sympathectomy
 - C. Transverse sympathectomy
 - D. Periarterial simpaectomy
 - E. Amputation
1305. Radical operation in acute arterial insufficiency include:
- A. *Intimectomy
 - B. Thoracic sympathectomy
 - C. Transverse sympathectomy
 - D. Periarterial simpaectomy
 - E. Amputation
1306. Radical operation in acute arterial insufficiency include:
- A. *Shunt surgery
 - B. Thoracic sympathectomy
 - C. Transverse sympathectomy
 - D. Periarterial sympathectomy
 - E. Amputation
1307. Radical operation in acute arterial insufficiency include:
- A. *Resection of the artery with prosthetic
 - B. Thoracic sympathectomy
 - C. Transverse sympathectomy
 - D. Periarterial sympathectomy
 - E. Amputation
1308. Radical operation in acute arterial insufficiency include:
- A. *Plasticity of arterial wall with patches
 - B. Thoracic sympathectomy
 - C. Transverse sympathectomy
 - D. Periarterial sympathectomy
 - E. Amputation
1309. To palliative surgery for acute arterial insufficiency include:
- A. *Periarterial sympaectomy
 - B. Plasticity of arterial wall with patches
 - C. Resection artery prosthetic
 - D. Shunt surgery
 - E. Endarterectomy
1310. To palliative surgery for acute arterial insufficiency include:
- A. *Transverse sympathectomy
 - B. Plasticity of arterial wall with patches
 - C. Resection artery prosthetic
 - D. Shunt surgery
 - E. Endarterectomy
1311. To palliative surgery for acute arterial insufficiency include:
- A. *Amputation
 - B. Plasticity of arterial wall with patches
 - C. Resection artery prosthetic
 - D. Shunt surgery
 - E. Endarterectomy

1312. Types embolectomy
- A. Straight
 - B. Oblique
 - C. Transverse
 - D. Ring
 - E. No right answer
1313. Types embolectomy
- A. Indirect
 - B. Oblique
 - C. Transverse
 - D. Ring
 - E. No right answer
1314. For secondary prevention thrombosis during the operation in the vascular bed is introduced
- A. Heparin
 - B. Solcoseryl
 - C. Vicasol
 - D. Actovegin
 - E. No-shpa
1315. For secondary prevention of thrombosis during the operation in the vascular bed is introduced
- A. No right answer
 - B. Solcoseryl
 - C. Vicasol
 - D. Actovegin
 - E. No-shpa
1316. For secondary prevention of thrombosis during the operation in the vascular bed is introduced at a dose of heparin:
- A. *5000
 - B. 10000
 - C. 1000
 - D. 7000
 - E. 9000
1317. Shunting operations include
- A. Femoropopliteal bypass
 - B. Endarterectomy
 - C. Saphenectomy
 - D. Fasciotomy
 - E. Ganglionectomy
1318. Shunting operations include
- A. Femoropopliteal bypass autovenous
 - B. Endarterectomy
 - C. Saphenectomy
 - D. Fasciotomy
 - E. Ganglionectomy
1319. What volume of blood flows through superficial veins?
- A. *10-15 %
 - B. 5 %
 - C. 30-40 %
 - D. 70-80 %
 - E. 90 %
1320. Where does a great saphenous vein drain in?
- A. *Femoral vein
 - B. The veins of shin
 - C. Popliteal vein

- D. External iliac vein
 - E. Vena cava inferior
1321. Where does a small saphenous vein drain in?
- A. *Popliteal vein
 - B. Vena cava inferior
 - C. External iliac vein
 - D. Femoral vein
 - E. The veins of shin
1322. The localization of great saphenous vein inflow is:
- A. *2-3 sm. below inguinal ligament
 - B. In upper third of the lower extremity
 - C. In a popliteal fossa
 - D. In lower third of thigh
 - E. In a lumbar area
1323. The localization of small saphenous vein inflow is:
- A. *In a popliteal fossa
 - B. In upper third of the lower extremity
 - C. In lower third of thigh
 - D. 2-3 sm. below inguinal ligament
 - E. In a lumbar area
1324. What veins belongs to the superficial system?
- A. *Small and great saphenous vein
 - B. The veins of shin
 - C. Superficial and deep femoral vein
 - D. Brachial veins
 - E. Elbow and radial veins
1325. What veins belongs to the deep system?
- A. *V. radialis
 - B. Small saphenous vein
 - C. Great saphenous vein
 - D. V. basilica
 - E. V. cephalica
1326. What factor prevails in the development of primary varicosity?
- A. *Weakness of connecting tissue of vessels
 - B. Arterio-venous fistulas
 - C. Venous hypoplasia
 - D. Diabetes mellitus
 - E. Obliterative atherosclerosis
1327. What are the hormonal changes contribute to the development of varicosity?
- A. *Pregnancy
 - B. Diabetes mellitus
 - C. Thyrotoxicosis
 - D. Miksedema
 - E. Insufficiency of suprarenal glands
1328. What is the pathological basis of the development of chronic venous insufficiency?
- A. *Venous hypertension
 - B. Block of lymph outflow
 - C. Arterial ischemia
 - D. Hypertension
 - E. Disturbance of innervation
1329. What is the cause of hypertension in the venous system of lower extremities?
- A. *Venous valvular incompetence
 - B. Arterial ischemia
 - C. Hypertension

- D. Block of lymph outflow
 - E. Disturbance of innervation
1330. What does the venous valvular incompetence result in?
- A. *Venous hypertension
 - B. Arterial ischemia
 - C. Hypertension
 - D. Disturbance of innervation
 - E. Disturbance of lymph outflow
1331. What is the characteristic sign of the I stage of varicosity?
- A. *Heavy sensation
 - B. Transitory edema
 - C. Permanent edema
 - D. Hyperpigmentation
 - E. Trophic ulcer
1332. What is the characteristic sign of the IIA stage of varicosity?
- A. *Transitory edema
 - B. Heavy sensation
 - C. Permanent edema
 - D. Hyperpigmentation
 - E. Trophic ulcer
1333. What is the characteristic sign of the IIB stage of varicosity?
- A. *Hyperpigmentation
 - B. Heavy sensation
 - C. Transitory edema
 - D. Open trophic ulcer
 - E. Healed trophic ulcer
1334. What is the characteristic sign of the IIB stage of varicosity?
- A. *Permanent edema
 - B. Heavy sensation
 - C. Transitory edema
 - D. Open trophic ulcer
 - E. Healed trophic ulcer
1335. What is the characteristic sign of the III stage of varicosity?
- A. *Trophic ulcer
 - B. Heavy sensation
 - C. Transitory edema
 - D. Permanent edema
 - E. Hyperpigmentation
1336. What stage of chronic venous insufficiency is characterized by the sign of "heavy sensation"?
- A. *I
 - B. 0
 - C. IIA
 - D. IIB
 - E. III
1337. What stage of chronic venous insufficiency is characterized by the sign of a transitory edema?
- A. *IIA
 - B. 0
 - C. I
 - D. IIB
 - E. III
1338. What stage of chronic venous insufficiency is characterized by the sign of a permanent edema?

- A. *IIB
 - B. 0
 - C. I
 - D. IIA
 - E. III
1339. What stage of chronic venous insufficiency is characterized by the sign of a hyperpigmentation?
- A. *IIB
 - B. 0
 - C. I
 - D. IIA
 - E. III
1340. What stage of chronic venous insufficiency is characterized by the sign of lipodermatosclerosis?
- A. *IIB
 - B. 0
 - C. I
 - D. IIA
 - E. III
1341. What stage of chronic venous insufficiency is characterized by the sign of opened trophic ulcer?
- A. *III
 - B. 0
 - C. I
 - D. IIA
 - E. IIB
1342. What stage of chronic venous insufficiency is characterized by the sign of the healed trophic ulcer?
- A. *III
 - B. 0
 - C. I
 - D. IIA
 - E. IIB
1343. Which stage of chronic venous insufficiency is characterized by valvular incompetence of superficial veins?
- A. *I
 - B. 0
 - C. IIA
 - D. IIB
 - E. III
1344. Which stage of chronic venous insufficiency is characterized by valvular incompetence of superficial and perforative veins?
- A. *II
 - B. 0
 - C. I
 - D. III
 - E. IV
1345. Which stage of chronic venous insufficiency is characterized by valvular incompetence of superficial, perforative and deep veins?
- A. *IIB-III
 - B. 0
 - C. I
 - D. IIA
 - E. IV

1346. For varicosity of lower extremities is typical:
- A. *Heavy sensation
 - B. Intermittent claudication
 - C. Rest pains
 - D. Disappearance of sensation
 - E. Disappearance of movements
1347. For varicosity of lower extremities is typical:
- A. *Transitory edema of lower extremities
 - B. Intermittent claudication
 - C. Rest pains
 - D. Disappearance of sensation
 - E. Disappearance of movements
1348. For varicosity of lower extremities is typical:
- A. *Varicose veins
 - B. Cyanosis of the lower extremity
 - C. Pallor of the lower extremity
 - D. Disappearance of sensation
 - E. Disappearance of movements
1349. For varicosity of lower extremities is typical:
- A. *Lipodermatosclerosis of shin
 - B. Cyanosis of the lower extremity
 - C. Pallor of the lower extremity
 - D. Disappearance of sensation
 - E. Disappearance of movements
1350. For varicosity of lower extremities is typical:
- A. *Trophic ulcer of shin
 - B. Cyanosis of the lower extremity
 - C. Pallor of the lower extremity
 - D. Disappearance of sensation
 - E. Disappearance of movements
1351. For varicosity of lower extremities is typical:
- A. *Hyperpigmentation of shin
 - B. Cyanosis of the lower extremity
 - C. Pallor of the lower extremity
 - D. Disappearance of sensation
 - E. Disappearance of movements
1352. Heavy sensation of lower extremities is characteristic for:
- A. *Varicosity
 - B. Atherosclerosis obliterans
 - C. Thrombangiitis obliterans
 - D. Leriche's syndrome
 - E. Embolisms of femoral artery
1353. The transitory edema of lower extremities is characteristic for:
- A. *Varicosity
 - B. Atherosclerosis obliterans
 - C. Thrombangiitis obliterans
 - D. Leriche's syndrome
 - E. Embolisms of femoral artery
1354. Lipodermatosclerosis of the lower third of shin is characteristic for:
- A. *Varicosity
 - B. Atherosclerosis obliterans
 - C. Thrombangiitis obliterans
 - D. Leriche's syndrome
 - E. Embolisms of femoral artery

1355. The hyperpigmentation of the lower third of shin is characteristic for:
- A. *Varicosity
 - B. Atherosclerosis obliterans
 - C. Thrombangiitis obliterans
 - D. Leriche's syndrome
 - E. Embolisms of femoral artery
1356. The trophic ulcer of the lower third of shin is characteristic for:
- A. *Varicosity
 - B. Thrombosis of deep veins
 - C. Thrombangiitis obliterans
 - D. Leriche's syndrome
 - E. Embolisms of femoral artery
1357. What test is used for determination of valvular incompetence of superficial veins?
- A. *Troyanov-Trendelenburg's test
 - B. Talman's test
 - C. Pratt's test
 - D. Mayo-Pratt's test
 - E. Delbe-Pertess test (marching test)
1358. What test is used for determination of valvular incompetence of perforative veins?
- A. *Pratt's test
 - B. Troyanov-Trendelenburg's test
 - C. Gackenbruch's test
 - D. Homan's test
 - E. Delbe-Pertess test (marching test)
1359. What test is used for the estimation of the passability of deep veins?
- A. *Delbe-Pertess test (marching test)
 - B. Troyanov-Trendelenburg's test
 - C. Gackenbruch's test
 - D. Pratt's test
 - E. Talman's test
1360. The Troyanov-Trendelenburg's test is used in the diagnostics of:
- A. *Valvular incompetence of superficial veins
 - B. Valvular incompetence of perforative veins
 - C. Passability of deep veins
 - D. Deep vein thrombosis
 - E. Lymphedema of the extremity
1361. The Talman's test is used in the diagnostics of:
- A. *Valvular incompetence of perforative veins
 - B. Valvular incompetence of superficial veins
 - C. Passability of deep veins
 - D. Deep vein thrombosis
 - E. Lymphedema of the extremity
1362. The Pratt's test is used in the diagnostics of:
- A. *Valvular incompetence of perforative veins
 - B. Valvular incompetence of superficial veins
 - C. Passability of deep veins
 - D. Deep vein thrombosis
 - E. Lymphedema of the extremity
1363. The Mayo-Pratt's test is used in the diagnostics of:
- A. *Passability of deep veins
 - B. Valvular incompetence of perforative veins
 - C. Valvular incompetence of superficial veins
 - D. Deep vein thrombosis
 - E. Lymphedema of the extremity

1364. The Delbe-Pertess test (marching test) is used in the diagnostics of:
- A. *Passability of deep veins
 - B. Valvular incompetence of perforative veins
 - C. Valvular incompetence of superficial veins
 - D. Deep vein thrombosis
 - E. Lymphedema of the extremity
1365. What complication is typical for varicosity?
- A. *Subcutaneous thrombophlebitis
 - B. Arterial thrombosis
 - C. Paresis
 - D. Lymphostasis
 - E. Gangrene
1366. More frequently the subcutaneous thrombophlebitis develops as a result of:
- A. *Varicosity
 - B. Atherosclerosis obliterans
 - C. Lymphedema of lower extremities
 - D. Acute appendicitis
 - E. Acute cholecystitis
1367. What complication is typical for varicosity?
- A. *Trophic ulcer
 - B. Arterial thrombosis
 - C. Paresis
 - D. Plegia
 - E. Gangrene
1368. What is the basic method of the diagnostics of arterio-venous fistulas?
- A. *Phlebography
 - B. Coagulogram
 - C. Delbe-Pertess test (marching test)
 - D. Ultrasound examination
 - E. Arteriography
1369. What is the basic method of the diagnostics of venous angiodysplasia?
- A. *Phlebography
 - B. Coagulogram
 - C. Delbe-Pertess test (marching test)
 - D. Ultrasound examination
 - E. Arteriography
1370. A phlebography is used for the diagnostics of:
- A. *Arterio-venous fistulas
 - B. Atherosclerosis obliterans
 - C. Thrombangiitis obliterans
 - D. Lymphedema
 - E. Gynaecological pathology
1371. A phlebography is used for the diagnostics of:
- A. *Venous angiodysplasia
 - B. Atherosclerosis obliterans
 - C. Thrombangiitis obliterans
 - D. Lymphedema
 - E. Gynaecological pathology
1372. What method is used for the diagnostics of valvular incompetence of perforative and deep veins?
- A. *Ultrasound duplex scanning
 - B. Coagulogram
 - C. Reovasography
 - D. Ultrasound doppler examination

- E. Arteriography
1373. What method is used for the estimation of the passability of deep veins?
- A. *Ultrasound examination
 - B. Coagulogram
 - C. Reovasography
 - D. ECG
 - E. Arteriography
1374. What operation is performed for varicosity?
- A. *Saphenectomy
 - B. Thrombectomy
 - C. Ligation of vein
 - D. Endarterectomy
 - E. Femoro-popliteal by-passing
1375. What treatment is indicated in varicosity of the IIA stage?
- A. *Saphenectomy
 - B. Conservative treatment
 - C. Sclerotherapy
 - D. Troyanov-Trendelenburg's operation
 - E. Saphenectomy with the subfascial ligation of perforative veins (Linton's operation)
1376. What treatment is indicated for a noncomplicated varicosity?
- A. *Saphenectomy
 - B. Conservative treatment
 - C. Sclerotherapy
 - D. Troyanov-Trendelenburg's operation
 - E. Saphenectomy with the subfascial ligation of perforative veins (Linton's operation)
1377. To the real causes of varicosity relapse regard:
- A. *Remaining of main trunk, long stump of great saphenous vein
 - B. Thrombosis of vena cava inferior
 - C. Arterio-venous fistula
 - D. Insufficiency of the ostial valve
 - E. Thrombosis of iliac veins
1378. To the functional tests for the detection of valvular incompetence of superficial veins used:
- A. *Troyanov-Trendelenburg's test
 - B. Delbe-Pertess test (marching test)
 - C. Oppel's test
 - D. Pratt's test
 - E. Talman's test
1379. To the functional tests for the detection of valvular incompetence of perforative veins used:
- A. *Talman's test
 - B. Delbe-Pertess test (marching test)
 - C. Troyanov-Trendelenburg's test
 - D. Gackenbruch's test
 - E. Oppel's test
1380. To the functional tests for the detection of valvular incompetence of deep veins used:
- A. *Delbe-Pertess test (marching test)
 - B. Troyanov-Trendelenburg's test
 - C. Gackenbruch's test
 - D. Oppel's test
 - E. Talman's test
1381. What is the sequence of the saphenectomy performance?
- A. *Troyanov-Trendelenburg's operation, Beacock's, Linton's
 - B. Linton's operation, Cocketh's, Beacock's
 - C. Narath's operation, Beacock's, Cocketh's
 - D. Beacock's operation, Linton's, Troyanov-Trendelenburg's

- E. Bebcock's operation, Narath's, Cocketh's operation
1382. A maximal amount of perforative veins is located in:
- A. *Lower third of shin
 - B. Upper third of shin
 - C. Middle third of shin
 - D. Area of thigh
 - E. Lower third of thigh
1383. The contraindication for saphenectomy in varicosity is:
- A. *Obstruction of deep veins
 - B. Insufficiency of valves of perforative veins
 - C. Insufficiency of the ostial valve
 - D. Diffuse type of great saphenous vein
 - E. Valvular incompetence of sural veins
1384. For the saphenectomy operation used:
- A. *Bebcock's catheter
 - B. Blackmore's zond
 - C. Fogarti's catheter
 - D. Nelaton's catheter
 - E. Nasogastric zond
1385. What operations are performed on the perforative veins of lower extremities:
- A. *Linton's, Cocketh's operation
 - B. Bebcock's, Narath's
 - C. Troyanov-Trendelenburg's
 - D. Madelung's
 - E. Felder's
1386. To the indirect anticoagulants regard the medicines:
- A. *Fenilin, Omephin, Pelentan.
 - B. Tiklid, Parmidin.
 - C. Papaverin, Platyphyllin.
 - D. Nicotine acid.
 - E. Miscleronum, Lypoic acid.
1387. To the direct anticoagulants belongs:
- A. *Heparin.
 - B. Fenilin, Omephin.
 - C. Nicotine acid.
 - D. Streptokinase.
 - E. Aspirin.
1388. Saphenectomy is performed for:
- A. *Varicosity
 - B. Thrombosis of deep veins
 - C. Lymphedema
 - D. Obliterative atherosclerosis
 - E. Obliterative thrombangiitis
1389. Troyanov-Trendelenburg's operation is performed for:
- A. *Varicosity
 - B. Thrombosis of deep veins
 - C. Lymphedema
 - D. Obliterative atherosclerosis
 - E. Obliterative thrombangiitis
1390. The operation crossectomy is performed for:
- A. *Varicosity
 - B. Thrombosis of deep veins
 - C. Lymphedema
 - D. Obliterative atherosclerosis

- E. Obliterative thrombangiitis
- 1391. Linton's operation is performed for:
 - A. *Varicosity
 - B. Thrombosis of deep veins
 - C. Lymphedema
 - D. Obliterative atherosclerosis
 - E. Obliterative thrombangiitis
- 1392. Troyanov-Trendelenburg's operation is:
 - A. *Ligation of saphenofemoral junction
 - B. Removal of the main trunk of great saphenous vein
 - C. Suprafascial ligation of perforative veins
 - D. Subfascial ligation of perforative veins
 - E. Removal of collaterals of great saphenous vein
- 1393. Narath's operation is:
 - A. *Removal of collaterals of great saphenous vein
 - B. Ligation of saphenofemoral junction
 - C. Removal of the main trunk of great saphenous vein
 - D. Suprafascial ligation of perforative veins
 - E. Subfascial ligation of perforative veins
- 1394. Bebbcock's operation is:
 - A. *Removal of the main trunk of great saphenous vein
 - B. Removal of collaterals of great saphenous vein
 - C. Ligation of saphenofemoral junction
 - D. Suprafascial ligation of perforative veins
 - E. Subfascial ligation of perforative veins
- 1395. Cocketh's operation is:
 - A. *Suprafascial ligation of perforative veins
 - B. Removal of collaterals of great saphenous vein
 - C. Ligation of saphenofemoral junction
 - D. Removal of the main trunk of great saphenous vein
 - E. Subfascial ligation of perforative veins
- 1396. Linton's operation is:
 - A. *Subfascial ligation of perforative veins
 - B. Removal of collaterals of great saphenous vein
 - C. Ligation of saphenofemoral junction
 - D. Removal of the main trunk of great saphenous vein
 - E. Suprafascial ligation of perforative veins
- 1397. The Narath's operation is performed for:
 - A. *Varicosity
 - B. Thrombosis of deep veins
 - C. Lymphedema
 - D. Obliterative atherosclerosis
 - E. Obliterative thrombangiitis
- 1398. The Bebbcock's operation is performed for:
 - A. *Varicosity
 - B. Thrombosis of deep veins
 - C. Lymphedema
 - D. Obliterative atherosclerosis
 - E. Obliterative thrombangiitis
- 1399. The Cocketh's operation is performed for:
 - A. *Varicosity
 - B. Thrombosis of deep veins
 - C. Lymphedema
 - D. Obliterative atherosclerosis

- E. Obliterative thrombangiitis
1400. The indication for the sclerotherapy is:
- A. *Reticular varicosity
 - B. Obliterative atherosclerosis
 - C. Thrombangiitis obliterans
 - D. Thrombosis of deep veins
 - E. Lymphedema of the extremity
1401. The indication for the sclerotherapy is:
- A. *Teleangiectasy
 - B. Obliterative atherosclerosis
 - C. Thrombangiitis obliterans
 - D. Thrombosis of deep veins
 - E. Lymphedema of the extremity
1402. The indication for the sclerotherapy is:
- A. *Relapse of varicosity
 - B. Obliterative atherosclerosis
 - C. Thrombangiitis obliterans
 - D. Thrombosis of deep veins
 - E. Lymphedema of the extremity
1403. The method of choice of the treatment of reticular varicosity is:
- A. *Sclerotherapy
 - B. Linton's operation
 - C. Saphenectomy
 - D. Endarterectomy
 - E. Autovenous by-passing
1404. The method of choice of the treatment of teleangiectasy is:
- A. *Sclerotherapy
 - B. Linton's operation
 - C. Saphenectomy
 - D. Endarterectomy
 - E. Autovenous by-passing
1405. The method of choice of the treatment of relapse of varicosity is:
- A. *Sclerotherapy
 - B. Linton's operation
 - C. Saphenectomy
 - D. Endarterectomy
 - E. Autovenous by-passing
1406. For the sclerotherapy used:
- A. *Fibro vein
 - B. Triumbrast
 - C. Verographin
 - D. Barium sulfate
 - E. Bilignost
1407. After saphenectomy the elastic compression is used for:
- A. *2-3 months
 - B. 3 days
 - C. 7 days
 - D. 2 weeks
 - E. 3-4 weeks
1408. For the treatment of the varicosity of the I degree the elastic stocks and bandages are used of the:
- A. *I degree of compression
 - B. II degree of compression
 - C. III degree of compression

- D. IV degree of compression
 - E. The compression stocks are not used
1409. For the treatment of varicosity of II degree the elastic stocks and bandages are used of the:
- A. *II degree of compression
 - B. I degree of compression
 - C. III degree of compression
 - D. IV degree of compression
 - E. The compression stocks are not used
1410. After saphenectomy the elastic stocks and bandages are used of the:
- A. *II degree of compression
 - B. I degree of compression
 - C. III degree of compression
 - D. IV degree of compression
 - E. The compression stocks are not used
1411. In patients with a trophic ulcer the elastic stocks and bandages are used of the:
- A. *III degree of compression
 - B. II degree of compression
 - C. I degree of compression
 - D. IV degree of compression
 - E. The compression stocks are not used
1412. Endotelon is used for the treatment of:
- A. *Varicosity
 - B. Ulcerous disease
 - C. Uterine bleeding
 - D. Atherosclerosis obliterans
 - E. Hypertensive disease
1413. Detralelex is used for the treatment of:
- A. *Varicosity
 - B. Ulcerous disease
 - C. Uterine bleeding
 - D. Atherosclerosis obliterans
 - E. Hypertensive disease
1414. Flebodia is used for the treatment of:
- A. *Varicosity
 - B. Ulcerous disease
 - C. Uterine bleeding
 - D. Atherosclerosis obliterans
 - E. Hypertensive disease
1415. Troksevasin is used for the treatment of:
- A. *Varicosity
 - B. Ulcerous disease
 - C. Uterine bleeding
 - D. Atherosclerosis obliterans
 - E. Hypertensive disease
1416. Why the saphenectomy does always begins with the ligation of saphenofemoral junction?
- A. *To prevent pulmonary embolism
 - B. To prevent bleeding
 - C. To prevent saphenofemoral reflux
 - D. To insert easy a venous extractor
 - E. To perform the sclerotherapy
1417. What is the basic sign of subcutaneous thrombophlebitis?
- A. *Painful cord along a great saphenous vein
 - B. Trophic ulcer
 - C. A gangrene of toes

- D. Absence of pulsation
 - E. Edema of the lower extremity
1418. Painful cord along a great saphenous vein is characteristic for:
- A. *Subcutaneous thrombophlebitis
 - B. Lymphedema
 - C. Atherosclerosis obliterans
 - D. Thrombangiitis obliterans
 - E. Thrombosis of deep veins
1419. Hyperemia and infiltrate along a great saphenous vein is characteristic for:
- A. *Subcutaneous thrombophlebitis
 - B. Lymphedema
 - C. Atherosclerosis obliterans
 - D. Thrombangiitis obliterans
 - E. Thrombosis of deep veins
1420. What are the clinical manifestations of subcutaneous thrombophlebitis?
- A. *Painful infiltrate and hyperemia along a great saphenous vein
 - B. Pale cold extremity, pulsation is absent
 - C. The hot cyanotic edematous lower extremity
 - D. The pale edematous lower extremity
 - E. Gangrene of toes and trophic ulcer
1421. What is the main danger of subcutaneous thrombophlebitis?
- A. *Pulmonary embolism
 - B. Venous insufficiency
 - C. Trophic ulcer
 - D. A gangrene of toes
 - E. Paralysis
1422. To the pulmonary embolism can lead:
- A. *Subcutaneous thrombophlebitis
 - B. Lymphedema
 - C. Obliterative atherosclerosis
 - D. Obliterative thrombangiitis
 - E. Raynaud's phenomenon
1423. Development of edema of the extremity in the case of subcutaneous thrombophlebitis specifies on:
- A. *Lesion of deep veins
 - B. Infection
 - C. Cardiac insufficiency
 - D. Kidney insufficiency
 - E. Development of lymphostasis
1424. What is the typical treatment of subcutaneous thrombophlebitis?
- A. *Surgical treatment
 - B. Anticoagulants
 - C. Thrombolytics
 - D. Spasmolytics
 - E. Vitamins
1425. What is the main cause of the development of subcutaneous thrombophlebitis?
- A. *Varicosity
 - B. Arterio-venous fistulas
 - C. Venous hypoplasia
 - D. Diabetes mellitus
 - E. Obliterative atherosclerosis
1426. What is the background of the development of subcutaneous thrombophlebitis?
- A. *Inflammatory reaction of venous wall
 - B. Atherosclerotic plaque

- C. Diabetic angiopathy
 - D. Lipidemia
 - E. Anemia
1427. What factor contributes to the development of subcutaneous thrombophlebitis?
- A. *Trauma
 - B. Diabetes mellitus
 - C. Obliterative atherosclerosis
 - D. Anemia
 - E. Hemophilia
1428. What medicinal medicines can result in formation of subcutaneous thrombophlebitis?
- A. *Contraceptives
 - B. Anticoagulants
 - C. Fibrinolytics
 - D. Antiaggregants
 - E. Nonsteroid anti-inflammatory medicines
1429. Mondor's disease is:
- A. *Venous thrombosis of front chest wall
 - B. Ileofofemoral venous thrombosis
 - C. Thrombosis of subclavian vein
 - D. Thrombosis of vena cava inferior
 - E. Thrombosis of vena cava superior
1430. Venous thrombosis of front chest wall is:
- A. *Mondor's disease
 - B. Paget-Shretter's syndrome
 - C. Badda-Chiari's syndrome
 - D. Raynaud's phenomenon
 - E. Disease of Madelung
1431. A subcutaneous thrombophlebitis often associated with the following disease:
- A. *Obliterative thromboangitis
 - B. Diabetes mellitus
 - C. Obliterative atherosclerosis
 - D. Nonspecific aorto-arteriitis
 - E. Hemophilia
1432. A subcutaneous thrombophlebitis often associated with the following disease:
- A. *Varicosity
 - B. Diabetes mellitus
 - C. Obliterative atherosclerosis
 - D. Nonspecific aorto-arteriitis
 - E. Hemophilia
1433. What is the typical treatment of subcutaneous thrombophlebitis?
- A. *Surgical treatment
 - B. Anticoagulants
 - C. Thrombolytics
 - D. Spasmolytics
 - E. Vitamins
1434. What operation is performed for a subcutaneous thrombophlebitis?
- A. *Saphenectomy
 - B. Trombintimectomy
 - C. Autovenous by-passing
 - D. Prosthetic graft repairing of vessel
 - E. Amputation
1435. Saphenectomy is performed for:
- A. *Subcutaneous thrombophlebitis
 - B. Thrombosis of deep veins

- C. Lymphedema
 - D. Obliterative atherosclerosis
 - E. Obliterative thrombangiitis
1436. Troyanov-Trendelenburg's operation is performed for:
- A. *Subcutaneous thrombophlebitis
 - B. Thrombosis of deep veins
 - C. Lymphedema
 - D. Obliterative atherosclerosis
 - E. Obliterative thrombangiitis
1437. The operation crosssectomy is performed for:
- A. *Subcutaneous thrombophlebitis
 - B. Thrombosis of deep veins
 - C. Lymphedema
 - D. Obliterative atherosclerosis
 - E. Obliterative thrombangiitis
1438. What are the indications for an urgent operation?
- A. *Acute ascending thrombophlebitis
 - B. Subcutaneous thrombophlebitis of shin
 - C. Deep venous thrombosis of shin
 - D. Paget-Shretter's syndrome
 - E. Badda-Chiari's syndrome
1439. A testimony for an urgent saphenectomy is:
- A. *Acute ascending thrombophlebitis
 - B. Subcutaneous thrombophlebitis of shin
 - C. Deep venous thrombosis of shin
 - D. Paget-Shretter's syndrome
 - E. Badda-Chiari's syndrome
1440. What is the acute ascending thrombophlebitis?
- A. *Localization of blood clot in saphenofemoral junction
 - B. Total thrombotic lesion of vein
 - C. Partial thrombotic lesion of vein
 - D. Localization of blood clot in a subclavian vein
 - E. Localization of blood clot in the veins of front chest wall
1441. What is the main cause of the development of thrombosis of deep veins?
- A. *Subcutaneous thrombophlebitis
 - B. Varicosity
 - C. Arterio-venous fistulas
 - D. Diabetes mellitus
 - E. Obliterative atherosclerosis
1442. What factor contributes to the development of thrombosis of deep veins?
- A. *Operating trauma
 - B. Diabetes mellitus
 - C. Obliterative atherosclerosis
 - D. Anemia
 - E. Hemophilia
1443. What factor contributes to the development of thrombosis of deep veins?
- A. *Trauma
 - B. Diabetes mellitus
 - C. Obliterative atherosclerosis
 - D. Anemia
 - E. Hemophilia
1444. Localization of blood clot in saphenofemoral junction is:
- A. *Acute ascending thrombophlebitis
 - B. Ileo-femoral venous thrombosis

- C. Thrombosis of deep veins
 - D. Paget-Shretter's syndrome
 - E. Badda-Chiari's syndrome
1445. What are the clinical manifestations of deep venous thrombosis of shin?
- A. *Edema of shins with cyanosis
 - B. A total edema of the lower extremity with cyanosis
 - C. Edema of both lower extremities
 - D. Pale lower extremity, pulsation is absent
 - E. Varicosity of shin with a trophic ulcer
1446. What is the main danger of subcutaneous thrombophlebitis?
- A. *Pulmonary embolism
 - B. Venous insufficiency
 - C. Trophic ulcer
 - D. A gangrene of toes
 - E. Paralysis
1447. The Homan's sign is typical for:
- A. *Thrombosis of deep veins
 - B. Subcutaneous thrombophlebitis
 - C. Varicosity
 - D. Obliterative atherosclerosis
 - E. Diabetes mellitus
1448. Homan's sign is:
- A. *Pain in the muscles of shin, which increases by back flexing of foot
 - B. Intermittent claudication at physical exertion
 - C. Absence of pulsation in a cold environment
 - D. Symptom of caught shoe
 - E. Absence of hepatic dullness
1449. How is the symptom named by author, when back flexing of foot increases the pain in the muscles of shin?
- A. *Homan's sign
 - B. Lovenberg's sign
 - C. Mondor's sign
 - D. Murphy's sign
 - E. Paget-Shretter's syndrome
1450. The Lovenberg's sign is typical for:
- A. *Thrombosis of deep veins
 - B. Obliterative atherosclerosis
 - C. Diabetes mellitus
 - D. Subcutaneous thrombophlebitis
 - E. Varicosity
1451. Lovenberg's sign is:
- A. *Pain in the muscles of shin after imposition of cuff with pressure 80-100 mm of Hg.
 - B. Intermittent claudication at physical exertion
 - C. Absence of pulsation in a cold environment
 - D. Absence of hepatic dullness
 - E. Pain in the muscles of shin, caused by the back flexing of foot
1452. What are the clinical manifestations of ileofemoral venous thrombosis?
- A. *A total edema of the lower extremity with cyanosis
 - B. Edema of shins with cyanosis
 - C. Edema of both lower extremities
 - D. Pale lower extremity, pulsation is absent
 - E. Varicosity of shin with a trophic ulcer
1453. Intermittent claudication is characteristic for:
- A. *Atherosclerosis of lower extremities

- B. Thrombosis of deep veins
 - C. Pancreatitis
 - D. Varicosity
 - E. Cholecystitis
1454. Dilating pain in extremity is characteristic for:
- A. *Thrombosis of deep veins
 - B. Teleangiektaziy
 - C. Retikulyarnogo varicosity
 - D. Mikotichnogo of lesion
 - E. Diseasees of Madelunga
1455. Edema of the extremity is characteristic for:
- A. *Thrombosis of deep veins
 - B. Teleangiectasia
 - C. Reticular varicosity
 - D. Mycotic lesion
 - E. Madelung's disease
1456. Cyanosis of the skin of extremity is characteristic for:
- A. *Thrombosis of deep veins
 - B. Teleangiectasia
 - C. Reticular varicosity
 - D. Mycotic lesion
 - E. Madelung's disease
1457. Intermittent claudication is characteristic for:
- A. *Atherosclerosis obliterans
 - B. Thrombosis of deep veins
 - C. Teleangiectasia
 - D. Reticular varicosity
 - E. Madelung's disease
1458. In thrombosis of deep veins the patients complain on:
- A. *Dilating pain in extremity
 - B. Intermittent claudication
 - C. Coldness of the extremity
 - D. Varicosity
 - E. Presence of trophic ulcer
1459. In thrombosis of deep veins the patients complain on:
- A. *Edema of extremities
 - B. Intermittent claudication
 - C. Coldness of the extremity
 - D. Poblidninnya of the extremity
 - E. Presence of trophic ulcer
1460. In thrombosis of deep veins the patients complain on:
- A. *Cyanosis of the skin of the extremity
 - B. Intermittent claudication
 - C. Coldness of the extremity
 - D. Pale extremity
 - E. Presence of trophic ulcer
1461. What is the classic clinical triad for a deep venous thrombosis?
- A. *Pain, edema, cyanosis of the extremity
 - B. Pale lower extremity, absent pulsation, edema
 - C. The varicosity of the lower extremity, trophic ulcer, edema
 - D. Pain, paralysis, cyanosis
 - E. Pain, paralysis, trophic ulcer
1462. What is the characteristic clinical sign of deep venous thrombosis?
- A. *Edema of extremities

- B. Pulsation is absent
 - C. Trophic ulcer
 - D. Paralysis
 - E. Gangrene
1463. What are the basic collaterals for compensation of venous outflow in thrombosis of distal segment of vena cava inferior?
- A. *Azygos and hemiazygos veins
 - B. Lumbar veins
 - C. Femoral veins
 - D. Kidney veins
 - E. Vena cava superior
1464. What are the clinical manifestations of thrombosis of distal segment of vena cava inferior?
- A. *Edema of lower half of body and lower extremities
 - B. Trophic ulcers of lower extremities
 - C. Gangrene of lower extremities
 - D. Kidney insufficiency
 - E. Insufficiency of liver
1465. Edema of lower extremities is characteristic for:
- A. *Thrombosis of vena cava inferior
 - B. Leriche's syndrome
 - C. Aortic aneurysm
 - D. Paget-Shretter's syndrome
 - E. Thrombosis of vena cava superior
1466. Disturbance of sensation is characteristic for:
- A. *Embolisms of the artery
 - B. Varicosity
 - C. Thrombosis of deep veins
 - D. Subcutaneous thrombophlebitis
 - E. Lymphedema
1467. Paresis of the extremity is characteristic for:
- A. *Arterial thrombosis
 - B. Varicosity
 - C. Thrombosis of deep veins
 - D. Subcutaneous thrombophlebitis
 - E. Lymphedema
1468. Plegia of the extremity is characteristic for:
- A. *Embolisms of the artery
 - B. Varicosity
 - C. Thrombosis of deep veins
 - D. Subcutaneous thrombophlebitis
 - E. Lymphedema
1469. Absence of pulsation on extremity is characteristic for:
- A. *Embolisms of the artery
 - B. Varicosity
 - C. Thrombosis of deep veins
 - D. Subcutaneous thrombophlebitis
 - E. Postphlebitic syndrome
1470. Muscular contracture of the extremity is characteristic for:
- A. *Embolisms of the artery
 - B. Varicosity
 - C. Thrombosis of deep veins
 - D. Subcutaneous thrombophlebitis
 - E. Postphlebitic syndrome
1471. Development of kidney insufficiency is characteristic for:

- A. *Thrombosis of renal segment of vena cava inferior
 - B. Thrombosis of distal segment of vena cava inferior
 - C. Thrombosis of hepatic segment of vena cava inferior
 - D. Paget-Shretter's syndrome
 - E. Thrombosis of vena cava superior
1472. Development of Badda-Chiari's syndrome is characteristic for:
- A. *Thrombosis of hepatic segment of vena cava inferior
 - B. Thrombosis of renal segment of vena cava inferior
 - C. Thrombosis of distal segment of vena cava inferior
 - D. Paget-Shretter's syndrome
 - E. Thrombosis of vena cava superior
1473. What are the clinical manifestations of thrombosis of kidney segment of vena cava inferior?
- A. *Kidney insufficiency
 - B. Trophic ulcers of lower extremities
 - C. Edema of lower half of body and lower extremities
 - D. Gangrene of lower extremities
 - E. Insufficiency of liver
1474. What are the clinical manifestations of thrombosis the hepatic segment of vena cava inferior?
- A. *Badda-Chiari's syndrome
 - B. Trophic ulcers of lower extremities
 - C. Edema of lower half of body and lower extremities
 - D. Gangrene of lower extremities
 - E. Kidney insufficiency
1475. Badda-Chiari's syndrome is:
- A. *Thrombosis of hepatic veins
 - B. Ileo-femoral venous thrombosis
 - C. Thrombosis of subclavian vein
 - D. Thrombosis of kidney veins
 - E. Thrombosis of vein of gate
1476. What are the clinical manifestations of Badda-Chiari's syndrome?
- A. *Portal hypertension
 - B. Trophic ulcer of lower extremities
 - C. Respiratory insufficiency
 - D. Gangrene of lower extremities
 - E. Hematuria
1477. Thrombosis of axillary and subclavian vein is:
- A. *Paget-Shretter's syndrome
 - B. Badda-Chiari's syndrome
 - C. Cushing's syndrome
 - D. Leriche's syndrome
 - E. Syndrome of Morgani-Adams-Stokes
1478. Paget-Shretter's syndrome is:
- A. *Thrombosis of axillary and subclavian vein
 - B. Occlusion of bifurcation of aorta
 - C. Thrombosis of vena cava superior
 - D. Thrombosis of hepatic veins
 - E. Thrombosis of vena cava inferior
1479. In Paget-Shretter's syndrome the patients complain on:
- A. *Edema of upper extremity
 - B. Intermittent claudication
 - C. Coldness of the extremity
 - D. Pale extremity
 - E. Presence of trophic ulcer

1480. In Paget-Shretter's syndrome the patients complain on:
- A. *Edema of upper extremity
 - B. Edema of the lower extremity
 - C. Edema of both lower extremities
 - D. Edema of lower half of body
 - E. Pulsation of neck veins
1481. In Paget-Shretter's syndrome the patients complain on:
- A. *Cyanosis of upper extremity
 - B. Cyanosis of the lower extremity
 - C. Varicose veins of the lower extremity
 - D. Cyanosis of lower half of body
 - E. Varicose veins of front abdominal wall
1482. What is the main cause of Paget-Shretter's syndrome?
- A. *Compression of subclavian vein in costo-clavicular space
 - B. Compression of common iliac vein by a tumour
 - C. Atherosclerotic lesion of arteries of upper extremities
 - D. Atherosclerotic lesion of carotid
 - E. Aortic aneurysm
1483. Compression of subclavian vein is a risk factor for:
- A. *Paget-Shretter's syndrome
 - B. Badda-Chiari's syndrome
 - C. Cushing's syndrome
 - D. Leriche's syndrome
 - E. Morgani-Adams-Stokes syndrome
1484. Implantation of pace-maker is a risk factor for:
- A. *Paget-Shretter's syndrome
 - B. Badda-Chiari's syndrome
 - C. Cushing's syndrome
 - D. Leriche's syndrome
 - E. Morgani-Adams-Stokes syndrome
1485. The mastectomy operation is a risk factor for:
- A. *Paget-Shretter's syndrome
 - B. Badda-Chiari's syndrome
 - C. Cushing's syndrome
 - D. Leriche's syndrome
 - E. Morgani-Adams-Stokes syndrome
1486. What are the clinical manifestations of Paget-Shretter's syndrome?
- A. *Edema of upper extremity with cyanosis
 - B. A pale hand, pulsation is absent
 - C. Pale lower extremity, pulsation is absent
 - D. Varicosity of the lower extremity with a trophic ulcer
 - E. Edema of both lower extremities with cyanosis
1487. What is the main cause of the syndrome of vena cava superior?
- A. *Tumour of mediastinum
 - B. Subcutaneous thrombophlebitis
 - C. Deep venous thrombosis of lower extremities
 - D. Tumour of retroperitoneal space
 - E. Tumour of abdominal region
1488. What are the clinical manifestations of the syndrome of vena cava superior?
- A. *Edema of upper half of body and hands with cyanosis
 - B. Trophic ulcer of upper extremities
 - C. Edema of lower half of body and lower extremities with cyanosis
 - D. Absence of pulsation of carotids
 - E. Absence of pulsation of arteries of upper extremities

1489. What is the level of the absent pulsation in thrombosis of deep veins?
- A. *Preserved on all levels
 - B. Tibial arteries
 - C. Popliteal artery
 - D. Femoral artery
 - E. Aorta
1490. Which among the roentgenologic methods of diagnostics is the most informative for thrombosis of deep veins?
- A. *Phlebography
 - B. Arteriography
 - C. X-ray examination of abdomen
 - D. X-ray examination with barium
 - E. X-ray examination of the extremity
1491. Which among the methods of diagnostics is the most informative for thrombosis of deep veins?
- A. *Ultrasound examination
 - B. Arteriography
 - C. X-ray examination of abdomen
 - D. X-ray examination of chest
 - E. X-ray examination of the extremity
1492. What method is used for the diagnostics of thrombosis of deep veins?
- A. *Ultrasound duplex scanning
 - B. Coagulogram
 - C. Reovasography
 - D. Ultrasound Doppler examination
 - E. Arteriography
1493. What are the indications for endarterectomy:
- A. *Obliterative atherosclerosis
 - B. Subcutaneous thrombophlebitis
 - C. Leriche's syndrome
 - D. Thrombosis of deep veins
 - E. Varicosity
1494. What group of medicinal drugs the heparin belongs to?
- A. *Direct anticoagulants
 - B. Indirect anticoagulants
 - C. Thrombolytics
 - D. Fibrinolytics
 - E. Antiinflammatory drugs
1495. What group of medicinal drugs the Klexan belongs to?
- A. *Direct anticoagulants
 - B. Indirect anticoagulants
 - C. Thrombolytics
 - D. Fibrinolytics
 - E. Antiinflammatory drugs
1496. What group of medicinal drugs the Sincumar belongs to?
- A. *Indirect anticoagulants
 - B. Direct anticoagulants
 - C. Thrombolytics
 - D. Fibrinolytics
 - E. Antiinflammatory drugs
1497. What group of medicinal drugs the Fenillin belongs to?
- A. *Indirect anticoagulants
 - B. Direct anticoagulants
 - C. Thrombolytics

- D. Fibrinolytics
 - E. Antiinflammatory drugs
1498. What group of medicinal drugs the Actilise belongs to?
- A. *Thrombolytics
 - B. Indirect anticoagulants
 - C. Direct anticoagulants
 - D. Venotonics
 - E. Antiinflammatory drugs
1499. What group of medicinal drugs the Streptokinase belongs to?
- A. *Thrombolytics
 - B. Indirect anticoagulants
 - C. Direct anticoagulants
 - D. Venotonics
 - E. Antiinflammatory drugs
1500. What group of medicinal drugs the Detralex belongs to?
- A. *Venotonics
 - B. Thrombolytics
 - C. Indirect anticoagulants
 - D. Direct anticoagulants
 - E. Antiinflammatory drugs
1501. What group of medicinal drugs the Venoplant belongs to?
- A. *Venotonics
 - B. Thrombolytics
 - C. Indirect anticoagulants
 - D. Direct anticoagulants
 - E. Antiinflammatory drugs
1502. What medical drugs belong to the direct anticoagulants?
- A. *Heparin
 - B. Syncumarum, Fenilin
 - C. Streptokinase, Urokinase
 - D. Trentalum, Pentoxiphyllin
 - E. Diklofenak, Naklofen
1503. What medical drugs belong to the direct anticoagulants?
- A. *Fraxiparin, Kleksan
 - B. Syncumarum, Fenilin
 - C. Streptokinase, Urokinase
 - D. Trentalum, Pentoxiphyllin
 - E. Diklofenak, Naklofen
1504. What medical drugs belong to the indirect anticoagulants?
- A. *Syncumarum, Fenilin
 - B. Fraxiparin, Kleksan
 - C. Streptokinase, Urokinase
 - D. Trentalum, Pentoxiphyllin
 - E. Diklofenak, Naklofen
1505. What medical drugs belong to fibrinolytics?
- A. *Streptokinase, Urokinase
 - B. Heparin
 - C. Syncumarum, Fenilin
 - D. Trentalum, Pentoxiphyllin
 - E. Diklofenak, Naklofen
1506. What is the dose of heparin for the treatment of thrombophlebitis?
- A. *5000-10000 Units each 4-6 hours
 - B. 1000-2000 Units each 4-6 hours
 - C. 1000-2000 Units daily

- D. 2500 Units every hour
 - E. 20000-40000 Units each 12 hours
1507. What is the initial dose of Streptokinase?
- A. *250000 Units
 - B. 5000 Units
 - C. 10000 Units
 - D. 100000 Units
 - E. 1000000 Units
1508. What drugs are used in the overdose of heparin?
- A. *Protamine sulfate
 - B. Fraxiparin, Kleksan
 - C. Streptokinase, Urokinase
 - D. Trentalum, Pentoxiphyllin
 - E. Diklofenak, Naklofen
1509. What drugs are used in the overdose of Streptokinase?
- A. *Aminocapronic acid, Trasyololum
 - B. Fraxiparin, Kleksan
 - C. Protamine sulfate
 - D. Trentalum, Pentoxiphyllin
 - E. Diklofenak, Naklofen
1510. What medical drugs belong to venotonics?
- A. *Detralex, Flebodia
 - B. Heparin
 - C. Syncumarum, Fenilin
 - D. Papaverin, Nospanum
 - E. Diklofenak, Naklofen
1511. What are the normal measures of prothrombine index?
- A. *85-100 %
 - B. 10-20 %
 - C. 30-60 %
 - D. 50-70 %
 - E. 100-120 %
1512. What prothrombine index must be during the treatment of venous thrombosis?
- A. *50-70 %
 - B. 10-20 %
 - C. 30-40 %
 - D. 85-100 %
 - E. 100-120 %
1513. What indexes of coagulogram control the dosage of anticoagulants?
- A. *Prothrombine index
 - B. The amount of thrombocytes in the blood
 - C. Level of blood fibrinogen
 - D. Thrombotest
 - E. Time of recalcification
1514. What is the normal level of blood fibrinogen?
- A. *2-4 g/l
 - B. 6-8 g/l
 - C. 10-16 g/l
 - D. 30-50 g/l
 - E. 75-100 g/l
1515. What indexes of coagulogram control the dosage of thrombolytics?
- A. *Level of blood fibrinogen
 - B. The amount of thrombocytes in the blood
 - C. Prothrombine index

- D. Thrombotest
- E. Time of recalcification
- 1516. What is the norm of time of recalcification?
 - A. *60-120 seconds
 - B. 0.5-2 seconds
 - C. 10-40 seconds
 - D. 40-60 seconds
 - E. 4-8 minutes
- 1517. What are the normal measures of the thrombotest?
 - A. *IV-V degree
 - B. I-II degree
 - C. II-III degree
 - D. VI-VIII degree
 - E. X-XII degree
- 1518. What is the normal amount of thrombocytes in blood?
 - A. *180-320?10⁹/l
 - B. 20-40?10⁹/l
 - C. 40-120?10⁹/l
 - D. 420-650?10⁹/l
 - E. 600-1000?10⁹/l
- 1519. What method is used for the diagnostics of deep venous thrombosis?
 - A. *Ultrasound doppler examination
 - B. General and biochemical analyses of blood
 - C. Coagulogram
 - D. Reovasography
 - E. Arteriography
- 1520. What treatment is used for the deep venous thrombosis of shin?
 - A. *Conservative treatment
 - B. Thrombectomy
 - C. Saphenectomy
 - D. Autovenous by-passing
 - E. Prosthetic graft repairing of vessel
- 1521. What treatment is used for ileofemoral venous thrombosis?
 - A. *Conservative treatment
 - B. Saphenectomy
 - C. Thrombectomy
 - D. Autovenous by-passing
 - E. Prosthetic graft repairing of vessel
- 1522. Iliofemoral prosthetic by-passing is performed for:
 - A. *Obliterative atherosclerosis
 - B. Postphlebotic syndrome
 - C. Varicosity
 - D. Thrombosis of deep veins
 - E. Subcutaneous thrombophlebitis
- 1523. Femoro-popliteal autovenous by-passing is performed for:
 - A. *Obliterative atherosclerosis
 - B. Postphlebotic syndrome
 - C. Varicosity
 - D. Thrombosis of deep veins
 - E. Subcutaneous thrombophlebitis
- 1524. Bifurcation aorto-femoral prosthetic by-passing is performed for:
 - A. *Obliterative atherosclerosis
 - B. Postphlebotic syndrome
 - C. Varicosity

- D. Thrombosis of deep veins
 - E. Subcutaneous thrombophlebitis
1525. Decompression osteoperforation is performed for:
- A. *Obliterative atherosclerosis
 - B. Postphlebitic syndrome
 - C. Varicosity
 - D. Thrombosis of deep veins
 - E. Subcutaneous thrombophlebitis
1526. A sympathectomy is performed for:
- A. *Obliterative thrombangiitis
 - B. Obliterative atherosclerosis
 - C. Varicosity
 - D. Thrombosis of deep veins
 - E. Subcutaneous thrombophlebitis
1527. When is the operation possible in ileofemoral venous thrombosis?
- A. *Duration of disease less than 5 days
 - B. Duration of disease 7-14 days
 - C. Duration of disease 21-28 days
 - D. Duration of disease of 2-3 months
 - E. In a "cold" period
1528. What is the level of arterial pulsation absence in the thrombosis of deep veins?
- A. *Preserved on all levels
 - B. Arteries of foot
 - C. Femoral artery
 - D. Popliteal artery
 - E. Common carotid
1529. What method of prophylaxis of pulmonary embolism is used during the operation for ileofemoral venous thrombosis?
- A. *Introduction of ballon catheter to the vena cava inferior during the operation
 - B. The elastic bandage during the operation
 - C. Application of anticoagulants during the operation
 - D. Application of fibrinolytics during the operation
 - E. Introduction of ballon catheter to the vena cava superior during the operation
1530. What method of prophylaxis of pulmonary embolism is used during the operation for ileofemoral venous thrombosis?
- A. *Introduction of cava-filters to the vena cava inferior during the operation
 - B. Application of anticoagulants during the operation
 - C. Application of fibrinolytics during the operation
 - D. The elastic bandage during the operation
 - E. Introduction of ballon catheter to the vena cava superior during the operation
1531. When after a deep venous thrombosis do we make the diagnosis of postphlebitic syndrome?
- A. *In 6 months
 - B. In 10-14 days
 - C. In 1 month
 - D. Through 2 months
 - E. In 1 year
1532. What are the clinical manifestations of postphlebitic syndrome?
- A. *The expressed edema, secondary varicosity
 - B. Subcutaneous thrombophlebitis
 - C. Arterial ischemia
 - D. Contracture of joints
 - E. Paralysis
1533. What is the cause of postphlebitic syndrome?
- A. *Thrombosis of deep veins

- B. Arterial embolism
 - C. Arterial thrombosis
 - D. Subcutaneous thrombophlebitis
 - E. Varicosity
1534. The pallor of the skin is characteristic for:
- A. *Embolisms of the artery
 - B. Varicosity
 - C. Deep vein thrombosis
 - D. Postphlebitic syndrome
 - E. Phlegmon of the extremity
1535. A coldness of the extremity is characteristic for:
- A. *Arterial thrombosis
 - B. Varicosity
 - C. Deep vein thrombosis
 - D. Postphlebitic syndrome
 - E. Phlegmon of the extremity
1536. What is the base of postphlebitic syndrome?
- A. *Valvular incompetence
 - B. Venous occlusion
 - C. Arterial occlusion
 - D. Nervous damage
 - E. Gangrene of the extremity
1537. What clinical form of postphlebitic syndrome does not exist?
- A. *Gangrenous
 - B. Sclerotic
 - C. Varicose
 - D. Edematous
 - E. Ulcerous
1538. What is the typical follow up of deep venous thrombosis?
- A. *Recanalization of blood clot with valvular incompetence
 - B. Complete obliteration of vein
 - C. Partial obliteration of vein
 - D. Varicose expansion
 - E. Arterio-venous fistula
1539. What are the clinical manifestations of postphlebitic syndrome?
- A. *Signs of venous insufficiency
 - B. Signs of nervous damage
 - C. Signs of vascular dystonia
 - D. Signs of arterial insufficiency
 - E. Limitation of movements of the lower extremity
1540. What medicines belong to thrombolytic medicines?
- A. *Fibrinolysin, Streptokinase.
 - B. Nicotine acid.
 - C. Papaverin, Platyphyllin.
 - D. Fenilin, Omefin.
 - E. Vasaprostan
1541. What clinical sign is characteristic for a postphlebitic syndrome?
- A. *Edema of leg
 - B. Absence of pulsation
 - C. Paralysis
 - D. Gangrene
 - E. Absence of sensation
1542. What is the characteristic sign of the I stage of postphlebitic syndrome?
- A. *Transitory edema

- B. Permanent edema
 - C. Hyperpigmentation
 - D. Trophic ulcer
 - E. Gangrene
1543. What is the characteristic sign of the II stage of postphlebitic syndrome?
- A. *Hyperpigmentation
 - B. Heavy sensation
 - C. Transitory edema
 - D. Open trophic ulcer
 - E. Healed trophic ulcer
1544. What is the characteristic sign of the II stage of postphlebitic syndrome?
- A. *Permanent edema
 - B. Heavy sensation
 - C. Transitory edema
 - D. Open trophic ulcer
 - E. Healed trophic ulcer
1545. What is the characteristic sign of the III stage of postphlebitic syndrome?
- A. *Trophic ulcer
 - B. Heavy sensation
 - C. Transitory edema
 - D. Permanent edema
 - E. Hyperpigmentation
1546. What clinical form of postphlebitic syndrome is characterized by absence of varicosity?
- A. *Sclerotic
 - B. Varicose
 - C. Edematous
 - D. Ulcerous
 - E. Necrotizing
1547. What clinical form of postphlebitic syndrome is characterized by the secondary varicosity?
- A. *Varicose
 - B. Sclerotic
 - C. Edematous
 - D. Ulcerous
 - E. Necrotizing
1548. What clinical form of postphlebitic syndrome is caused by a venous obstruction?
- A. *Edematous
 - B. Sclerotic
 - C. Varicose
 - D. Ulcerous
 - E. Necrotizing
1549. What is the physiology norm of fibrinogen in the blood serum?
- A. *2.2 - 4.2 g/l.
 - B. 5.5 - 7.5 g/l.
 - C. 5.6 - 8.0 g/l.
 - D. 5.9 - 9.2 g/l.
 - E. 7.8 - 5.5 g/l.
1550. What is the physiology norm of prothrombine index?
- A. *80 - 100 %.
 - B. 40 - 60 %.
 - C. 110 - 130 %.
 - D. 15 - 45 %.
 - E. 0 - 10 %.
1551. To the absolute contraindications for the usage of anticoagulants belongs:
- A. *Bleeding of any localization, hemorrhagic diateses

- B. Aplastic anemia
 - C. Respiratory insufficiency
 - D. Cardiac insufficiency
 - E. Insufficiency of cerebral blood circulation
1552. To the activators of Fibrinolysis belong:
- A. *Nicotinic acid, Complamine
 - B. Fenilin, Omefin
 - C. Gastrocepin, Venter
 - D. Vitamins B
 - E. Vitamins A, C.
1553. Medicines of antiaggregant activity:
- A. *Reopolyglucin, Trental, aspirin, курантіл
 - B. Omefin, Fenillin, Pelentan
 - C. Cinarizin, Sermion, Solcoseril
 - D. Fentalamin, Tropaphen
 - E. Simvastatin
1554. Medicines of thrombolytic action:
- A. *Fibrinolysin, Streptokinase
 - B. Korglucon, strophanthin
 - C. Celonid, Lantozid
 - D. Reopolyglucin, polyhybrid
 - E. Trentalum, Pentoxiphyllin
1555. The embolectomy is performed for:
- A. *Embolisms of the artery
 - B. Varicosity
 - C. Thrombosis of deep veins
 - D. Postphlebotic syndrome
 - E. Phlegmon of the extremity
1556. Trombintimectiony is performed for:
- A. *Arterial thrombosis
 - B. Thrombosis of deep veins
 - C. Embolisms of the artery
 - D. Subcutaneous thrombophlebitis
 - E. Varicosity
1557. The collateral autovenous by-passing is performed for:
- A. *Arterial thrombosis
 - B. Thrombosis of deep veins
 - C. Embolisms of the artery
 - D. Subcutaneous thrombophlebitis
 - E. Varicosity
1558. Methods of control of the coagulative and fibrinolytic systems of blood:
- A. *Coagulogram
 - B. General blood analysis
 - C. Determination of speed of local blood stream
 - D. Hemogram
 - E. Biochemical blood test
1559. In the overdosing of heparin enter:
- A. *1% solution of Protamini sulfate
 - B. Cimiton, Lobeline
 - C. Amitriptilin
 - D. 2,5% solution of Aminasini
 - E. Adrenalin
1560. In bleeding, caused by the indirect anticoagulants prescribed:
- A. *Vikasol

- B. Pipolphenum
 - C. Digitoksin
 - D. Hidrokortizon
 - E. Petoksifilin
1561. In fibrinolytic bleeding prescribed:
- A. *Aminokapronovu acid
 - B. 1 % solution of Ombeni, 0,5 % solution of hydrocortison, prednisolon
 - C. 0,1 % solution of nicotine acid
 - D. 5 % solution of аскорбінової acid
 - E. AlprostThe
1562. What is the purpose of the usage of thrombolytic and anticoagulating therapy:
- A. *Lysis of blood clot, prophylaxis of distribution of blood clot
 - B. Improvement of function of liver
 - C. To development of collateral net
 - D. A removal of the spasm on peripheral vessels
 - E. Improvement of microcirculation
1563. Name the unpharmacological methods of correction of the coagulative system of blood.
- A. Hemodilution.
 - B. Hemodialysis.
 - C. Hemosorbtion.
 - D. A forced diuresis.
 - E. Lymphosorbtion.
1564. Where does a small saphenous vein drain?
- A. *In a popliteal vein.
 - B. In a great saphenous vein.
 - C. In a femoral vein.
 - D. In a general iliac vein.
 - E. In a vena cava inferior.
1565. What method is used for the diagnostics of valvular incompetence in postphlebitic syndrome?
- A. *Ultrasound duplex scanning
 - B. Coagulogram
 - C. Reovasography
 - D. Ultrasound doppler examination
 - E. Arteriography
1566. What method is used for the estimation of the passability of deep veins in postphlebitic syndrome?
- A. *Ultrasound examination
 - B. Coagulogram
 - C. Reovasography
 - D. ECG
 - E. Arteriography
1567. What treatment is indicated for a postphlebitic syndrome?
- A. *Saphenectomy
 - B. Conservative treatment
 - C. Scelerotherapy
 - D. Troyanov-Trendelenburg's operation
 - E. Saphenectomy with the subfascial ligation of perforative veins (Linton's operation)
1568. The trophic ulcer of the lower third of shin is characteristic for:
- A. *Postphlebitic syndrome
 - B. Thrombosis of deep veins
 - C. Thrombangiitis obliterans
 - D. Leriche's syndrome
 - E. Embolisms of femoral artery

1569. The basic source of emboli in pulmonary embolism is:
- A. *System of vena cava inferior
 - B. Subclavian artery
 - C. Left ventricle
 - D. Femoral artery
 - E. Abdominal part of aorta
1570. The cause of pulmonary embolism is:
- A. *Thrombosis of deep veins of lower extremities
 - B. Bacterial endocarditis
 - C. Myocardial infarction
 - D. Abdominal aortic aneurysm
 - E. Obliterative atherosclerosis of lower extremities
1571. To massive pulmonary embolism belongs:
- A. *Occlusion of basic trunk of pulmonary artery and its branches
 - B. Embolism of lobe branches of pulmonary artery
 - C. Embolism of segmental branches of pulmonary artery
 - D. Embolism of lobe branches of pulmonary artery with iliofemoral vein thrombosis
 - E. Embolism of segmental branches of pulmonary artery with subcutaneous thrombophlebitis
1572. Which among the symptoms is characteristic for pulmonary embolism?
- A. *Pain behind breastbone
 - B. Regurgitation
 - C. Intermittent claudication
 - D. Paradoxical breathing
 - E. Syndrome of thoracic outlet
1573. Which among the symptoms is characteristic for pulmonary embolism?
- A. *Dyspnoea
 - B. Regurgitation
 - C. Intermittent claudication
 - D. Paradoxical breathing
 - E. Syndrome of thoracic outlet
1574. Which among the symptoms is characteristic for pulmonary embolism?
- A. *Shock
 - B. Regurgitation
 - C. Intermittent claudication
 - D. Paradoxical breathing
 - E. Syndrome of thoracic outlet
1575. EKG change in pulmonary embolism is characterized by:
- A. *The overload of right parts of heart
 - B. The overload of left parts of heart
 - C. Heart premature beats
 - D. Atrial fibrillation
 - E. By the total block of left leg of His bundle
1576. A typical roentgenologic sign of pulmonary embolism is:
- A. *Wedge-shaped atelectasis
 - B. Rounded shadow
 - C. Pneumothorax
 - D. Caverns
 - E. "Rat tail" sign
1577. A typical roentgenologic sign of pulmonary embolism is:
- A. *Pleural effusion
 - B. Rounded shadow
 - C. Pneumothorax
 - D. Caverns

- E. "Rat tail" sign
1578. Which among roentgenologic signs is not characteristic for pulmonary embolism?
- *Rounded shade
 - Wedge-shaped atelectasis
 - Pleural effusion
 - Dilatation of right ventricle
 - High standing of diaphragm dome
1579. Which among instrumental methods is the most informative for the diagnostic of pulmonary embolism?
- *Angiopneumography
 - X-ray examination of chest
 - Ultrasound examination
 - ECG
 - EchoCG
1580. Massive pulmonary embolism is characterized by the following clinic:
- *Phenomena of shock
 - Infarction pneumonia
 - Hemoptysis
 - Pleurisy
 - Asymptomatic course
1581. Which among symptoms is not characteristic for infarction pneumonia?
- *Ring-like shade
 - Wedge-shaped atelectasis
 - Hemoptysis
 - Pleural effusion
 - Increase body t°
1582. For differentiation between pulmonary embolism and myocardial infarction is used:
- *ECG
 - Ultrasound examination
 - X-ray examination of chest
 - Fibrogastroscopy
 - Spirography
1583. Which among echocardiographic signs is not characteristic for pulmonary embolism?
- *Dilated, hypokinetic left ventricle
 - Dilated, hypokinetic right ventricle
 - Dilatation of proximal pulmonary arteries
 - The increase of bloodflow velocity of tricuspid regurgitation $>3-7$ m/s
 - Disturbance of bloodsource from a right ventricle
1584. The direct signs of pulmonary embolism on the angiopneumography are:
- *Defects of filling of vessels
 - Dilatation of pulmonary artery trunk and its large branches
 - Asymmetry of filling of vessels by a contrast substance
 - The stasis of contrast
 - Pleural effusion
1585. The direct signs of pulmonary embolism on the angiopneumography are:
- *«Amputation» of vessel with dilatation proximally to occlusion
 - Dilatation of pulmonary artery trunk and its large branches
 - Asymmetry of filling of vessels by a contrast substance
 - The stasis of contrast
 - Pleural effusion
1586. The direct signs of pulmonary embolism on the angiopneumography are:
- *Oligemia
 - Dilatation of pulmonary artery trunk and its large branches
 - Asymmetry of filling of vessels by a contrast substance

- D. The stasis of contrast
 - E. Pleural effusion
1587. To the laboratory methods which confirm the pulmonary embolism belong:
- A. *Determination of D-dimer
 - B. General blood analysis
 - C. Determination of cholinesterase activity
 - D. Determination of circulatory immune complexes
 - E. Determination of antiphospholipid factor
1588. For the control of anticoagulating therapy in pulmonary embolism used:
- A. *The partial activated thromboplastine time
 - B. Fibrinogen of blood
 - C. Thrombotest
 - D. Tolerance of blood serum to heparin
 - E. Time of recalcification
1589. The initial dose of heparin in the treatment of pulmonary embolism:
- A. *10-20 thousands Unites
 - B. 2,5-5 thousands Unites
 - C. 1-2,5 thousands Unites
 - D. 40-60 thousands Unites
 - E. 100 thousands Unites
1590. What index of the partial activated thromboplastine time, which confirms the efficiency of anticoagulating therapy?
- A. *Increase in 1,5-2 times
 - B. Does not change
 - C. Diminish in 1,5-2 times
 - D. Diminish in 3-5 times
 - E. Diminish in 10-15 times
1591. Medicine of choice of thrombolytic therapy in pulmonary embolism is:
- A. *Aktilise
 - B. Heparin
 - C. Fibrinolysin
 - D. Fraxiparin
 - E. Clexan
1592. What is the dose of Aktilise is used in the treatment of pulmonary embolism?
- A. *100 mg.
 - B. 5 mg.
 - C. 10 mg.
 - D. 500 mg.
 - E. 1000 mg.
1593. The indication for application of thrombolytic therapy is:
- A. *Pulmonary embolism
 - B. Hemorrhagic shock
 - C. Suspicion on dissection of aorta
 - D. Severe traumas or great surgical operations within 2 weeks
 - E. Septic endocarditis
1594. The indication for application of thrombolytic therapy is:
- A. *Deep vein thrombosis
 - B. Hemorrhagic shock
 - C. Suspicion on dissection of aorta
 - D. Severe traumas or great surgical operations within 2 weeks
 - E. Septic endocarditis
1595. What diseases are not contraindication for the thrombolytic therapy?
- A. *Acute myocardial infarction
 - B. Hemorrhagic shock

- C. Suspicion on dissection of aorta
 - D. Severe traumas or great surgical operations within 2 weeks
 - E. Septic endocarditis
1596. What diseases are not contraindication for thrombolytic therapy?
- A. *Acute ileofemoral venous thrombosis
 - B. Hemorrhagic shock
 - C. Suspicion on dissection of aorta
 - D. Severe traumas or great surgical operations within 2 weeks
 - E. Septic endocarditis
1597. In relapse pulmonary embolism with a prophylactic purpose used:
- A. *Implantation of cava-filters
 - B. Direct anticoagulants
 - C. Indirect anticoagulants
 - D. Thrombolytics
 - E. Profundoplastiks
1598. What operation is performed in patients with pulmonary embolism?
- A. *Thrombectomy from a pulmonary artery
 - B. Ligation of pulmonary artery
 - C. Prosthetic graft repairing of pulmonary artery
 - D. Resection of pulmonary artery
 - E. Pneumonectomy

Situational tasks

1. Complaints of cough with purulent sputum, increased body temperature to 39°C, pain in the left half of the chest. Has been ill for 2 weeks, the onset is caused by undercooling. The lag of the left half of the chest during breathing, lung sounds by percussion, by auscultation crackling rales over the lower lobe of the left lung. On X-ray of the chest expressed infiltration of lung tissue with areas of enlightenment in the center. What is the primary diagnosis?
 - A. *Abscessing pneumonia.
 - B. Pleural empyema.
 - C. Acute lung abscess.
 - D. Pyopneumothorax.
 - E. Bronchiectatic disease.
2. Complaints of cough with purulent sputum, increased body temperature to 39°C, pain in the left half of the chest. Has been ill for 2 weeks, the onset is caused by undercooling. The lag of the left half of the chest during breathing, the shortening of percussion sound over the lower lobe, by auscultation weakened breathing with amphoric sound, crackling rales. On X-ray of the chest expressed infiltration of lung tissue with enlightenment in the center with fluid level. What is the primary diagnosis?
 - A. *Acute lung abscess.
 - B. Pleural empyema.
 - C. Abscessing pneumonia.
 - D. Pyopneumothorax.
 - E. Bronchiectatic disease.
3. Complaints of cough with purulent sputum, increased body temperature to 39°C, pain in the left half of the chest. Has been ill for 2 months, the onset is caused by undercooling. The lag of the left half of the chest during breathing, the shortening of percussion sound over the lower lobe, by auscultation weakened breathing with amphoric sound. On X-ray of the chest the destruction cavity with the fibrous capsule in the projection of lower lobe of the left lung, infiltration of lung tissue is not determined. What is the primary diagnosis?
 - A. *Chronic lung abscess.
 - B. Pleural empyema.

- C. Acute lung abscess
 - D. Abscessing pneumonia.
 - E. Pyopneumothorax.
4. Complaints of cough with purulent sputum, increased body temperature to 39°C, pain in the left half of the chest. Has been ill for 2 weeks, the onset is caused by undercooling. The lag of the left half of the chest during breathing, the shortening of percussion sound over the lower lobe, by auscultation weakened breathing with amphoric sound. On the X-ray of chest the destruction cavity with the fluid level, with a clear thin-walled capsule in the projection of the lower lobe of the left lung. Infiltration of lung tissue is not determined. What is the primary diagnosis?
 - A. *Suppurative cyst of the lung.
 - B. Pleural empyema.
 - C. Acute lung abscess
 - D. Abscessing pneumonia.
 - E. Pyopneumothorax.
 5. Complaints of cough with purulent sputum, increased body temperature to 39°C, pain in the left half of the chest. Has been ill for 2 weeks, the onset is caused by undercooling. The lag of the left half of the chest during breathing, over the left lobe a dull percussion sound, by auscultation the breathing is absent. On X-ray of the chest the shadow in the basal parts of the left lung with an oblique upper level along Damuazo's line. What is the primary diagnosis?
 - A. *Pleural empyema.
 - B. Acute lung abscess
 - C. Chronic lung abscess.
 - D. Suppurative cyst of the lung.
 - E. Pyopneumothorax.
 6. Complaints of cough with purulent sputum, increased body temperature to 39°C, pain in the left half of the chest, dyspnea. Has been ill for 2 weeks, the onset is caused by undercooling. The lag of the left half of the chest during breathing, the shortening of percussion sound over the lower lobe, by auscultation the breathing is absent. On X-ray of the chest the shadow in the basal parts of the left lung with a horizontal fluid level and enlightenment over it. Is visible the edge of collapsed lung. What is the primary diagnosis?
 - A. *Limited pyopneumothorax.
 - B. Acute lung abscess
 - C. Chronic lung abscess.
 - D. Pleural empyema.
 - E. Total pyopneumothorax.
 7. Complaints of cough with foul-smelling purulent sputum with streaks of blood, increased body temperature to 40°C, pain in the left half of the chest, dyspnea at rest. Has been ill for 2 weeks, the onset is caused by undercooling. The lag of the left half of the chest during breathing, with a shortening of the pulmonary percussion sound, by auscultation moist rales over the left lung. On X-ray of the chest expressed infiltration of the left lung with multiple sites of destruction. What is the primary diagnosis?
 - A. *Gangrene of the lung.
 - B. Pleural empyema.
 - C. Acute lung abscess
 - D. Abscessing pneumonia.
 - E. Pyopneumothorax.
 8. Complaints of cough with foul-smelling purulent sputum with streaks of blood, increased body temperature to 40°C, pain in the left half of the chest, dyspnea at rest. Has been ill for 2 weeks, the onset is caused by undercooling. The lag of the left half of the chest during breathing, with a shortening of the pulmonary percussion sound, by auscultation moist rales over the lower lobe of the left lung. On X-ray of the chest expressed infiltration of left lung tissue with a giant cavity in the lower lobe with the level of the fluid. What is the primary diagnosis?
 - A. *Gangrenous abscess of lung.
 - B. Pleural empyema.

- C. Acute lung abscess
 - D. Abscessing pneumonia.
 - E. Gangrene of the lung.
9. Complaints of cough with purulent sputum, increased body temperature to 39°C, pain in the left half of the chest. Has been ill for 2 weeks, the onset is caused by undercooling. The lag of the left half of the chest during breathing, the shortening of percussion sound over the lower lobe, by auscultation weakened breathing. On X-ray of the chest paracostal fusiform shadow in the projection of the left lower lobe of the lung. What is the primary diagnosis?
- A. *Limited empyema.
 - B. Wide-spread pleural empyema.
 - C. Acute lung abscess
 - D. Chronic lung abscess.
 - E. Pyopneumothorax.
10. In the patient on the fourth day after the chest trauma on X-ray - heterogeneous shadow in the lower lobe. By puncture received a small amount of light yellow fluid with blood clots. What treatment are the best for the patient?
- A. *Drainage of the pleural cavity
 - B. Operational - lung decortication
 - C. Daily puncture
 - D. Resorbed therapy
 - E. Antibacterial therapy
11. In the patient, 48 years old, on the seventh day after the onset of a moderate pain in the chest, severe cough, fever to 39°C appeared the bad-smell sputum. The patient's condition remains grave, with expectoration more than 600 ml of gray-green sputum, and hectic fever. On X-ray – on the background of the heterogeneous shadow of the lower lobe of right lung revealed a cavity with a horizontal level of fluid. What is the primary diagnosis?
- A. *Abscess of the right lung
 - B. Gangrene of the right lung
 - C. Acute abscess of the right lung
 - D. Suppuration cyst of the right lung
 - E. Suppuration tuberculous cavern
12. In the patient, 35 years old, during the physical exertion appeared severe pain in the left half of the chest. Objectively: the patient is covered with cold sweat, dyspnea, pain during inspiration. By auscultation: vesicular breathing on the right side, on the left - is absent. Tachycardia, pulse 100 beats/min. What is the primary diagnosis?
- A. *Spontaneous pneumothorax
 - B. Angina pectoris
 - C. Acute myocardial infarction
 - D. Left-sided pleurisy
 - E. Pneumonia
13. The patient A., age 37, entered with complaints of cough with purulent sputum to 150 ml per day, pain in the right half of the chest, fever to 38°C. Has been ill for two weeks. The day before the entrance to the clinic during cough attack expectorated to 300 ml of purulent bad-smell sputum. On examination: a shortening of the pulmonary percussion sound under the right scapula, and the weakening of vesicular breathing. What is the primary diagnosis?
- A. *Acute lung abscess
 - B. Acute bronchitis
 - C. Exacerbation of chronic abscess
 - D. Exacerbation of bronchoectatic disease
 - E. Pleural empyema
14. Patient A., aged 42, had been treated for two months for an acute abscess of the upper lobe of right lung without improvement. The treatment: intramuscular injection of antibiotics, sulfanilamidns drugs. Remains the cough with purulent sputum to 80-100 ml per day, fever (37,6°C). What is the primary diagnosis?

- A. *Chronic lung abscess
 - B. Acute abscess of the right lung
 - C. Tuberculous cavern
 - D. Peripheral lung cancer
 - E. Suppurative cyst of lung
15. The patient, 78 years old, entered with complaints of pain in the left half of the chest, coughing, with daily 80 ml of mucopurulent sputum, fever to 37,2°C. The X-rays of the lower lobe of right lung revealed a cavity with irregular internal border and outside spicules with minor infiltration around. What is the primary diagnosis?
- A. *Hollow form of lung cancer
 - B. Chronic lung abscess
 - C. Suppuration cyst of lung
 - D. Fibro-cavernous tuberculosis
 - E. Limited empyema
16. The patient has a pyogenic lung abscess, which was complicated by repeated bleeding. The patient is undergoing the operative treatment. What antibiotics are the most suitable for preoperative prophylaxis?
- A. *Cephalosporins.
 - B. Penicillin.
 - C. Macrolides.
 - D. Aminoglycosides.
 - E. Fluorohinolones.
17. The patient with bilateral hydrothorax has undergone the repeat pleural puncture of both sides. After the last puncture felt the deterioration, fever, pain in the chest. Therapeutist on the next day during pleural puncture on the right obtained the pus. What is the mechanism of acute right-side empyema?
- A. *Contact-aspirating.
 - B. Lymphogenous.
 - C. Hematogenous.
 - D. Implantation.
 - E. Airborne.
18. The patient has the pyogenic lung abscess, which was complicated by bleeding. What medicines are the most suitable to stop the bleeding?
- A. *Vitamin K.
 - B. Anticoagulants.
 - C. Antibiotics.
 - D. Antiaggregants.
 - E. Prostaglandins.
19. The patient has the lung abscess, which was complicated by bleeding. What medicines are the most suitable to stop the bleeding?
- A. *Dicynon.
 - B. Heparin.
 - C. Penicillin.
 - D. Courantil.
 - E. Alprostan.
20. The patient has the lung abscess, which was complicated by bleeding to 200 ml. How this bleeding is classified?
- A. *I degree
 - B. 0 degree
 - C. II degree
 - D. III degree
 - E. IV degree
21. The patient received chest trauma 2 hours ago. Complains of the severe pain in the right half of the chest, dyspnea at rest. On examination: the lag of the right half of the chest during breathing,

- crepitation along the V-VI ribs on the right side, by percussion - tympanic sound, by auscultation - breathing is absent. What is the primary diagnosis?
- A. *Closed chest trauma. Fractures of V-VI ribs on the right side. Posttraumatic pneumothorax.
 - B. Closed chest trauma. Fractures of V-VI ribs on the right side.
 - C. Closed chest trauma. Fractures of V-VI ribs on the right side. Posttraumatic hemothorax.
 - D. Closed chest trauma. Fractures of V-VI ribs on the right side. Posttraumatic subcutaneous emphysema.
 - E. Closed chest trauma. Fractures of V-VI ribs on the right side. Posttraumatic complicated hemothorax.
22. The patient received chest trauma 2 hours ago. Complains of the severe pain in the right half of the chest, dyspnea at rest. On examination: the lag of the right half of the chest during breathing, crepitation along the V-VI ribs on the right side, by percussion - tympanic sound, by auscultation - breathing is absent. What additional examination is the most suitable?
- A. *Chest X-ray with contrast of the stomach
 - B. Plain X-ray of abdominal cavity
 - C. Esophagogastrosocopy
 - D. Computer tomography
 - E. Tomography of the chest
23. The patient received chest trauma 2 hours ago. Complains of the severe pain in the right half of the chest, dyspnea at rest. On examination: the lag of the right half of the chest during breathing, crepitation along the V-VI ribs on the right side, by percussion - tympanic sound, by auscultation - breathing is absent. The primary diagnosis: Closed chest trauma. Fractures of V-VI ribs on the right side. Posttraumatic pneumothorax. What is the typical treatment of rib fracture?
- A. *Novocaine block
 - B. External fixation of ribs
 - C. Intramedullary costal osteosynthesis;
 - D. Mechanical ventilation with positive end-expiratory pressure
 - E. Thoracotomy
24. The patient received chest trauma 2 hours ago. Complains of the severe pain in the right half of the chest, dyspnea at rest. On examination: the lag of the right half of the chest during breathing, crepitation along the V-VI ribs on the right side, by percussion - tympanic sound, by auscultation - breathing is absent. The primary diagnosis: Closed chest trauma. Fractures of V-VI ribs on the right side. Posttraumatic pneumothorax. What is the treatment of pneumothorax?
- A. *Pleural drainage
 - B. Pleural puncture
 - C. Thoracotomy
 - D. Pneumonectomy, bilobectomy, lobectomy
 - E. Conservative treatment
25. The patient received chest trauma 2 hours ago. Complains of the severe pain in the right half of the chest, dyspnea at rest. On examination: the lag of the right half of the chest during breathing, crepitation along the V-VI ribs on the right side, by percussion - tympanic sound, by auscultation - breathing is absent. The primary diagnosis: Closed chest trauma. Fractures of V-VI ribs on the right side. Posttraumatic pneumothorax. Where the drainage of pleural space in pneumothorax is performed?
- A. *II intercostal space, midclavicular line
 - B. II intercostal space, scapular line
 - C. IV intercostal space, anterior axillary line
 - D. VII intercostal space, midclavicular line
 - E. VII intercostal space, scapular line
26. The patient received chest trauma 14 days ago. Complains of a moderate pain in the right half of the chest, dyspnea, fever up to 38,5°C. Lag of the right half of the chest during breathing,

narrowing of the intercostal spaces. By percussion - a shortening of the percussion sound over the right lung, by auscultation - weakening of breathing. What is the primary diagnosis?

- A. *Right-side suppurative hemothorax.
 - B. Right-side posttraumatic pneumonia.
 - C. Right-side hemothorax.
 - D. Right-side pyopneumothorax.
 - E. Consolidated rib fractures.
27. Was pressed by the truck to the wall. Complains of the expressed dyspnea, difficult breathing, chest pain. On examination the expressed cyanosis. The frequency of respiratory movements - 26-28 per 1 min. Unstable hemodynamics. The chest is deformed, abnormal mobility of the front wall. The swelling of soft tissues of the neck with crepitation. What is the primary diagnosis?
- A. *Mediastinal emphysema.
 - B. Posttraumatic pneumothorax.
 - C. Posttraumatic hemothorax.
 - D. Posttraumatic pneumonia
 - E. Subcutaneous emphysema.
28. Was pressed by the truck to the wall. Complains of the expressed dyspnea, difficult breathing, chest pain. On examination the expressed cyanosis. The frequency of respiratory movements - 26-28 per 1 min. Unstable hemodynamics. The chest is deformed, abnormal mobility of the front wall. The swelling of soft tissues of the neck with crepitation. The primary diagnosis: Mediastinal emphysema. What is the treatment of mediastinal emphysema?
- A. *Drainage of anterior mediastinum
 - B. Conservative treatment
 - C. Drainage of pleural cavity
 - D. Novocaine block
 - E. Pericardial puncture
29. Was pressed by the truck to the wall. Complains of the expressed dyspnea, difficult breathing, chest pain. On examination the expressed cyanosis. The frequency of respiratory movements - 26-28 per 1 min. Unstable hemodynamics. The chest is deformed, abnormal mobility of the front wall. The swelling of soft tissues of the neck with crepitation. The primary diagnosis: Mediastinal emphysema. What is the main cause of mediastinal emphysema?
- A. *Disruptions of trachea, bronchi
 - B. Rib fracture
 - C. Pneumothorax
 - D. Hemothorax
 - E. Mediastinal tumours
30. Was pressed by the truck to the wall. Complains of the expressed dyspnea, difficult breathing, chest pain. On examination the expressed cyanosis. The frequency of respiratory movements - 26-28 per 1 min. Unstable hemodynamics. The chest is deformed, abnormal mobility of the front wall. The swelling of soft tissues of the neck with crepitation. The primary diagnosis: Mediastinal emphysema. What does the mediastinal emphysema result in?
- A. *Cardiac tamponade
 - B. Hemoptysis
 - C. Pleural empyema
 - D. Pneumothorax
 - E. Lung atelectasis
31. Female patient, 62 years old, was got in accident. On examination was detected the region of the right half of the chest, which disengages during inspiration. What are the most appropriate therapeutic measures?
- A. *External fixation of a floating area
 - B. Introduction of narcotic analgetics
 - C. Vagosympathetic block by Vishnevsky
 - D. Tight chest bandage

- E. Paravertebral blockade
32. In the patient after the accident with multiple rib fracture during the puncture of pleural cavity received the gastric content. What additional examination is the most suitable?
- A. *Chest X-ray with contrast of the stomach
 - B. Plain X-ray of abdominal cavity
 - C. Esophagogastroscope
 - D. Computer tomography
 - E. Tomography of the chest
33. In the patient on the fourth day after the chest trauma on X-ray - heterogeneous shadow in the lower lobe. By puncture received a small amount of light yellow fluid with blood clots. What treatment are the best for the patient?
- A. *Drainage of the pleural cavity
 - B. Operational - lung decortication
 - C. Daily puncture
 - D. Resorbed therapy
 - E. Antibacterial therapy
34. In the patient after blunt chest trauma with a sternum fracture appeared the weakness, hypotension, cyanosis of the upper half of the body, distension of the neck veins. By pleural puncture the content is absent. Pulse 120 beats per min, rhythmic, weakened. What is the primary diagnosis?
- A. *Cardiac tamponade
 - B. Pulmonary embolism
 - C. Contusion of the heart
 - D. Acute myocardial infarction
 - E. Coagulated hemopericardium
35. The patient entered in 3 hours after the injury with expressed subcutaneous emphysema of the upper half of the body, dyspnea, tachycardia, pulse - 120 beats/min. On X-ray the pneumothorax was found out with significantly enlargement of the mediastinum in both sides. What is the first aid?
- A. *Drainage of the anterior mediastinum
 - B. Puncture of the pleural cavity
 - C. Drainage of the pleural cavity
 - D. Thoracoscopy
 - E. Thoracotomy
36. The patient entered in 3 hours after the injury with expressed subcutaneous emphysema of the upper half of the body, dyspnea, tachycardia, pulse - 120 beats/min. On X-ray the pneumothorax was found out with significantly enlargement of the mediastinum in both sides. What is the primary diagnosis?
- A. *Mediastinal emphysema.
 - B. Posttraumatic pneumothorax.
 - C. Posttraumatic hemothorax.
 - D. Posttraumatic pneumonia
 - E. Subcutaneous emphysema.
37. Patient S., 25 years old, entered the hospital after the chest trauma. During clinical and X-ray examination was diagnosed the left-side tension pneumothorax. What is the first aid?
- A. *Drainage of the pleural cavity
 - B. Intravenous infusion
 - C. Oxygenotherapy
 - D. Intubation
 - E. Analgesics
38. Patient S., 25 years old, entered the hospital after the chest trauma. During clinical and X-ray examination was diagnosed the left-side tension pneumothorax. Where the drainage of pleural space in pneumothorax is performed?
- A. *II intercostal space, midclavicular line

- B. II intercostal space, scapular line
 - C. IV intercostal space, anterior axillary line
 - D. VII intercostal space, midclavicular line
 - E. VII intercostal space, scapular line
39. Patient S., 35 years old, entered the hospital after the chest trauma. During clinical and X-ray examination was diagnosed the left-side hemothorax. Where the drainage of pleural space in hemothorax is performed?
- A. *VII intercostal space, scapular line
 - B. II intercostal space, midclavicular line
 - C. II intercostal space, scapular line
 - D. IV intercostal space, anterior axillary line
 - E. VII intercostal space, midclavicular line
40. Patient S., 35 years old, entered the hospital after the chest trauma. During clinical and X-ray examination was diagnosed the left-side hemothorax. What method is the most informative in the diagnostic of hemothorax?
- A. *Pleural puncture
 - B. General blood analysis
 - C. Sputum analysis
 - D. Auscultation
 - E. X-ray examination
41. Patient S., 35 years old, entered the hospital after the chest trauma. During clinical and X-ray examination was diagnosed the left-side hemothorax. What test is used to determine the continuity of pleural bleeding?
- A. *Revilour-Greguar's test
 - B. Troyanov-Trendelenburg's test
 - C. Talman's test
 - D. Mayo-Pratt's test
 - E. Delbe-Pertess test (marching test)
42. In the patient, 35 years old, during the physical exertion appeared severe pain in the left half of the chest. Objectively: the patient is covered with cold sweat, dyspnea, pain during inspiration. By auscultation: vesicular breathing on the right side, on the left - is absent. Tachycardia, pulse 100 beats/min. What is the primary diagnosis?
- A. *Spontaneous pneumothorax
 - B. Angina pectoris
 - C. Acute myocardial infarction
 - D. Left-sided pleurisy
 - E. Pneumonia
43. 54 years old patient complains of dysphagia. Two years ago noticed on the left side of neck the appearance of protrusion after eating, vomiting by food, night cough. Began to lose his weight. On X-ray of esophagus with barium at the level of the clavicle was revealed the depot of barium like chicken egg by the size and shape. What is the most probable diagnosis?
- A. *Diverticulum of the esophagus
 - B. Esophagotraheal fistula
 - C. Esophageal cancer
 - D. Stenosis of the esophagus
 - E. Esophageal achalasia
44. 54 years old patient complains of dysphagia. Two years ago noticed on the left side of neck the appearance of protrusion after eating, vomiting by food, night cough. Began to lose his weight. On X-ray of esophagus with barium at the level of the clavicle was revealed the depot of barium like chicken egg by the size and shape. What complication is probable for this disease?
- A. *Diverticulitis
 - B. Obstructive jaundice
 - C. Intestinal obstruction
 - D. Myocardial infarction

- E. Lung atelectasis
45. 54 years old patient complains of dysphagia. Two years ago noticed on the left side of neck the appearance of protrusion after eating, vomiting by food, night cough. Began to lose his weight. On X-ray of esophagus with barium at the level of the clavicle was revealed the depot of barium like chicken egg by the size and shape. What is the typical treatment of this disease?
- A. *Surgical treatment
 - B. Spasmolytics
 - C. Analgetics
 - D. Nonsteroid antiinflammatory drugs
 - E. Antibiotics
46. 54 years old patient complains of dysphagia. Two years ago noticed on the left side of neck the appearance of protrusion after eating, vomiting by food, night cough. Began to lose his weight. On X-ray of esophagus with barium at the level of the clavicle was revealed the depot of barium like chicken egg by the size and shape. What operation is performed in this disease?
- A. *Resection of diverticulum
 - B. Esophagomyotomy
 - C. Esophagogastric anastomosis
 - D. Extirpation of esophagus
 - E. Esophageal plastics by intestine
47. To the hospital entered a man in the critical condition: acrocyanosis, dyspnea, subcutaneous emphysema on the neck and upper part of body. Complains of severe pain behind the breastbone and epigastrium. The body temperature of 38,9°C, pulse 130 beats/min, blood pressure 80/50 mm Hg. From anamnesis 6 years ago after drinking appeared the vomit, which resulted in the signatic. What is the primary diagnosis?
- A. *Spontaneous rupture of esophagus
 - B. Incarceration of paraesophageal hernia
 - C. Spontaneous pneumothorax
 - D. Pulmonary embolism
 - E. Perforated ulcer
48. 38-year-old woman complains of difficulty passing of food through esophagus, periodic vomiting. Has been ill for 1,5 years. Last 6 months notes appearance of food on the pillow during sleep. Lost 15 kg of body weight. There were constipations, stool once in 3-4 days. On plain X-ray film the absence of the gas bubble of the stomach. What is the most probable diagnosis?
- A. *Achalasia of esophagus
 - B. Peptic stenosis of the esophagus
 - C. Esophageal cancer
 - D. Diverticulum of the esophagus
 - E. Sliding esophageal hernia
49. 38-year-old woman complains of difficulty passing of food through esophagus, periodic vomiting. Has been ill for 1,5 years. Last 6 months notes appearance of food on the pillow during sleep. Lost 15 kg of body weight. There were constipations, stool once in 3-4 days. On plain X-ray film the absence of the gas bubble of the stomach. What stage of dysphagia relates to such manifestations?
- A. *II
 - B. I
 - C. III
 - D. IV
 - E. V
50. 38-year-old woman complains of difficulty passing of food through esophagus, periodic vomiting. Has been ill for 1,5 years. Last 6 months notes appearance of food on the pillow during sleep. Lost 15 kg of body weight. There were constipations, stool once in 3-4 days. On plain X-ray film the absence of the gas bubble of the stomach. What is the roentgenological sign of this disease in contrast X-ray with barium?

- A. *"Rat tail" sign
 - B. Filling defects
 - C. "Niche" sign
 - D. "Bell" sign
 - E. Blunt His angle
51. 38-year-old woman complains of difficulty passing of food through esophagus, periodic vomiting. Has been ill for 1,5 years. Last 6 months notes appearance of food on the pillow during sleep. Lost 15 kg of body weight. There were constipations, stool once in 3-4 days. On plain X-ray film the absence of the gas bubble of the stomach. What is the main method of diagnostic of this disease?
- A. *X-ray examination with barium swallow
 - B. Pleural punctere
 - C. Ultrasound examination
 - D. Plain X-ray examination of the chest
 - E. Irrigoscopy
52. On X-ray of the esophagus in the right lateral projection in the middle third on the front wall was found out the additional shadow, of round shape with smooth contours to 2 cm in diameter. What is the most probable diagnosis?
- A. *Diverticulum of the esophagus
 - B. Achalasia of the esophagus
 - C. Esophageal cancer
 - D. Chemical burn of the esophagus
 - E. Diaphragmatic hernia
53. The tool dilation of burn and peptic stricture of the esophagus has a risk of perforation with the development of purulent mediastinitis and pleural empyema. What is the least dangerous method for perforation should be applied in the first attempt of dilation of the stricture?
- A. *Dilatation of the stricture by balloon dilatator with a stable diameter of the cylinder.
 - B. Bouginage under the control of esophagoscope.
 - C. Bouginage along the metal conductor.
 - D. The blind bouginage under local anesthesia.
 - E. Bouginage under the control of X-ray
54. Female complains of difficult passing of food through esophagus, vomiting by unchanged food, regurgitation in night and weight loss. Anamnesis about 10 years. On X-ray study revealed achalasia of esophagus of the IV stage with S-shaped deformation. What is the optimal treatment?
- A. *Operation esophagocardiomyotomy with plastic by the stomach fundus.
 - B. Cardiodilatation by hard probe.
 - C. Cardiodilatation balloon probe.
 - D. Operation esophago-fundoanastomosis by Heyrovsky.
 - E. Resection of the cardia with esophageal anastomosis.
55. Female complains of difficult passing of food through esophagus, vomiting by unchanged food, regurgitation in night and weight loss. Anamnesis about 10 years. On X-ray study revealed achalasia of esophagus of the IV stage. What is the characteristic feature of the IV stage of this disease?
- A. *Considerable esophageal dilation with S-shaped elongation.
 - B. Cicatrical changes with expressed esophageal dilation, the peristalsis is absent
 - C. Asymptomatic
 - D. Functional spasm without esophageal dilation
 - E. Constant spasm with a moderate esophageal dilation and maintained peristalsis
56. Patient 52 entered the clinic with complaints of complete obstruction of the esophagus, salivation, weakness, t-38,7°C. Dysphagia has been for 8 days, after the swallowing of piece of the meat with bone. On X-ray the barium delays at the middle third of the esophagus. On fibroesophagoscopy was found a wedged bone with hyperemia and edema of the mucous membrane, covered by fibrin. What is the optimal treatment strategy in this case?

- A. *Surgical treatment: thoracotomy, esophagotomy, removal of foreign body (bone), suturing of the esophagus + gastrostomy.
 - B. Endoscopic removal of foreign body by rigid esophagoscope
 - C. Pushing of foreign body in the stomach by bougie.
 - D. Removal of foreign body by the Fogarty's probe
 - E. Removal of foreign body by fiberoptic endoscope.
57. Among the methods of esophageal plastic the most physiologic and safe modern method is:
- A. *Isoperistaltic plastic by tube of the greater curvature of the stomach after the extirpation of the esophagus through a cervical-laparotomy access.
 - B. Large intestine plastic in antiperistaltic position of the transplant.
 - C. Large intestine plastic in isoperistaltic position of the transplant.
 - D. Large intestine plastic with a skin flap.
 - E. Large intestine plastic by ileocecal segment.
58. The patient has the postburn stenosis of the esophagus. After the next bouginage felt the fever, tachycardia, pain behind the breastbone. On X-ray: the horizontal level of fluid in the posterior mediastinum. What is the most probable diagnosis?
- A. *Acute posterior mediastinitis.
 - B. Acute anterior mediastinitis.
 - C. Diverticulum of the esophagus.
 - D. Acute pleural empyema.
 - E. Paraesophageal hernia.
59. Complaints of burning, pain behind the breastbone, loss of weight. Has been ill for 7 months. Last 2 weeks noticed difficult passing of solid food. On contrasting X-ray was diagnosed: filling defect of lower thoracic part of the esophagus, a "niche" sign of the lesser curvature of stomach. What is the most probable diagnosis?
- A. *Gastric ulcer
 - B. Paraesophageal hernia
 - C. Decompensated pyloric stenosis
 - D. Sliding esophageal hernia
 - E. Peptic duodenal ulcer
60. Complaints of the pain behind the breastbone, difficult passage of solid food, weight loss, dizziness. Has been ill for 3 months. Last 2 days disturbs the vomiting after fluid food, the stagnation of fluid food. On EGDS severe narrowing of the esophagus, rigidity of the walls, hyperemic mucosa without folds. What is the most probable diagnosis?
- A. *Esophageal cancer
 - B. Sliding esophageal hernia
 - C. Paraesophageal hernia
 - D. Reflux esophagitis
 - E. Varicose veins of the esophagus
61. In the patient six months ago appeared the complaints of pain behind the sternum and a strong burning sensation in the esophagus. Sometimes observed dysphagia. On X-ray examination found the presence of diverticulum of the left wall of esophagus at the level of tracheal bifurcation 3?4 cm, just below the aortic arch. The patient was not treated. What tactics of treatment should be choused?
- A. *Right-side thoracotomy, diverticulectomy.
 - B. Left-side thoracotomy, diverticulectomy.
 - C. Right-side thoracotomy, resection of the esophagus.
 - D. Large intestine plastic of esophagus
 - E. Large intestine plastic of esophagus
62. The woman aged 52 complains of pain behind the breastbone, difficult passing of solid food through esophagus, increased salivation. The doctor advised 0,1 % solution of atropine before eating. After 3 days on X-rays no pathology was revealed. The doctor should do for this patient:
- A. *Send to fibroesophagoscopy
 - B. Allow the job

- C. Control visit after 2 months
 - D. Treatment by spasmolytics
 - E. Send to ECG
63. The woman, 38 years old, complains of difficulty passage of solid meal on esophagus, vomiting by undigested food, night regurgitation (sign of „wet pillow“), loss of weight. Has been ill for 10 years. On X-ray examination with barium the sign of "rat tail", dilation of the esophagus to 6 cm with maintained peristalsis. What stage of achalasia is there in this patient?
- A. *II
 - B. I
 - C. 0
 - D. III
 - E. IV
64. 53 year old man complains of recurrent pain behind the breastbone, heartburn, especially in the horizontal position. Sometimes the burning pain behind the sternum occurs after hot or spicy food. Two weeks ago was vomiting by blood and lost of consciousness. Has entered the hospital after repeated gastric bleeding. What is the most probable diagnosis?
- A. *Sliding esophageal hernia, reflux esophagitis
 - B. Diverticulum of the esophagus
 - C. Varicose veins of the esophagus
 - D. Mallory-Weiss syndrome
 - E. Crohn's disease.
65. 53 year old man complains of recurrent pain behind the breastbone, heartburn, especially in the horizontal position. Sometimes the burning pain behind the sternum occurs after hot or spicy food. Two weeks ago was vomiting by blood and lost of consciousness. Has entered the hospital after repeated gastric bleeding. What roentgenological sign confirms the pathology?
- A. *"Bell" sign
 - B. "Rat tail" sign
 - C. Filling defects
 - D. "Bird-beak" sign
 - E. Esophageal dilatation
66. 53 year old man complains of recurrent pain behind the breastbone, heartburn, especially in the horizontal position. Sometimes the burning pain behind the sternum occurs after hot or spicy food. Two weeks ago was vomiting by blood and lost of consciousness. Has entered the hospital after repeated gastric bleeding. What drugs are used for the treatment of this pathology?
- A. *Blockers of proton pump
 - B. Spasmolytics
 - C. Adrenoblockers
 - D. Blockers of calcium channel
 - E. Anticoagulants
67. 53 year old man complains of recurrent pain behind the breastbone, heartburn, especially in the horizontal position. Sometimes the burning pain behind the sternum occurs after hot or spicy food. Two weeks ago was vomiting by blood and lost of consciousness. Has entered the hospital after repeated gastric bleeding. What disease should be this pathology differentiated from?
- A. *Peptic ulcer
 - B. Pancreatitis
 - C. Intestinal obstruction
 - D. Cholecystitis
 - E. Bronchial asthma
68. 53 year old man complains of recurrent pain behind the breastbone, heartburn, especially in the horizontal position. Sometimes the burning pain behind the sternum occurs after hot or spicy food. Two weeks ago was vomiting by blood and lost of consciousness. Has entered the hospital after repeated gastric bleeding. What is the main treatment of this pathology?
- A. *Conservative treatment
 - B. Esophagostomy

- C. Esophageal plastic
 - D. Resection of the esophagus
 - E. Resection of the stomach
69. 53 year old man complains of recurrent pain behind the breastbone, heartburn, especially in the horizontal position. Sometimes the burning pain behind the sternum occurs after hot or spicy food. Two weeks ago was vomiting by blood and lost of consciousness. Has entered the hospital after repeated gastric bleeding. What type of operation is used for treatment of this pathology?
- A. *Cruroplasty with Nissen's fundoplication
 - B. Esophagostomy
 - C. Cruroplasty
 - D. Resection of the esophagus
 - E. Resection of the stomach
70. After the birth of the child appeared the signs of respiratory failure. By auscultation on the left side the breathing is absent. On X-ray expressed mediastinal shift to the right, the presence of protrusion on the left side. What is the most probable diagnosis?
- A. *Left-sided diaphragmatic hernia
 - B. Hypoplasia of right lung
 - C. Polycystosis of the left lung
 - D. Relaxation of the diaphragm
 - E. Esophageal stricture
71. The patient, 45 years old, complains of retrosternal pain, which increase at night, heartburn, belching. Has been ill for 4 months. What research is the most appropriate?
- A. *X-ray contrast study in Trendelenburg's position.
 - B. Plain chest X-ray
 - C. Fibroesophagogastroduodenoscopy
 - D. Plain X-ray of the abdominal cavity.
 - E. Computer tomography
72. The patient, 45 years old, complains of retrosternal pain, which increase at night, heartburn, belching. Has been ill for 4 months. What is the most probable diagnosis?
- A. *Sliding esophageal hernia, reflux esophagitis
 - B. Diverticulum of the esophagus
 - C. Varicose veins of the esophagus
 - D. Mallory-Weiss syndrome
 - E. Crohn's disease.
73. What is the most wide-spread cause of the peptic stricture of esophagus associated with reflux-esophagitis?
- A. *Sliding esophageal hernia.
 - B. Prolonged nasogastric intubation in the esophagus.
 - C. Short stay nasogastric intubation.
 - D. Frequent vomiting of pregnancy.
 - E. Achalasia of the esophagus
74. X-ray signs: the "bell" sign, blunt Hiss angle, absence of gas bubble of the stomach are characteristic for:
- A. *Sliding esophageal hernia.
 - B. Paraesophageal hernia.
 - C. Relaxation of the diaphragm.
 - D. Malignant tumor of the esophagus.
 - E. Achalasia of the esophagus
75. The patient has the pain behind the breastbone, heartburn, which increases after the meal. Has been ill for 6 months. For 5 days has a black chair. On X-ray examination revealed the "bell" sign, blunt Hiss angle, absence of gas bubble of the stomach. What is the most probable diagnosis?
- A. *Sliding esophageal hernia.
 - B. Paraesophageal hernia.

- C. Relaxation of the diaphragm.
 - D. Malignant tumor of the esophagus.
 - E. Achalasia of the esophagus
76. Complaints of heaviness in the epigastric region, nagging pain after eating. When EGDS pathology identified. On X-ray examination pronounced gas bubble of the stomach is visible to the level III intercostal space on the left. What is the most probable diagnosis?
- A. *Relaxation of the diaphragm.
 - B. Paraesophageal hernia.
 - C. Sliding esophageal hernia.
 - D. Malignant tumor of the esophagus.
 - E. Achalasia of the esophagus.
77. The patients with sliding esophageal hernia mostly complain of:
- A. *Heartburn, pain behind the breastbone.
 - B. Difficult passage of food, loss of weight.
 - C. The pain behind the breastbone, difficulty in food passage.
 - D. Pain in the epigastric region with irradiation into the right hypochondrium.
 - E. Pain in the epigastric region with irradiation into the back.
78. Complications paraesophageal hernias of esophagus:
- A. *Incarceration
 - B. Malignancy.
 - C. Esophageal stricture.
 - D. Dysphagia.
 - E. Reflux esophagitis.
79. In the patient at night appeared a severe pain in the epigastric region, nausea, vomiting. 6 months ago was diagnosed paraesophageal hernia. What complication arose?
- A. *Incarceration
 - B. Malignancy.
 - C. Esophageal stricture.
 - D. Dysphagia.
 - E. Reflex esophagitis.
80. In the patient at night appeared a severe pain in the epigastric region, nausea, vomiting. 6 months ago was diagnosed paraesophageal hernia. What type of operation is indicated for this patient?
- A. *Cruroplasty
 - B. Esophagostomy
 - C. Resection of the esophagus
 - D. Resection of the stomach
 - E. Cruroplasty with Nissen's fundoplication
81. Complaints of heartburn, pain behind the breastbone, regurgitation of food. Has been ill for 2 months. On X-ray examination revealed the "bell" sign, blunt Hiss angle, absence of gas bubble of the stomach. Your tactics?
- A. *Conservative therapy.
 - B. Bougienage of esophagus.
 - C. Surgical intervention.
 - D. Large-intestinal plastic of esophageal cardia.
 - E. Small-intestinal plastic of esophageal cardia.
82. The patient has the postburn stenosis of the esophagus. After the next bougienage felt the fever, tachycardia, pain behind the breastbone. On X-ray: the horizontal level of fluid in the posterior mediastinum. What is the most probable diagnosis?
- A. *Acute posterior mediastinitis.
 - B. Acute anterior mediastinitis.
 - C. Diverticulum of the esophagus.
 - D. Acute pleural empyema.
 - E. Paraesophageal hernia.

83. Complaints of burning, pain behind the breastbone. Has been ill for 4 months. On contrasting X-ray was diagnosed: the "bell" sign, the absence of gas bubble of the stomach, blunt Hiss angle. What is the most probable diagnosis?
- *Sliding esophageal hernia
 - Paraesophageal hernia
 - Gastric ulcer
 - Peptic duodenal ulcer
 - Decompensated pyloric stenosis
84. 5 hours ago, after the bouginage of esophageal cicatrice stricture appeared the pain behind the breastbone, a feeling of compression, subcutaneous crepitation on the neck, fever to 38,5°C. On examination the weakening of the heart tones by auscultation. On plain X-ray of chest – mediastinal emphysema, mediastinal extension of the shadows. What is the most probable diagnosis?
- *Acute mediastinitis
 - Reflux esophagitis
 - Sliding esophageal hernia
 - Paraesophageal hernia
 - Achalasia of the esophagus
85. A 34-year-old female with hypertension is considering to become a pregnant. Which of the following medications would be absolutely contraindicated to control her BP during pregnancy?
- Methyldopa
 - Metoprolol
 - Labetalol
 - *Captopril
 - Nifedipine
86. A 34-year-old male with isolated essential hypertension came to clinic and it was found high BP of 180/100 mm Hg after failure of behavioral modifications. What is the most appropriate next step?
- Start hydrochlorothiazide
 - *Start hydrochlorothiazide and lisinopril
 - Repeat BP in 4 weeks
 - Start amlodipine
 - Start doxazosin
87. A 34-year-old male with isolated essential hypertension came to clinic and it was found high BP of 180/100 mm Hg item after failure of behavioral modifications. What is the most appropriate next step?
- Start hydrochlorothiazide
 - *Start hydrochlorothiazide and lisinopril
 - Repeat BP in 4 weeks
 - Start amlodipine
 - Start doxazosin
88. A 40-year-old diabetic patient with a blood pressure (BP) of 145/90 mm Hg item and proteinuria. Which BP profile represents the best therapeutic goal for this patient?
- 160/90
 - 140/90
 - 130/85
 - *125/75
 - 140/85
89. A 40-year-old diabetic patient presents with a blood pressure (BP) of 145/90 mm Hg item and proteinuria. What is the best medication for the initial management of this patient's hypertension?
- Calcium channel blockers
 - Beta blockers
 - *ACE-inhibitors / angiotensin receptor blockers

- D. Alpha blockers
 - E. Diuretics
90. A 42-year-old female with chronic obstructive pulmonary disease is found on multiple office visits to have elevated BP measurements. Which of the following medications is contraindicated?
- A. Hydrochlorothiazide
 - B. Metoprolol
 - C. Lisinopril
 - D. *None of above
 - E. All of the above
91. A 42-year-old male comes in for a routine physical examination. He is noted to have impaired glucose methabolism, and a BP of 135/85 mmHg. What is the best treatment plan for this individual?
- A. *Aggressive lifestyle modification
 - B. Institute thiazide diuretic regimen
 - C. No treatment at this time
 - D. Initiate an ACE-inhibitor
 - E. Initiate a beta-blocker
92. A 45-year-old male comes in for a routine physical examination. He is noted to have impaired glucose methabolism, and a BP of 140/85 mmHg. What is the best treatment plan for this individual?
- A. *Aggressive lifestyle modification
 - B. Institute thiazide diuretic regimen
 - C. No treatment at this time
 - D. Initiate an ACE-inhibitor
 - E. Initiate a beta-blocker
93. A 48-year-old male with diabetes mellitus, hypertension, and hyperlipidemia has a hypertensive emergency. His arterial pressure is 150/100 mmHg item. Which medications would be most appropriate therapy for this patient?
- A. *Nitroprusside
 - B. Enteral metoprolol
 - C. Fenoldopam
 - D. Intravenous nitroglycerine
 - E. Any of the above
94. ?A 48-year-old obese male with hypertension, dyslipidemia, and diabetes mellitus presents to the outpatient clinic for his yearly physical. He has refused medications in the past, but now is willing to consider treatment. His BP is 145/95 mmHg with a HR of 80 bpm. His laboratory data are significant for the presence of microalbuminuria. Which of the following medications would be the most appropriate?
- A. Carvedilol
 - B. Methyldopa
 - C. *Lisinopril
 - D. Chlorthalidone
 - E. Terazosin
95. A 48-year-old obese male with hypertension, dyslipidemia, and diabetes mellitus presents to the outpatient clinic for his yearly physical. He has refused medications in the past, but now is willing to consider treatment. His BP is 145/95 mmHg with a HR of 80 bpm. His laboratory data are significant for the presence of microalbuminuria. Which of the following medications would be the most appropriate?
- A. Carvedilol
 - B. Methyldopa
 - C. *Lisinopril
 - D. Chlorthalidone
 - E. Terazosin

96. A 56-year-old male on hydralazine, hydrochlorothiazide, lisinopril, and metoprolol begins to develop a malar rash and arthralgias. Which of the above antihypertensive agents is known to cause drug-induced lupus?
- Hydrochlorothiazide
 - Lisinopril
 - *Hydralazine
 - Metoprolol
 - None of the above
97. A 53-year-old male on hydralazine, hydrochlorothiazide, lisinopril, and metoprolol begins to develop a malar rash and arthralgias. Which of the above antihypertensive agents is known to cause drug-induced lupus?
- Hydrochlorothiazide
 - Lisinopril
 - *Hydralazine
 - Metoprolol
 - None of the above
98. A 60-year old white man consults you with a headache. Examination data are unremarkable, except that the blood pressure is raised and subsequent measurements confirm readings of 170/106 mmHg. He is obese, smokes 15 cigarettes per day and drinks 2 pints of beer per day. His investigations reveal a cholesterol of 6 mmol/l with a normal blood sugar and electrolyte profile and normal renal function. There is no evidence of target organ damage.
- This man needs immediate treatment with antihypertensive drugs, aspirin and a statin
 - *Initiate antihypertensive therapy with two-drug combination
 - At this age it is far more important to control the hyperlipidaemia than the BP
 - This man's blood pressure could be wholly ascribed to his alcohol intake
 - This patient can be observed and counseled on maintaining a reasonable BMI
99. A 62-year-old man with isolated essential hypertension, currently taking hydrochlorothiazide 25 mg PO daily, comes to you for his first clinic visit. He notes that his BP at home is always less than 140/80 mmHg, but in clinic it is always at least 155/95 mmHg. What is the next step?
- Increase dose of thiazide
 - Addition of second antihypertensive medication
 - *Do nothing as he has white coat hypertension
 - Evaluate for secondary causes of hypertension
 - Start metoprolol
100. A 62-year-old man with isolated essential hypertension, currently taking hydrochlorothiazide 25 mg PO daily, comes to you for his first clinic visit. He notes that his BP at home is always less than 140/80 mmHg item, but in clinic it is always at least 155/95 mmHg. What is the next step?
- Increase dose of thiazide
 - Addition of second antihypertensive medication
 - *Do nothing as he has white coat hypertension
 - Evaluate for secondary causes of hypertension
 - Start metoprolol
101. At a routine examination, an asymptomatic 46-year-old man is found to have a BP of 150/110 mmHg item, but no other abnormalities are present. What do you do next?
- Reassure the patient and repeat the physical examination in 12 months
 - Initiate antihypertensive therapy
 - *Obtain repeated BP recordings in your office and/or the patient's home or work site
 - Hospitalize patient for renal arteriography
 - Order a 24-h ambulatory BP monitoring
102. For the case below, select the most significant adverse effect of the antihypertensive and/or cardiac agent in question: a 45-year old female has been on diuretic, but BP remains elevated at 145/95, leading to the proposed addition of lisinopril. Which key potential adverse effect should be discussed?

- A. Increased triglyceride levels
 - B. Peripheral edema
 - C. Lupus-like syndrome
 - D. *Cough
 - E. Gynecomastia
103. For the case below, select the most significant adverse effect of the antihypertensive and/or cardiac agent in question: a 58-year old male truck driver has significant hypertension, still not controlled on a diuretic plus calcium channel blocker. Clonidine is being considered as the next medication, but in this patients is concerned by sedation, sexual dysfunction.
- A. Increased triglyceride levels
 - B. Cough
 - C. Gynecomastia
 - D. *Rebound hypertension
 - E. Urinary retention
104. For the case below, select the most significant adverse effect of the antihypertensive and/or cardiac agent in question: a 68-year old male with advanced chronic heart failure and BP 145/90 will have spironolactone therapy, but should be informed about possible side effect.
- A. Increased triglyceride levels
 - B. Peripheral edema
 - C. Lupus-like syndrome
 - D. Cough
 - E. *Gynecomastia
105. In patients with a history of stroke or TIA the preferred drug combination is:
- A. *ACE-inhibitor and diuretic
 - B. Calcium-channel blocker and beta-blocker
 - C. Beta-blocker and diuretic
 - D. Angiotensin receptor blocker and beta blocker
 - E. Beta- and alpha blocker
106. The initial antihypertensive medication recommended for patients who have no compelling indications or contraindications is
- A. ACE-inhibitor
 - B. Calcium-channel blocker
 - C. Diuretics
 - D. Beta blocker
 - E. *Any of the above
107. To reduce the patient's cardiovascular morbidity and mortality, which therapy would you prescribe?
- A. Hydralazine
 - B. Atenolol
 - C. *Losartan
 - D. Doxazosin
 - E. Clonidine
108. What is the appropriate course of action regarding the patient's antihypertensive therapy?
- A. Advise a low-sodium diet
 - B. *Finish doxazosin therapy and consider an alternative agent
 - C. Advise high dietary intake of calcium and potassium
 - D. Increase the doxazosin to 4 mg a day
 - E. Advise magnesium supplements
109. You see a diabetic patient presents with BP readings that are 155/95 or higher. All of the following statements about the treatment of this patient's hypertension are correct EXCEPT:
- A. Pharmacologic blockade of the renin-angiotensin system reduces the risk of both microvascular and macrovascular events
 - B. Aggressive BP control reduces cardiovascular events more in diabetics than in nondiabetics

- C. *Calcium channel blockers show no benefit in reducing cardiovascular events
 - D. The goal BP for this patient is <130/80 mmHg
 - E. All the above statements are correct
110. During the operation concerning strangular impassability of bowels, which conducted under general anaesthesia of i/v with ALV, at a patient the stop of cardiac diyal-nosti happened 50 years in the moment of mesenretium streching by the surgeon. What would prevent the stop of heart in this case?
- A. *i/v injection atropin
 - B. i/v injection of cardiac glycozidis
 - C. Deepening of general anaesthesi
 - D. Additional injection of relaxants
 - E. Additional injection droperidol
111. Patient 30 years after a road-transport failure complaints of the acute tahypno Ob-ly: a skin is pale, cyanosi Hypodermic emphysema in the region of thorax, stomach, right side of the neck. Auscultative: breathing on the right side is not conducted; pulse – 130/min., AP – 80/60 mm.mercury., CVP – 140 mm wt., FB – 30 /min., Ht – 0,27, Hb – 90 g/l. Subsequent therapy must include above all things:
- A. *punction of pleura cavity.
 - B. Urgent ALV
 - C. Massive infusion therapy of the crystalloid solutions
 - D. Infusion of dofamin, 2-5 mcg/cg/min
 - E. 100% oxygen
112. Patient has BP - 80/40 mm mercury, pulse - 120 per min, shock index for him:
- A. *120/80=1,5
 - B. 80+40)120=1
 - C. 80/120=0,67
 - D. 120/40=3
 - E. Not determined, as blood loss is unknown
113. Patient N., 47 years, treated in the hospital with the diagnosis: carbuncle of right kidney. Suddenly general condition deteriorated, body temperature 39.50 C, skin cold, humid, consciousness kept, expressed choking. Breath deep, noisy, 26/min. Pulse - 110/min., SC - 90/60 mm.mercury., oliguri Which complications we can think about?
- A. *Infectious-toxic shock
 - B. Vascular dystonia
 - C. Epilepsy
 - D. Anaphylactic shock
 - E. Orthostatic collapse
114. Patient, 40 years, with the trauma of both thighs is delivered from the scene of accident by a “passing transport”. Objectively: cyanosys, rubor of the lower half of the neck, tahypnoe, AP 60/40 mm mer st., HBA=120 /min, in lungs moist wheezes, diuresis – 20 ml/h., Nb 100 g/l. Which from the offered diagnoses most reliable?
- A. *Fatty embolism
 - B. Traumatic shock
 - C. Hemorrhagic shock
 - D. Pain shock
 - E. Tromboembolism
115. The patient 60 years is delivered in the department of intensive therapy with a diagnosis: bite of bee, anafilactic shock.. Which medicine will be primary and most effective?
- A. Adrenalin
 - B. Calcium the chloride
 - C. Prednizolon
 - D. Dimedrol
 - E. Suprastin

116. The patient 25 years is hospitalized in the surgical department with a diagnosis: penetrable wound of abdominal region. Objectively: it is excited, skin covers and visible mucous shells are pale; peripheral pulse of the weak filling, frequent, AP – 110/60 mm mercury Positive symptom of "desolation" of peripheral hypodermic vein Diuresis is lower How to characterize this state?
- The compensated shock
 - Preagonia
 - Circulating shock
 - Agony
 - Irreversible shock
117. The patient 36 years with ulcerous of gaster in anamnesis is hospitalized in the surgical department with complaints on vomiting by "coffee-grounds", diarrhea, moderately expressed thirst. Objectively: a skin is pale, covered by a death-damp, a tongue is dry, AP – 80/60 mm rt.st., HBA – 120/min., BF – 28/min., diuresis – 25 ml/h. Blood test: Era - 2,8 10¹²/l, Hb – 98 g/l. What will be most expedient in medical treatment:
- *solutions with colloid
 - 5% solution of glucose
 - Whole blood
 - Red corpuscles mass
 - Colloid solutions with red corpuscles mass
118. 118. Patient 48 years the second day in dpartment of intensive therapy concerning the acute front-partition heart attack of myocardium. During a review "wheezing" suddenly, non-permanent tonic constricting of muscles is marked, pupils are extended, pulse on carotis not palpitat What doctor have to do in the first place?
- Triple Safar method
 - Record of ECG
 - Cardial hit in the area of heart
 - Artificial respiration by the method of Silvester
 - Intracardial injection of adrenalin with an atropine
119. The patient entered the department with a diagnosis: acute intestinal impassability. Complaints: insignificant thirst, dizziness at an attempt to get up from a be At a review: patient apathetical, turgor is lowered, eyeballs are soft, tongue is dry with crack Pulse – 110 min., AP – 80 /60 mm of mer item, diuresis – 25 ml /h. Electrolyte composition: Na⁺ - 142 mmol/l, C⁺ - 4 mmol/l, glucose – 6 mmol/l, urea – 7 mmol/l. What variant of infusion is most expedient during operation?
- *Transfusion of crystalloid
 - Transfusion of solution of glucos
 - Transfusion of albumen.
 - Transfusion of native plasm
 - Transfusion of poliglucin.
120. The patient, 28 years, 2 hours ago fell down from the ground floor of hous Sopor, pale, there are the plural scratches of face, the lacerated hemorrhagic wounds on the left forearm. The closed break of the left shoulder and thigh. Pulse –110, Lc-10T/l, Hb – 100, AP – 90/40 mm of rt. item In the blood test: red corpuscles – 3,5 g/l. What infouziyniy serednic does not need to be used for medical treatment of shock?
- *5% solution of glucose
 - Solution of crystalloids
 - Solutions gelatin
 - Solutions of calcium
 - Solution of albumen
121. Anafilactic shock appeared at a patient. The state heavy and progressively gets wors HBA – 110 in a 1 minute, AP – 60/30 mm mercury. Prescribe medicine for the rescue of life of patient above all things?
- *Adrenalin.

- B. Chloride of calcium.
 - C. Prednizolon.
 - D. Dofamin.
 - E. Suprastin.
122. At a patient 20 years on a background the injection of vitamin B1 suddenly there was excitation, fear of death, falling of AP to 50 mm rt.st., hard breathing. Which of medicine it is necessary to inject firstly?
- A. *Adrenalin
 - B. Prednizolon
 - C. Calcium
 - D. Dimedrol
 - E. Eufilin
123. At a patient 60 years with the third day after an extirpation uterus acute insufficiency of breathing developed suddenly, a skin became at first cyanotic, and then ash-colored color. Tachypnoe, cough with bloody sputum, retrosternal pain. BP – 100/70 mm. mercury, HR – 120, BR – 32 in 1 min., CVP – 300 mm wt.col. What most reliable reason of worsening of the state of patient ?
- A. *Tromboemboliya of pulmonary artery
 - B. Bleeding
 - C. Pain shock
 - D. Hypostatic pneumonia
 - E. Heart attack of myocardium
124. At a patient in the ward of intensive therapy you marked appearance on the monitor of fibrillation of ventricule Your first actions?
- A. *To conduct defibrillation three times
 - B. To inject adrenalin
 - C. To inject a chloride
 - D. To begin the closed massage of heart
 - E. To inject lidocain
125. At a patient with the acute heart attack of myocardium best of all to warn relapsing fibrillation of ventricles with :
- A. cordaronum
 - B. lidocainum
 - C. ornidinum
 - D. *electrocardiostimulation
 - E. there is no right answer
126. At a patient with the acute heart attack of myocardium in the region of partition on a 5th day after the brief episode of loss of consciousness there is reduction of frequency of pulse to 32 in a minut BP - 80/40 mm Consciousness at the level of sopor. He immediately needs :
- A. to put right a craniotserebral hypothermia, to enter lasics, prednisoloni, tserebrolizin
 - B. to enter an atropine, eoufilin, to begin infouziyo of aloupenta
 - C. *to conduct urgent cardiostimoulation
 - D. all answers are faithful
 - E. there is no right answer
127. At a patient, carried to a 2 year ago the heart attack of myocardium, the acute decline of cholecystities planned cholecystectomy, signs of electric instability of myocardium . Actions of anaesthesiologist must include:
- A. injection of prednisoloni, lidocaini, hyperventilation, take the ECG
 - B. *injection of dopamini, after stabilisation of BP - nitroglycerine + infusion therapy under the control CVP, conducting of neurovegetative defence, take the ECG
 - C. injection of streptodecasol, stream infusion of reopoliglyocinum, injection of lidocainum, increase of dose of analgetics
 - D. correctly A) and C)
 - E. all answers are faithful

128. At a patient, that is found on medical treatment in the therapeutic department, the sudden stopping of circulation of blood happened. Medical personnel began the reanimation measure. Define the most rational way of injection of adrenalin for renewal of heart abbreviations in default of vein access:
- *To enter to a 3 ml solution of adrenalin in a trache
 - To enter to a 1 ml solution of adrenalin in muscle
 - To enter adrenalin in muscle, multiplying a dose in 3 times
 - The intracardial injection.
 - Adrenalin can be not entered
129. At a patient, that is found under the permanent electrocardiographic supervision, microwave fibrillation of myocardium and diagnosed clinical death developed. It is necessary to do:
- to inject the solution of calcium in cor
 - *to conduct high-voltage electric defibrillation
 - to inject solution of atropine in cor
 - to inject solution of adrenalin in cor
 - All answers are wrong
130. At the patient operated concerning the festering peritonitis caused by perforation of gastric ulcer, in a postoperation period appeared: high temperature, frequency of breathing 35/min., AP – 70/40 mm of mercury, diuresis -20 ml/h, temperature of body to 39 °C, leucocytosis. Transfusion during 12 hours 1,8 of a 0,9% solution of chlorure sodium and 0,8 of solution of reopoligluin did not improve general condition. Central vein pressure – 130 mm wt.st. For stabilization of hemodynamics will be optimum infusion:
- *Dopamin
 - Mezaton
 - Adrenalin
 - Noradrenalin
 - Ephedrine
131. At the ventilated patient with the edema of lungs at low pressure and septic shock intravenous infusion 7,5 mcg/kg/min dopamin will increase
- RaO₂, saturation of oxygen of the mixed vein blood, consumption of oxygen
 - diuresis
 - *cardiac systolic volume
 - right A) and B)
 - faithful all answers
132. In 2 hours after renewal of cardiac activity at a patient, that carried the sudden stop of heart on a background hemorrhagic shock (blood lost near 2,5 l) and is found on ALV, unstable hemorrhagia (AP – 80/40 – 90/60 mm of mercury, tachycardia) is marked, central vein pressure – 5 mm wt.st. It is related to:
- *By Hypovolume syndrome
 - By cardiac insufficiency
 - By the inadequate interchange of gases
 - Vasoplegia
 - By the inadequate anaesthetizing
133. In a clinic a patient with the traumatic tearing of both lower extremities off at the level of knee-joints is delivered. A patient is extremely inert, languid, pale, pulse 140 bpm, threadlike, AP 500. On both lower extremities there are the imposed plait. Bleeding at the receipt is not present. From the words of doctor of first-aid, lost about 3 litres of blood in place of event. What principal reason of heavy of the state of Patient?
- Acute hemorrhag
 - Pain shock.
 - Ishemia of extremities as a result of application of tourniquet
 - Fatty embolism
 - acute kidney insufficiency

134. In a clinic a patient with the traumatic tearing of both lower extremities off at the level of knee-joints is delivered. A patient is extremely inert, languid, pale, pulse 140 bpm, threadlike, AP 500. On both lower extremities there are the imposed plaits. Bleeding at the receipt is not present. From the words of doctor of first-aid, lost about 3 litres of blood in place of event. What principal reason of heavy of the state of Patient?
- *acute hemorrhage
 - Pain shock.
 - Ishemia of extremities as a result of application of tourniquet
 - Fatty embolism
 - acute kidney insufficiency
135. It is typical for:
- *Negative CVT
 - Erroneous puncture of artery
 - Right-side pneumothorax
 - Edema of lungs
 - Hypodermic emphysema
136. On a 4 day after incompatible (on a group) blood transfusion at a patient acutely reduced diuresis, anuria developed, the common state became worse acutely, arterial pressure rose. At laboratory research: creatinin plasma – 680 μmol/l, urea of plasma - 24 mmol/l. What illness and what stage of illness it follows to think about in the first place?
- Acute kidney insufficiency, anuria
 - Anaphylactic shock, acute kidney insufficiency, anuria
 - Hemotransfusion shock, postrenal acute kidney insufficiency, anuria
 - Posthemorrhagic acute kidney insufficiency, anuria
 - acute interstitial nephritis, postrenal anuria
137. Patient 20 years for verification of the functional state of kidneys the X-ray examination with v/v injection of contrast is conducted. At the end of injection the state of patient acutely became worse, the shortness of breath, hyperemia of skin, itch appeared. AP – 60/20 mm of mercury, HBA – 132/min. A similar research was conducted 3 months ago, such effects were not observed. What most reliable diagnosis?
- Medicinal anaphylactic shock
 - Acute kidney insufficiency
 - Thromboembolism of pulmonary artery
 - Stress on the conducted manipulation
 - Heart attack myocardium
138. Patient 38 years, native plasma was poured. At the end of infusion the state became worse: Patient confused, excited, cyanosis, hypersalivation. Breathing frequency 36 on 1 min., AP – 70/40 mm of mercury, whistling dry wheeze. Which from the following medicines must be injected firstly?
- *Adrenalin.
 - Eufilin.
 - Suprastin.
 - Noradrenalin.
 - Prednisolone.
139. Patient 40 years with the acute gastro-intestinal bleeding a canned blood was poured in a volume 400 ml after conducting of all tests on compatibility. After hemotransfusion the state of patient became worse, appeared head pains and pains in muscles at the temperature of body rose to 38,8. What can explain the state of patient?
- Pyrogenic reaction of middle heavy
 - By development of hemotransfusion shock
 - *Allergic reaction
 - By development of bacterial-toxic shock
 - By air embolism

140. Patient 40 years with the acute gastro - intestinal bleeding a canned blood was poured in a volume 400 ml after conducting of all tests on compatibility. After hemotransfusion the state of patient became worse, appeared head pains and pains in muscles at the temperature of body rose to 38,8 What can explain the state of patient?
- Pirogenic reaction of middle heavy
 - *By development of hemotransfusion shock
 - Allergic reaction
 - By development of bacterial-toxic shock
 - By air embolism
141. Patient 62 years the third day of presence in department of intensive therapy concerning the acute transmural heart attack of myocardium of front-partition localization. At night woked up from a suffocating cough, feeling of fear and trouble At a review: cyanosis, FB – 30 after 1 min., HBA – 132/ min., a rhythm is correct, tones of heart are deaf, accent II tone above a pulmonary artery, AP – 180/110 mm mercury. There is the loosened breathing above lungs with the far of moist wheezes in lower fate What probably became the reason of worsening of the state?
- *Edema of lungs
 - Embolism of pulmonary artery
 - The repeated heart attack myocardium
 - Hypertensive crisis
 - Attack of bronchial asthma
142. Patient L is hospitalized in gynecological department with the temperature of 39 degrees C, with complaints of pain in the bottom of stomach, vomit, diarrhea . Criminal abortion have been done 4 days before AP 80/60, breathing is difficult, psychosomatic excitation. Symptom of Schotkin-blumberg is positive Uterus is enlarged as on 9 weeks of pregnancy, limitedly mobile, painful Pus with blood appears Your Diagnosis?
- *septic shock
 - Perforation of uterus
 - Pelvic peritonitis
 - Acute appendicitis
 - Acute adnexia inflammation
143. Patient N., 28 years old 6 day after the complicated birth The clinical hematological signs of subacute disseminated intravascular coagulation syndrome developed after skin hemorrhage and uterine bleeding. The state of patient is very bad blood: Er-2,7 of T/l, Hb-78 of gm/l, CI - 0,93, L-4,7 of Gm/l, thrombocytes-88 of gm/l, time of blood clotting - 16 min, prothrombin time - 25 sec, ethanol test +, fibrinogen-1,4 gramme/l, What preparations should be prescribed ?
- *frozen plasma
 - Heparinum
 - Reopoliglycin
 - Cryoprecipitate
 - U-aminokapric acid
144. Patient N., 40 years, groom. In anamnesis there is an allergy to nonsteroidal antiinflammatory. After injection of antitetanus on a method Besredko concerning the hammered wound of right shin, through 20 minutes, there was an acute weakness, laboured breath, through 10 minutes, loss of consciousness What mechanism of development of anaphylactic form of illness?
- Sensitization to the albumen of horse whey
 - Low quality of horse whey
 - Breach of the technique of PPS injection
 - Presence in anamnesis of medical allergy
 - Infection of whey
145. Patient N., 40 years, groom. In anamnesis there is an allergy to nonsteroidal antiinflammatory. After injection of antytetanus on a method Besredko concerning the hammered wound of right shin, through 20 minutes, there was an acute weakness, laboured breath,

through 10 minutes, loss of consciousness. What mechanism of development of anaphylactic form of illness?

- A. *Sensitization to the albumen of horse whey
 - B. Low quality of horse whey
 - C. Breach of the technique of PPS injection
 - D. Presence in anamnesis of medical allergy
 - E. Infection of whey
146. Person 48 years, patient by the heart attack of myocardium, suddenly lost consciousness, breathing and palpitation. On ECG of high-wave fibrillation of ventricle. Conducted defibrillation. Did not pick up normal cardiac activity. What medicine needs to be entered for the rise of sensuality to defibrillation?
- A. *Amiodaron
 - B. Propranolon
 - C. Lidocain
 - D. Strofantin
 - E. Atropini sulfati
147. Pharmacological medicine, that diminish the (afterload) left ventricle at a patient with the acute heart attack of myocardium, are not included
- A. nitroglycerine
 - B. *strophantine
 - C. nitroprussid sodium
 - D. esmolol (brevibloc)
 - E. nifedipinum
148. Sick 46 years treated oneself in a therapeutic department with pneumonia of lower lobe of right lung. Planned antibacterial therapy - amoxiclav. After 40 min after intramuscular injection of duty dose, the patient felt dizziness, pain behind a breastbone. AT 60/40 mm Hg, pulse, - 120 a min., rhythmical. During examination of lungs: wheezes under both lung. Temperature is 38,5. What is worsening of the condition related to?
- A. *Anaphylactic shock
 - B. Infectious toxic shock
 - C. Collapse
 - D. Tromboembolia of pulmonary artery
 - E. Infectious shock
149. The patient 20 years old, delivered to ambulance department on the 2nd day of illness in a grave condition: temperature of body 39°C, symptoms of intoxication are expressed. On extremities, trunk, buttocks, present hemorrhagic rash as eczema with necrosis in the center. One day before cut his leg. Now has the wound in that place. In 2 hours the decline of AP is registered from 100/70 to 60/30 mm of Hg, diffused cyanosis. Application of prednisolon of 120 mg and reopolyglucin did not give any effect. What complication does it follow to think about?
- A. acute sub renal failure
 - B. *Septic shock
 - C. hypovolemic shock
 - D. Hemorrhagic shock
 - E. Respirator distress syndrom of adults
150. The patient 32 years have infusion of native plasma. At the end of infusion the state became worse: disorientation, cyanosis, excitation, appeared hypersalivation, tachypnoea, AP = 70/40 mm Hg, in lungs – the dissipated dry wheeze. What medicine must be injected firstly?
- A. *Adrenalin.
 - B. Suprastin.
 - C. Hidrocortizon.
 - D. Dopamin.
 - E. Eufilin.
151. To patient P., 50 years, with an unspecified ulcerous colitis with the purpose of correction of anaemia transfusion of self-group blood 500 ml A(II) the Rh(-) was conducted. A doctor went out

from a chamber after conducting of necessary tests before hemotransfusion. In 20 minutes he was quickly asked to the patient. Patient without consciousness. The cyanosis of upper body part. Irregular breathing with the selection of a plenty of foamy, with the admixtures of blood, phlegm. Pulse on peripheries and arterial pressure are not determined. Tones of heart are deaf, unrhythmical. An ampoule and transfusion system is empty. What complication arose up as a result of hemotransfusion?

- A. *Air embolism of pulmonary artery
 - B. Tromboembolism of pulmonary artery
 - C. Edema of lungs
 - D. Heart attack of myocardium
 - E. Syndrome of massive hemotransfusion
152. To the patient 45 years with suspicion on cholecystitis the rentgencontrast i/v is quickly injecte. Tahycardiya, arterial hypotension, cyanosis, shortness of breath appeared, acute swelling of veins of neck, extension of liver, CVT to 200 mm wt.st. acute insufficiency of what part of the cardial-vascular system is observed at a patient?
- A. *Right ventricle of heart
 - B. The left ventricle of heart
 - C. Both ventricles of heart
 - D. Vessels
 - E. Uneffective heart
153. A man 50 years of asymptomatic mixed goiter. At the first stage, it should appoint
- A. *only observation
 - B. thyroid hormones to suppress the function of cancer
 - C. propylthiouracil
 - D. subtotal thyroidectomy
 - E. radioiodine
154. In patient K, aged 26, noted a relapse of hyperthyroidism after medical treatment. Your tactics.
- A. *Surgical treatment
 - B. Continue medical treatment
 - C. Outpatient
 - D. Treatment is not required
 - E. Is no right answer
155. In patients after operations on the thyroid gland have complaints about the shortness of breath, lethargy, convulsions. What is the cause of these clinical manifestations?
- A. *lower calcium concentration
 - B. lower content of iodothyronine
 - C. increasing concentrations of glucose
 - D. increasing concentration of potassium
 - E. no right answer
156. On examination, the patient was 32 years reveal the formation of the left lobe of the thyroid gland size 4x6 cm, painless at palpation. What additional diagnostic method to assign?
- A. *Thyroid gland
 - B. Radiography of the neck
 - C. Doppler
 - D. Rheovasography
 - E. EEG
157. On examination, the patient was 32 years reveal the formation of the left lobe of the thyroid gland size 4x6 cm, painless at palpation. What analysis should be performed in order to clarify the diagnosis?
- A. *Thyroid hormones
 - B. Total blood
 - C. Urinalysis
 - D. Immunogram

- E. Protein fraction
158. Patient D, aged 39, admitted to the hospital with the diagnosis: diffuse toxic goiter. What study be done.
- A. *Investigation of iodine hormones in the blood serum
 - B. EFGDS
 - C. Is no right answer
 - D. Rheovasography
 - E. Doppler
159. Patient J., 57, was admitted to the surgical clinic with a diagnosis: euthyroid nodular goiter. Choose the correct treatment option.
- A. *resection of the thyroid gland with maximal preservation of healthy tissue and routine histological examination
 - B. enucleation
 - C. medication
 - D. subtotal resection of the thyroid gland
 - E. excision of the node with the routine histological examination
160. Patient K, aged 49, was admitted to the hospital with the diagnosis: diffuse toxic goiter. What study be done.
- A. *Scanning of the thyroid gland
 - B. EFGDS
 - C. Rheovasography
 - D. Doppler
 - E. There is no correct answer
161. Patient K., aged 45, lives in the area of iodine deficiency, was admitted to the clinic with complaints of enlarged thyroid gland. What is the most likely diagnosis in a patient?
- A. *goiter
 - B. acute strumitis
 - C. sporadic goiter
 - D. epidemic goiter
 - E. mass thyrotoxicosis
162. Patient M, 39 years old, was admitted to the hospital with the diagnosis: diffuse toxic goiter. What study be done.
- A. *Thyroid gland
 - B. EFGDS
 - C. Rheovasography
 - D. Doppler
 - E. Is no right answer
163. Patient M., aged 35, lives in the area of iodine deficiency, was admitted to the clinic with complaints of enlarged thyroid gland. What is the most likely diagnosis in a patient?
- A. *there is no right answer
 - B. acute strumitis
 - C. sporadic goiter
 - D. epidemic goiter
 - E. mass thyrotoxicosis
164. Patient O., aged 39, on the diffuse toxic goiter performed subtotal resection of the thyroid gland. One day the patient became restless, twitching of facial muscles appeared convulsive reduction of hands. Treatment.
- A. *the introduction of calcium chloride intravenously
 - B. introduction Seduxen
 - C. introduction of iodine
 - D. infusion therapy
 - E. introduction of calcium chloride oral

165. Patient O., aged 39, on the diffuse toxic goiter performed subtotal resection of the thyroid gland. One day the patient became restless, twitching of facial muscles appeared convulsive reduction of hands. What mated complication of surgery?
- *Removal of parathyroid glands
 - Iodine deficiency
 - Lack of thyroid tissue
 - Increased thyroid hormone
 - Increased parathyroid hormone
166. ?Patient S., 43, in the last 5 months of worry tearfulness, irritability, fatigue, progressive weight loss. On palpation the thyroid gland increased to III class., painless. Pulse 110-120 in minute, regular, blood pressure - 150/80. At USD: tissue homogeneous, tissue hypertrophy hyper. The most likely diagnosis
- *Toxic goiter
 - Hashimoto struma
 - Acute thyroiditis
 - nodular goiter
 - goiter De Quervain
167. Patient S., 43, in the last 5 months of worry tearfulness, irritability, fatigue, progressive weight loss. On palpation the thyroid gland increased to III class., painless. Pulse 110-120 in minute, regular, blood pressure - 150/80. At USD: tissue homogeneous, tissue hypertrophy hyper. The most likely diagnosis
- *there is no right answer
 - Hashimoto's thyroiditis
 - Acute thyroiditis
 - nodular goiter
 - goiter De Quervain
168. Patient S., 43, in the last 5 months of worry tearfulness, irritability, fatigue, progressive weight loss. On palpation the thyroid gland increased to III class., painless. Pulse 110-120 in minute, regular, blood pressure - 150/80. What additional diagnostic method to assign?
- *Thyroid gland
 - Radiography of the neck
 - Doppler
 - Reovazography
 - EEG
169. Patient S., 43, in the last 5 months of worry tearfulness, irritability, fatigue, progressive weight loss. On palpation the thyroid gland increased to III class., painless. Pulse 110-120 in minute, regular, blood pressure - 150/80. What analysis should be performed in order to clarify the diagnosis?
- *Total blood
 - Urinalysis
 - Thyroid hormones
 - Protein fraction
 - Immunogram
170. Patients after resection of the thyroid gland have cramps, Hvosstek and Trousseau symptoms. What complication is the patient?
- *gipoparatireosis
 - laryngeal nerve injury
 - residual effects of thyrotoxicosis
 - thyrotoxic crisis
 - hypothyroidism
171. Patients after resection of the thyroid having convulsions, symptoms by Chvostek and Trousseau. What a complication arose in a patient?
- *there is no right answer
 - laryngeal nerve injury

- C. residual effects of hyperthyroidism
 - D. thyrotoxic crisis
 - E. hypothyroidism
172. Patients after resection of the thyroid having convulsions, symptoms by Chvostek and Trousseau. What a complication is arose in a patient?
- A. *hypoparathyreosis
 - B. laryngeal nerve injury
 - C. residual effects of hyperthyroidism
 - D. thyrotoxic crisis
 - E. hypothyroidism
173. The patient complaints of excessive sweating, hand tremor, exophthalmos. The most likely diagnosis.
- A. *Strumit
 - B. Goiter
 - C. Tireodit
 - D. Thyrotoxicosis
 - E. Is no right answer
174. The patient diagnosed nodular nontoxic goiter. What operation is indicated the patient?
- A. *resection of the affected lobe with histological examination
 - B. conservative treatment of thyroxine
 - C. removal of the affected lobe, isthmus and central lymph node dissection
 - D. enucleation site
 - E. subtotal thyroidectomy
175. The patient diagnosed nodular nontoxic goiter. What operation is indicated the patient?
- A. *No right answer
 - B. conservative treatment of thyroxine
 - C. removal of the affected lobe, isthmus and central lymph node dissection
 - D. enucleation site
 - E. subtotal thyroidectomy
176. The patient diagnosed thyrotoxicosis. Which of the following symptoms suggests the pathology?
- A. *Exophthalmos
 - B. Peritoneal signs
 - C. Trophic ulcer
 - D. Limb gangrene
 - E. No right answer
177. The patient diagnosed thyrotoxicosis. Which of the following symptoms suggests the pathology?
- A. *Graefe symptom
 - B. Peritoneal signs
 - C. Trophic ulcer
 - D. Limb gangrene
 - E. No right answer
178. The patient diagnosed thyrotoxicosis. Which of the following symptoms suggests the pathology?
- A. *Mobius symptom
 - B. Peritoneal signs
 - C. Trophic ulcer
 - D. Limb gangrene
 - E. No right answer
179. The patient diagnosed thyrotoxicosis. Which of the following symptoms suggests the pathology?
- A. *Tachycardia
 - B. Peritoneal signs

- C. Trophic ulcer
 - D. Limb gangrene
 - E. No right answer
180. The patient diagnosed thyrotoxicosis. Which of the following symptoms suggests the pathology?
- A. *Tremor of the upper limbs
 - B. Peritoneal signs
 - C. Trophic ulcer
 - D. Limb gangrene
 - E. No right answer
181. The patient diagnosed with an aberrant goiter. Refine the definition of aberrant goiter.
- A. *cancer of the thyroid gland
 - B. metastases of thyroid cancer in the liver
 - C. atypical location of the thyroid gland
 - D. all true
 - E. all wrong
182. The patient diagnosed with autoimmune thyroiditis. Which of the following symptoms characteristic of this disease?
- A. *increase and thickening of the thyroid gland, hypothyroidism
 - B. increase and thickening of the thyroid gland, fever
 - C. increase and thickening of the thyroid gland, hypothyroidism, fever
 - D. increase and thickening of the thyroid gland,
 - E. thyrotoxicosis, fever
183. The patient diagnosed with nodular euthyroid goiter left lobe of the thyroid gland. What is the optimal treatment option.
- A. *hemistrumectomy or resection of the lobe of the thyroid gland
 - B. excision of the node with the routine histological examination
 - C. enucleation site
 - D. subtotal thyroidectomy
 - E. conservative treatment thyroidin
184. The patient lives in the area of endemic iodine. What can be used to prevent goitre?
- A. merkasalil
 - B. vaccination
 - C. iodine
 - D. improving the social life of the population
 - E. *iodination salt
185. The patient made thyreoidectomy. Which of the following complications may occur in a patient?
- A. *Pneumathemia
 - B. Onychomycosis
 - C. Trophic ulcer
 - D. Limb gangrene
 - E. No right answer
186. The patient made thyreoidectomy. Which of the following complications may occur in a patient?
- A. *Damage to the trachea
 - B. Onychomycosis
 - C. Trophic ulcer
 - D. Limb gangrene
 - E. No right answer
187. The patient made thyreoidectomy. Which of the following complications may occur in a patient?
- A. *Damage to the recurrent laryngeal nerve
 - B. Onychomycosis

- C. Trophic ulcer
 - D. Limb gangrene
 - E. No right answer
188. The patient made thyroidectomy. Which of the following complications may occur in a patient?
- A. *Bleeding from the wound
 - B. Onychomycosis
 - C. Trophic ulcer
 - D. Limb gangrene
 - E. No right answer
189. The patient S., 54 years old, diagnosed with goiter II degree. What is characteristic of the III degree of increase in thyroid gland?
- A. *visible swallowing
 - B. giant goiter
 - C. determined only by palpation
 - D. visible only when swallowing
 - E. determined only on ultrasound
190. The patient S., 61, suffering for 2 years nodular goiter, recently noted a rapid increase in the node. On scanning image identified a "cold node". Specify the most probable cause of this condition
- A. *node malignancy
 - B. cystic degeneration of the node
 - C. autoimmune
 - D. all true
 - E. hemorrhage site
191. The patient S., 61, suffering for 2 years nodular goiter, recently noted a rapid increase in the node. What method of diagnosis is the most informative?
- A. *scanning with radioactive iodine
 - B. X-ray of the neck
 - C. Doppler
 - D. Rheovasography
 - E. EEG
192. The patient underwent surgery on the thyroid gland. Which of the following post-operative complications can sports a patient?
- A. *No right answer
 - B. Ischemia of the upper extremities
 - C. Ischemia of lower extremities
 - D. Ileus
 - E. Gastric
193. The patient underwent surgery on the thyroid gland. Which of the following postoperative complications may be sports in the patient?
- A. *Hypocalcemia
 - B. Ischemia of the upper extremities
 - C. Ischemia of lower extremities
 - D. Ileus
 - E. Gastric
194. The patient underwent surgery on the thyroid gland. Which of the following postoperative complications may be sports in the patient?
- A. *Paresis of the recurrent laryngeal nerve
 - B. Ischemia of the upper extremities
 - C. Ischemia of lower extremities
 - D. Ileus
 - E. Gastric

195. The patient underwent surgery on the thyroid gland. Which of the following postoperative complications may be sports in the patient?
- *Thyrototoxic crisis
 - Ischemia of the upper extremities
 - Ischemia of lower extremities
 - Ileus
 - Gastric
196. The patient V., age 56, diagnosed with goiter of third degree. What is characteristic of the III degree of increase in thyroid gland?
- *visible without swallowing
 - giant goiter
 - determined only by palpation
 - visible only when swallowing
 - determined only on ultrasound
197. The patient was admitted with the diagnosis: diffuse toxic goiter. What operation is indicated the patient?
- *subtotal resection of the thyroid gland
 - thyroidectomy
 - hemistrumectomy
 - strumectomy
 - no right answer
198. The patient was admitted with the diagnosis: diffuse toxic goiter. What operation is indicated the patient?
- *No right answer
 - thyroidectomy
 - hemistrumectomy
 - strumectomy
 - no right answer
199. The patient was planned to study the thyroid gland with radioactive iodine-131. How much time should not use iodine and thyreostatics?
- *30 days
 - 50 days
 - 40 days
 - 10 days
 - 20 days
200. The patient was planned to study the thyroid gland with radioactive iodine-131. How much time should not use iodine and thyreostatics?
- *No right answer
 - 50 days
 - 40 days
 - 10 days
 - 20 days
201. The patient's 43 years revealed an increase in the left lobe of the thyroid gland. When scanning in this region found a hot site. Diagnosis.
- *nodular toxic goiter
 - diffuse non-toxic goiter
 - toxic goiter
 - multinodular toxic goiter
 - non-toxic nodular goiter
202. The patient's 60 years in the last 3 months has been rapidly increasing dense mass in the left lobe of the thyroid gland. Effects of hyperthyroidism is not. At thyroid scan revealed a cold junction. Preliminary diagnosis
- *thyroid cancer
 - lipoma of the thyroid gland

- C. cyst
 - D. metastasis of lung cancer
 - E. thyroid cyst
203. A Patient admitted to the clinic with a diagnosis: obliterating atherosclerosis of lower extremities, chronic arterial ischemia I stage. The most informative type of research vessels are:
- A. *Ultrasound examination
 - B. Rheovasography
 - C. Thermometry
 - D. Palpation identification of artery pulsation
 - E. Venogram
204. A patient admitted to the clinic with a diagnosis: obliterating atherosclerosis of lower extremities, chronic arterial ischemia I stage. The most informative type of research vessels are:
- A. *Arteriography
 - B. Rheovasography
 - C. Thermometry
 - D. Palpation identification of artery pulsation
 - E. Venogram
205. A patient admitted to the clinic with a diagnosis: obliterating atherosclerosis of lower extremities, chronic arterial ischemia I stage. The most informative type of research vessels are:
- A. *No right answer
 - B. Rheovasography
 - C. Thermometry
 - D. Palpation identification of artery pulsation
 - E. Venogram
206. A patient admitted with complaints of pain in the lower extremities during the passage of more than 1000 m. What is the stage of chronic arterial insufficiency in the patient?
- A. *I
 - B. II A
 - C. II B
 - D. III
 - E. IV
207. A patient admitted with complaints of pain in the lower extremities during the passage of 300 - 400 m. What is the stage of chronic arterial insufficiency in the patient?
- A. *II A
 - B. I
 - C. II B
 - D. III
 - E. IV
208. A patient admitted with complaints of pain in the lower extremities during the passage of 200 m. What is the stage of chronic arterial insufficiency is the patient?
- A. *II B
 - B. I
 - C. II A
 - D. III
 - E. IV
209. A patient admitted with complaints of pain at rest. What stage of chronic arterial insufficiency has the patient?
- A. *III
 - B. I
 - C. II A
 - D. II B
 - E. IV
210. A patient admitted with complaints of pain from intermittent claudication, and impotence. What is the diagnosis can be suspected in a patient?

- A. *Leriche syndrome
 - B. Obliterating endarteritis
 - C. Deep vein thrombosis leg
 - D. Iliac femoral thrombosis
 - E. Coarctation of aorta
211. A patient admitted with complaints of pain in the muscles of the buttocks and waist. What is the diagnosis can be suspected in a patient?
- A. *Leriche syndrome
 - B. Obliterating endarteritis
 - C. Deep vein thrombosis leg
 - D. Iliac femoral thrombosis
 - E. Coarctation of aorta
212. At examination the patient was diagnosed the absence pulse on femoral arteries. What is the diagnosis can be suspected in a patient?
- A. *Leriche syndrome
 - B. Obliterating endarteritis
 - C. Deep vein thrombosis leg
 - D. Iliac femoral thrombosis
 - E. Coarctation of aorta
213. The patient 53 years old admitted to hospital with suspected atherosclerosis arteries of lower extremities. Differential diagnosis should be with:
- A. *Obliterative endarteritis
 - B. Deep vein thrombosis of lower leg
 - C. Iliac vein thrombosis
 - D. Varicosity
 - E. Thrombophlebitis superficial veins
214. The patient 53 years old admitted to hospital with suspected atherosclerosis of arteries of lower extremities. Differential diagnosis should be with:
- A. *Diabetic angiopathy
 - B. Deep vein thrombosis of lower leg
 - C. Iliac vein thrombosis
 - D. Varicosity
 - E. Thrombophlebitis superficial veins
215. The patient aged 53 years admitted to hospital with suspected atherosclerosis of arteries of lower extremities. Differential diagnosis should be with:
- A. *Sciatica
 - B. Deep vein thrombosis of lower leg
 - C. Thrombosis of iliac vein
 - D. Varicosity
 - E. Thrombophlebitis superficial veins
216. The patient admitted to hospital with complaints of pain at rest. What should be used to block pain?
- A. *Epidural block
 - B. No-shpa
 - C. Trental
 - D. Rheopolyglucin
 - E. Solcosery
217. The patient admitted to hospital with complaints of pain at rest. What should be used to block pain?
- A. *Paravertebral sympathetic blockade
 - B. No shpa
 - C. Trental
 - D. Rheopolyglucine
 - E. Solcoseryl

218. Patient is in hospital with diagnosis: obliterating atherosclerosis of arteries lower extremities, chronic arterial insufficiency II stage. To improve the rheological properties of blood should be used:
- A. *Rheopoliglucin
 - B. Seduksen
 - C. Actovegin
 - D. Niacin
 - E. Papaverine
219. Patient is in hospital with a diagnosis: arterial occlusive disease of the lower extremities, chronic arterial insufficiency II stage. To improve the rheological properties of blood should be used:
- A. *Trental
 - B. Seduksen
 - C. Actovegin
 - D. Niacin
 - E. Papaverine
220. Patient is in hospital with a diagnosis: obliterating atherosclerosis of arteries lower extremities, chronic arterial insufficiency II stage. To remove vasospasm should be used:
- A. *Papaverine
 - B. Rheopoliglikin
 - C. Seduksen
 - D. Actovegin
 - E. Niacin
221. Patient to detect arterial ischemia need to be functional tests:
- A. *Oppel
 - B. Troyanov
 - C. Sidorenko
 - D. Stepanova
 - E. Kokket
222. Patient to detect arterial ischemia need to be functional tests:
- A. *Goldflam
 - B. Troyanov
 - C. Sidorenko
 - D. Stepanova
 - E. Kokket
223. Patient to detect arterial ischemia need to be functional tests:
- A. *Panchenko
 - B. Troyanov
 - C. Sidorenko
 - D. Stepanova
 - E. Kokket
224. The patient 47 years old complained on pain in the calf muscles during walking. What is this symptom:
- A. *Intermittent claudication
 - B. Troyanov
 - C. Oppel
 - D. Panchenko
 - E. Kokket
225. At doppler ultrasound study in the patients revealed atherosclerotic changes in arteries. What method of diagnosis must be pursued to clarify the localization process?
- A. *Arteriography
 - B. Thermometry
 - C. Radiography of limbs
 - D. Radiography of the chest cavity

- E. ECG
226. The patient admitted to hospital with a diagnosis: embolism the left popliteal artery. What diseases can cause embolism?
- A. *Rheumatic heart disease
 - B. Acute pancreatitis
 - C. Acute cholecystitis
 - D. Ulcer
 - E. Obliterate endarteritis
227. The patient admitted to hospital with a diagnosis: embolism the left popliteal artery . What is the most probable cause of embolism?
- A. *Myocardial infarction
 - B. Acute pancreatitis
 - C. Acute cholecystitis
 - D. Ulcer
 - E. Obliterate endarteritis
228. The patient admitted to hospital with a diagnosis: embolism the right popliteal artery . What is the most probable cause of embolism?
- A. *Cardiac aneurysm
 - B. Acute pancreatitis
 - C. Acute cholecystitis
 - D. Ulcer
 - E. Obliterate endarteritis
229. The patient admitted to hospital with a diagnosis: embolism the right popliteal artery . What is the most probable cause of embolism?
- A. *Aneurysm of femoral artery
 - B. Acute pancreatitis
 - C. Acute cholecystitis
 - D. Ulcer
 - E. Obliterate endarteritis
230. The patient admitted to hospital with a diagnosis: embolism the left popliteal artery . What is the most probable cause of embolism?
- A. *Septic endocarditis
 - B. Acute pancreatitis
 - C. Acute cholecystitis
 - D. Ulcer
 - E. Obliterate endarteritis
231. The patient admitted to hospital with suspected embolism the left popliteal artery. What is the symptom will testify in favor of embolism?
- A. *Severe pain in the limbs
 - B. Filling saphenous veins
 - C. Trophic ulcer leg
 - D. Varicose saphenous veins
 - E. Reticular varicose
232. *The patient admitted to hospital with suspected embolism right popliteal artery. What is the symptom will testify in favor of embolism?
- A. *Cold extremities
 - B. Filling saphenous veins
 - C. Trophic ulcer leg
 - D. Varicose saphenous veins
 - E. Reticular varicose
233. The patient admitted to hospital with suspected embolism the right popliteal artery. What is the symptom will testify in favor of embolism?
- A. *Acute weakness in the limbs
 - B. Filling saphenous veins

- C. Trophic ulcer leg
 - D. Varicose saphenous veins
 - E. Reticular varicose
234. The patient admitted to hospital with suspected embolism left popliteal artery. What is the symptom will testify in favor of embolism?
- A. *Pale skin limbs
 - B. Filling saphenous veins
 - C. Trophic ulcer leg
 - D. Varicose saphenous veins
 - E. Reticular varicose
235. The patient admitted to hospital with suspected embolism, right femoral artery. What is the symptom will testify in favor of embolism?
- A. *The deterioration of the picture subcutaneous veins of the affected limb
 - B. Filling saphenous veins
 - C. Trophic ulcer leg
 - D. Varicose saphenous veins
 - E. Reticular varicose
236. The patient admitted to hospital with suspected embolism the right femoral artery. What is the symptom will testify in favor of embolism?
- A. *Changing the surface sensitivity on the affected limb
 - B. Filling saphenous veins
 - C. Trophic ulcer leg
 - D. Varicose saphenous veins
 - E. Reticular varicose
237. The patient admitted to hospital with suspected embolism the right femoral artery. What is the symptom will testify in favor of embolism?
- A. *Changing a deep sensitivity to the affected limb
 - B. Filling saphenous veins
 - C. Trophic ulcer leg
 - D. Varicose saphenous veins
 - E. Reticular varicose
238. In the patient admitted to hospital with suspected embolism the right femoral artery. What is the symptom will testify in favor of embolism?
- A. *The disappearance of pulsation with the level of the femoral artery
 - B. Filling saphenous veins
 - C. Trophic ulcer leg
 - D. Varicose saphenous veins
 - E. Reticular varicose
239. In the patient admitted to hospital with suspected embolism the right popliteal artery. What is the symptom will testify in favor of embolism?
- A. *The disappearance of pulsation with the level of the popliteal artery
 - B. Filling saphenous veins
 - C. Trophic ulcer leg
 - D. Varicose saphenous veins
 - E. Reticular varicose
240. In the patient zone of ischemia grabs both legs and lower abdomen. What are level of occlusion?
- A. *Bifurcation of the aorta
 - B. Iliac arteries
 - C. Femoral artery
 - D. Popliteal artery
 - E. Arteries foot
241. In the patient zone of ischemia captures the lower extremity to the inguinal ligament. What are level of occlusion?

- A. *Iliac arteries
 - B. Bifurcation of the aorta
 - C. Femoral artery
 - D. Popliteal artery
 - E. Arteries foot
242. In the patient zone of ischemia captures the lower extremity to the middle third of the thigh. What are level of occlusion?
- A. *Femoral artery
 - B. Bifurcation of the aorta
 - C. Iliac arteries
 - D. Popliteal artery
 - E. Arteries foot
243. In the patient zone of ischemia captures the lower extremity to the knee joint. What are level of occlusion?
- A. *Popliteal artery
 - B. Bifurcation of the aorta
 - C. Iliac arteries
 - D. Femoral artery
 - E. Arteries foot
244. In the patient zone of ischemia captures the whole hand. What are level of occlusion?
- A. *Subclavian artery
 - B. Axillary artery
 - C. Brachial artery
 - D. Ulnar artery
 - E. Arteries hand
245. The patient zone of ischemia grabs his hand to the upper third of the shoulder. What are level of occlusion?
- A. *Axillary artery
 - B. Subclavian artery
 - C. Brachial artery
 - D. Ulnar artery
 - E. Arteries hand
246. In the patient zone of ischemia grabs his hand to the middle third of the shoulder. What are level of occlusion?
- A. *Brachial artery
 - B. Axillary artery
 - C. Subclavian artery
 - D. Ulnar artery
 - E. Arteries hand
247. In the patient zone of ischemia grabs his hand to the elbow joint. What are level of occlusion?
- A. *Ulnar artery
 - B. Axillary artery
 - C. Subclavian artery
 - D. Brachial artery
 - E. Arteries hand
248. A patient admitted to hospital complaining of a sharp intense pain in the limbs. This symptom is typical for
- A. *Embolism
 - B. Thrombosis
 - C. Atherosclerotic lesions
 - D. Varicose
 - E. Postthrombotic syndrome

249. A patient admitted to hospital complaining of pain in the limbs with a gradual increase in intensity. This symptom is typical for
- A. *Thrombosis
 - B. Embolism
 - C. Atherosclerotic lesions
 - D. Varicose
 - E. Postthrombotic syndrome
250. The patient admitted to hospital with a stab wound femoral artery. Which type of injury is this damage?
- A. *Open injury
 - B. Closed injury
 - C. Mixed damage
 - D. Combined damage
 - E. Fire damage
251. The patient was admitted to hospital with a knife wound femoral artery. Which type of injury is this damage?
- A. *Open injury
 - B. Closed injury
 - C. Mixed damage
 - D. Combined damage
 - E. Fire damage
252. The patient admitted to hospital with chopped wound in the femoral artery. Which type of injury is this damage?
- A. *Open injury
 - B. Closed injury
 - C. Mixed damage
 - D. Combined damage
 - E. Fire damage
253. The patient admitted to hospital with a shattered wound in the femoral artery. Which type of injury is this damage?
- A. *Open injury
 - B. Closed injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
254. The patient admitted to hospital with a gunshot wound in the femoral artery. Which type of injury is this damage?
- A. *Open injury
 - B. Closed injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
255. The patient admitted to hospital with external bleeding in the femoral artery. Which type of injury is this damage?
- A. *Fresh wounds
 - B. Closed injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
256. The patient was admitted to hospital in a state of shock and damage in the femoral artery in history. Which type of injury is this damage?
- A. *Fresh wounds
 - B. Closed injury
 - C. Mixed damage

- D. Combined damage
 - E. Through damage
257. The patient was admitted to hospital with gangrene and limb damage in the femoral artery in history. Which type of injury is this damage?
- A. *Fresh wounds
 - B. Closed injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
258. The patient admitted to hospital pulsating hematoma and injuries to the femoral artery in history. Which type of injury is this damage?
- A. *Complicated wounds
 - B. Closed injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
259. The patient was admitted to hospital with bruising and damage to suppuration in the femoral artery in history. Which type of injury is this damage?
- A. *Complicated wounds
 - B. Closed injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
260. The patient admitted to hospital with a blunt injury in the femoral artery in history. Which type of injury is this damage?
- A. *Closed injury
 - B. Open injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
261. The patient admitted to hospital with a compression of the femoral artery in history. Which type of injury is this damage?
- A. *Closed injury
 - B. Open injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
262. The patient admitted to the hospital with damage to only the femoral artery. Which type of injury is this damage?
- A. *Isolated damage
 - B. Open injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
263. The patient admitted to the hospital with damage to the femoral artery and internal organs. Which type of injury is this damage?
- A. *Combined injuries
 - B. Joint damage
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
264. The patient admitted to the hospital with damage to the popliteal artery in the first day after injury. To what this type of injury is damage?
- A. *Recent damage

- B. Open injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
265. The patient admitted to the hospital with damage to the popliteal artery on the second day after injury. To what this type of injury is damage?
- A. *Recent damage
 - B. Open injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
266. The patient admitted to hospital with damage to the popliteal artery on the fourth day after injury. To what this type of injury is damage?
- A. *Complicated injuries
 - B. Open injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
267. The patient admitted to the hospital with damage to the popliteal artery on the seventh day after injury. To what this type of injury is damage?
- A. *Complicated injuries
 - B. Open injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
268. The patient admitted to the hospital with damage to the popliteal artery in the second week after injury. To what this type of injury is damage?
- A. *Complicated injuries
 - B. Open injury
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
269. A patient admitted to hospital with clinical symptoms of external bleeding in axillary artery. To whom this type of injury is damage?
- A. *Open injury
 - B. Complicated injuries
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
270. A patient admitted to hospital with clinical symptoms of external bleeding in axillary artery. To whom this type of injury is damage?
- A. *Open injury
 - B. Complicated injuries
 - C. Mixed damage
 - D. Combined damage
 - E. Through damage
271. A patient admitted to hospital with knife wounds in the superficial femoral artery. Which research method can give the most accurate information?
- A. *Vascular ultrasound
 - B. Thermometry
 - C. Radiography of the lower extremity
 - D. Radiography of abdominal
 - E. Rheovasography

272. A patient admitted to hospital with knife wounds in the superficial femoral artery. Which research method can give the most accurate information?
- A. *Angiography
 - B. Thermometry
 - C. Radiography of the lower extremity
 - D. Radiography of abdominal
 - E. Rheovasography
273. A patient admitted to hospital with knife wounds in the femoral artery. Which research method can give the most accurate information?
- A. *There is no correct answer
 - B. Thermometry
 - C. Radiography of the lower extremity
 - D. Radiography of abdominal
 - E. Rheovasography
274. A patient admitted to hospital with a diagnosis: Varicose veins the left lower extremity. At the examination revealed only varicose saphenous veins of legs without edema. What stage of varicose veins is in a patient?
- A. *I
 - B. II A
 - C. II B
 - D. III
 - E. IV
275. A patient admitted to hospital with a diagnosis: Varicose veins left lower extremity. At the examination revealed varicose saphenous veins of lower leg with swelling and pasty. What stage of varicose veins is in a patient?
- A. *II A
 - B. I
 - C. II B
 - D. III
 - E. IV
276. A patient admitted to hospital with a diagnosis: Varicose veins left lower extremity. At the examination revealed varicose saphenous veins with leg edema, pasty, and induration of the skin ulcer in the lower third of the leg. What stage of varicose veins is in a patient?
- A. *III
 - B. II A
 - C. I
 - D. II B
 - E. IV
277. A patient admitted to hospital with a diagnosis: Varicose veins left lower limb, chronic venous insufficiency I degree. What kind of treatment the patient is the best?
- A. *Elastic compression
 - B. Surgical treatment
 - C. Antihypertensive therapy
 - D. Anticoagulant therapy
 - E. Anticholesterol therapy
278. A patient admitted to hospital with a diagnosis: Varicose veins left lower limb, chronic venous insufficiency II degree. What kind of treatment the patient is the best?
- A. *Surgical treatment
 - B. Elastic compression
 - C. Antihypertensive therapy
 - D. Anticoagulant therapy
 - E. Anticholesterol therapy
279. A patient admitted to hospital with a diagnosis: Varicose veins left lower limb, chronic venous insufficiency III degree. What kind of treatment the patient is the best?

- A. *Surgical treatment
 - B. Elastic compression
 - C. Antihypertensive therapy
 - D. Anticoagulant therapy
 - E. Anticholesterol therapy
280. A patient admitted to hospital with a diagnosis: Varicose veins left lower limb, chronic venous insufficiency of II degree. What drug with venotonics properties should be appoint?
- A. *Detralex
 - B. Aspirin
 - C. Pentoksifilin
 - D. Heparin
 - E. Warphrin
281. A patient admitted to hospital with a diagnosis: Varicose veins left lower limb, chronic venous insufficiency of II degree. Which drug with venotonics properties should be appoint?
- A. *Phlebodia
 - B. Aspirin
 - C. Pentoksifilin
 - D. Heparin
 - E. Warphrin
282. A patient admitted to hospital with a diagnosis: Varicose veins left lower limb, chronic venous insufficiency of II degree. Which drug with venotonics properties should be appoint?
- A. *Detralex
 - B. Aspirin
 - C. Pentoksifilin
 - D. Heparin
 - E. Warphrin
283. A patient admitted to hospital with a diagnosis: Varicose veins left lower limb, chronic venous insufficiency of II degree. Which drug with antiplatelet properties should be designated?
- A. *Aspirin
 - B. Detralex
 - C. Pentoksifilin
 - D. Heparin
 - E. Warphrin
284. A patient admitted to hospital with a diagnosis: Varicose veins, right lower extremity, chronic venous insufficiency of II degree. Which drug with antiplatelet properties should be designated?
- A. *Cardimagnil
 - B. Detralex
 - C. Pentoksiphilin
 - D. Heparin
 - E. Warphrin
285. The patient admitted to the hospital with a diagnosis: Varicose disease of the right lower limb, chronic venous insufficiency III degree. Which of the following methods gives the most accurate information about the state of the venous system?
- A. *Vascular ultrasound
 - B. Radiography of the affected limb
 - C. Rheovasography
 - D. Thermometry
 - E. ECG
286. The patient admitted to the hospital with a diagnosis: Varicose disease of the right lower limb chronic venous insufficiency III degree. Which of the following methods gives the most accurate information about the state of the venous system?
- A. *Phlebography
 - B. Radiography of the affected limb

- C. Rheovasography
 - D. Thermometry
 - E. ECG
287. The patient admitted to the hospital with a diagnosis: Varicose disease of the right lower limb chronic venous insufficiency III degree. Which of the following methods gives the most accurate information about the state of communicative veins?
- A. *Vascular ultrasound
 - B. Radiography of the affected limb
 - C. Rheovasography
 - D. Thermometry
 - E. ECG
288. The patient admitted to the hospital with a diagnosis: Varicose disease of the right lower limb chronic venous insufficiency III degree. Which of the following methods gives the most accurate information about the state of communicative veins?
- A. *No right answer
 - B. Radiography of the affected limb
 - C. Rheovasography
 - D. Thermometry
 - E. ECG
289. The patient admitted to the hospital with a diagnosis: Varicose disease of the right lower limb chronic venous insufficiency III degree. Which of the following methods gives the most accurate information about the state of the venous system?
- A. *Flebotometry
 - B. Radiography of the affected limb
 - C. Rheovasography
 - D. Thermometry
 - E. ECG
290. The patient admitted to the hospital with a diagnosis: Varicose disease of the left lower limb, chronic venous insufficiency of Article III. Which of the following methods gives the most accurate information about the state of the venous system?
- A. *Functional Tests
 - B. Radiography of the affected limb
 - C. Rheovasography
 - D. Thermometry
 - E. ECG
291. The patient admitted to hospital with a diagnosis: Varicose disease, right lower extremity, chronic venous insufficiency III degree. Which diseases should be differentiate this disease?
- A. *Congenital arteriovenous fistula
 - B. Diabetic angiopathy
 - C. Atherosclerosis obliterans
 - D. Obliterative endarteritis
 - E. Raynaud's disease
292. The patient admitted to hospital with a diagnosis: Varicose disease, right lower extremity, chronic venous insufficiency III degree. Which diseases should be differentiate this disease?
- A. *Obtained arteriovenous fistula
 - B. Diabetic angiopathy
 - C. Atherosclerosis obliterans
 - D. Obliterative endarteritis
 - E. Raynaud's disease
293. The patient admitted to hospital with a diagnosis: Varicose disease, right lower extremity, chronic venous insufficiency III degree. Which diseases should be differentiate this disease?
- A. *Venous angiodysplasias
 - B. Diabetic angiopathy
 - C. Atherosclerosis obliterans

- D. Obliterative endarteritis
 - E. Raynaud's disease
294. The patient admitted to hospital with a diagnosis: Varicose disease, right lower extremity, chronic venous insufficiency III degree. Which diseases should be differentiate this disease?
- A. *No right answer
 - B. Diabetic angiopathy
 - C. Atherosclerosis obliterans
 - D. Obliterative endarteritis
 - E. Raynaud's disease
295. The patient admitted to hospital with a diagnosis: Varicose disease left lower limb, chronic venous insufficiency II drgree. What is a contraindication to surgical treatment?
- A. *Obstruction of deep veins
 - B. Chronic bronchitis
 - C. Past history of pneumonia
 - D. Past history of angina
 - E. Cholelithiasis
296. The patient admitted to hospital with a diagnosis: Varicose disease left lower limb, chronic venous insufficiency II degree. What is a contraindication to surgical treatment?
- A. *Angina
 - B. Chronic bronchitis
 - C. Past history of pneumonia
 - D. Past history of angina
 - E. Cholelithiasis
297. The patient admitted to hospital with a diagnosis: Varicose disease left lower limb, chronic venous insufficiency II degree. What is a contraindication to surgical treatment?
- A. *Heart failure
 - B. Chronic bronchitis
 - C. Past history of pneumonia
 - D. Past history of angina
298. The patient complains on burning pain in the limbs and the presence of painful dense strand of progress varicose veins in the leg. What is the most likely diagnosis in a patient?
- A. *Thrombophlebitis of subcutaneous veins
 - B. Deep vein thrombosis
 - C. Obliterating atherosclerosis
 - D. Occlusive disease
 - E. Diabetic angiopathy
299. The patient complains of burning pain in the limbs and the presence of painful dense strand of progress varicose veins in the leg with the transition to the lower third of the thigh. What is the most likely diagnosis in a patient?
- A. *Ascending thrombophlebitis of subcutaneous veins
 - B. Deep vein thrombosis
 - C. Obliterating atherosclerosis
 - D. Occlusive disease
 - E. Diabetic angiopathy
300. The patient complains of burning pain in the limbs and the presence of painful dense strand of progress varicose veins in the leg with the transition to the lower and middle third of the thigh. What is the most likely diagnosis in a patient?
- A. *Ascending thrombophlebitis of subcutaneous veins
 - B. Deep vein thrombosis
 - C. Obliterating atherosclerosis
 - D. Occlusive disease
 - E. Diabetic angiopathy

301. The patient complains of burning pain in the limbs and the presence of painful dense strand of progress varicose veins on the back of the tibia. What is the most likely diagnosis in a patient?
- *Small saphenous vein thrombophlebitis
 - Deep vein thrombosis
 - Obliterating atherosclerosis
 - Occlusive disease
 - Diabetic angiopathy
302. The patient complains on frequent thrombophlebitis in the zone of varicose great saphenous vein. What is the most likely diagnosis?
- *Migrating thrombophlebitis
 - Ascending thrombophlebitis
 - Deep vein thrombosis
 - Postthrombotic syndrome
 - Erysipelas
303. The patient complains on frequent thrombophlebitis in the zone of varicose great saphenous vein. What is the most likely diagnosis?
- *No right answer
 - Ascending thrombophlebitis
 - Deep vein thrombosis
 - Postthrombotic syndrome
 - Erysipelas
304. 304. The patient admitted to hospital with a diagnosis: Varicose veins left lower extremity. Acute ascending thrombophlebitis of subcutaneous veins. Tactics?
- *Surgical treatment
 - Conservative treatment
 - Physiotherapy
 - Sanatorium treatment
 - Treatment is not required
305. The patient admitted to hospital with a diagnosis: Varicose saphenous veins left lower extremity. Acute ascending thrombophlebitis of subcutaneous veins. Tactics?
- *No right answer
 - Conservative treatment
 - Physiotherapy
 - Sanatorium treatment
 - Treatment is not required
306. The patient underwent surgery for acute thrombophlebitis of subcutaneous veins. Which of the following drugs should be appoint after surgery?
- *Ciprinol
 - Vitamin C
 - Vitamin
 - Atenolol
 - Vasilip
307. The patient underwent surgery for acute thrombophlebitis of subcutaneous veins. Which of the following drugs should appoint after surgery?
- *Dikloberl
 - Vitamin C
 - Vitamin
 - Atenolol
 - Vasilip
308. The patient underwent surgery for acute thrombophlebitis of subcutaneous veins. Which of the following drugs should appoint after surgery?
- *Detralex
 - Vitamin C

- C. Vitamin
 - D. Atenolol
 - E. Vasilip
309. The patient underwent surgery for acute thrombophlebitis of subcutaneous veins. How long a patient should be advised to use elastic compression?
- A. *3 months.
 - B. 1 month.
 - C. 1 year
 - D. 6 months.
 - E. 2 weeks
310. The patient underwent surgery for acute thrombophlebitis of subcutaneous veins. How long a patient should be advised to use elastic compression?
- A. *There is no correct answer.
 - B. 1 month.
 - C. 1 year
 - D. 6 months.
 - E. 2 weeks
311. The patient complains on pain in the right leg, increases with foot movements. What is most likely diagnosis?
- A. *Thrombosis of the popliteal vein
 - B. Thrombosis of the femoral vein
 - C. Thrombosis of the iliac vein
 - D. Thrombosis of the inferior vena cava
 - E. Vein thrombosis aksilyarnoy
312. The patient complains on pain in the right leg, increases with foot movements. What research method is most reliable for further diagnosis?
- A. *Vascular ultrasound
 - B. Radiography of the affected limb
 - C. Ultrasonography of the abdomen
 - D. Radiography of the chest cavity
 - E. ECG
313. The patient complains on pain in the right leg, increases with foot movements. What research method is most reliable for further diagnosis?
- A. *Phlebography
 - B. Radiography of the affected limb
 - C. Ultrasonography of the abdomen
 - D. Radiography of the chest cavity
 - E. ECG
314. The patient complains on pain in the right leg and thigh, reinforced at moving foot and the knee joint. What is most likely diagnosis?
- A. *Thrombosis of superficial femoral vein
 - B. Thrombosis of the popliteal vein
 - C. Thrombosis of the iliac vein
 - D. Thrombosis of the vena cava inferior
 - E. Thrombosis Axillary vein
315. The patient complains on pain in the right leg hip, increases with movements in the foot and the knee joint. What research method is most reliable for further diagnosis?
- A. *Vascular ultrasound
 - B. Radiography of the affected limb
 - C. Ultrasonography of the abdomen
 - D. Radiography of the chest cavity
 - E. ECG
316. The patient complains on pain in the right leg hip, increases with movements in the foot and the knee joint. What research method is most reliable for further diagnosis?

- A. *Phlebography
 - B. Radiography of the affected limb
 - C. Ultrasonography of the abdomen
 - D. Radiography of the chest cavity
 - E. ECG
317. The patient complains on pain in the right leg and thigh, reinforced at moving foot and the knee joint. There is hypercyanotic color skin limbs. What is most likely diagnosis?
- A. *Thrombosis of common femoral vein
 - B. Thrombosis of the popliteal vein
 - C. Thrombosis of the iliac vein
 - D. Thrombosis of the inferior vena cava
 - E. Thrombosis Axyllary vein
318. The patient complains on pain in the right leg and thigh, reinforced at moving foot and the knee joint. There is hypercyanotic color skin limbs. What research method is most reliable for further diagnosis?
- A. *Phlebography
 - B. Radiography of the affected limb
 - C. Ultrasonography of the abdomen
 - D. Radiography of the chest cavity
 - E. ECG
319. The patient complains on pain in the right leg and thigh, reinforced at moving foot and the knee joint. There is hypercyanotic color skin limbs. What research method is most reliable for further diagnosis?
- A. *Vascular ultrasound
 - B. Radiography of the affected limb
 - C. Ultrasonography of the abdomen
 - D. Radiography of the chest cavity
 - E. ECG
320. The patient complains on pain in the right leg and thigh, reinforced at moving foot and the knee joint. There is hypercyanotic color skin limbs. Swelling of limbs throughout and on the buttocks What is most likely diagnosis?
- A. *Thrombosis of the iliac-femoral segment
 - B. Thrombosis of the popliteal vein
 - C. Thrombosis of the iliac vein
 - D. Thrombosis of the inferior vena cava
 - E. Thrombosis Axyllary vein
321. The patient complains on pain in the right leg and thigh, reinforced at moving foot and the knee joint. There is hypercyanotic color skin limbs. Swelling of limbs throughout and on the buttocks. What research method is most reliable for further diagnosis?
- A. *Vascular ultrasound
 - B. Radiography of the affected limb
 - C. Ultrasonography of the abdomen
 - D. Radiography of the chest cavity
 - E. ECG
322. The patient admitted to the hospital with a diagnosis deep vein thrombosis left lower extremity. The patient suddenly began to worry shortness of breath, retrosternal pain. What complication can be suspected in a patient?
- A. *Pulmonary embolism
 - B. Superficial thrombophlebitis
 - C. Ulcer
 - D. Pharyngitis
 - E. Pleurisy

323. The patient admitted to the hospital with a diagnosis deep vein thrombosis left lower extremity. The patient suddenly began to worry shortness of breath, retrosternal pain. What method diagnosis should be used to refine the diagnosis?
- A. *ECG
 - B. Reovazography
 - C. Densitometry
 - D. Ultrasound of internal organs
 - E. Ultrasound vascular limb
324. The patient admitted to the hospital with a diagnosis deep vein thrombosis left lower extremity. The patient suddenly began to worry shortness of breath, pain with localized behind the breastbone, a feeling of fear. What complication can be suspected in a patient?
- A. *Pulmonary embolism
 - B. Superficial thrombophlebitis
 - C. Ulcer
 - D. Pharyngitis
 - E. Pleurisy
325. The patient admitted to the hospital with a diagnosis deep vein thrombosis left lower extremity. The patient suddenly began to worry shortness of breath, retrosternal pain. What method diagnosis should be used to refine the diagnosis?
- A. *Radiography of the chest
 - B. Reovazogrifiya
 - C. Densitometry
 - D. Ultrasound of internal organs
 - E. Ultrasound vascular limb
326. The patient suddenly appeared retrosternal pain, dyspnea, collapse with increased sweating, and a sharp V neck veins. Which version of PE is in this patient?
- A. *Acute course
 - B. Subacute course
 - C. Recidivism during
 - D. Mixed
 - E. Combined
327. In the patient suspected pulmonary embolism. Which of the following methods investigation is required to clarify the diagnosis?
- A. *Study of blood coagulation
 - B. Complete blood
 - C. Urinalysis
 - D. Determine the level of uric acid
 - E. Confirmation is not required
328. In the patient suspected pulmonary embolism. Which of the following methods investigation is required to clarify the diagnosis?
- A. *ECG
 - B. Complete blood
 - C. Urinalysis
 - D. Determine the level of uric acid
 - E. Confirmation is not required
329. In the patient suspected pulmonary embolism. Which of the following methods investigation is required to clarify the diagnosis?
- A. *Radiography of the chest cavity
 - B. Complete blood
 - C. Urinalysis
 - D. Determine the level of uric acid
 - E. Confirmation is not required
330. In the patient suspected pulmonary embolism. Which of the following methods investigation is required to clarify the diagnosis?

- A. *Angiopulmonography
 - B. Complete blood
 - C. Urinalysis
 - D. Determine the level of uric acid
 - E. Confirmation is not required
331. In the patient suspected pulmonary embolism. Which of the following methods investigation is required to clarify the diagnosis?
- A. *Lung scintigraphy
 - B. Complete blood
 - C. Urinalysis
 - D. Determine the level of uric acid
 - E. Confirmation is not required
332. In the patient suspected pulmonary embolism. Which of the following methods investigation is required to clarify the diagnosis?
- A. *Study of blood coagulation
 - B. Complete blood
 - C. Urinalysis
 - D. Determine the level of uric acid
 - E. Echocardiography
333. In the patient suspected pulmonary embolism. Done radiography of the chest cavity. Which of the following symptoms are indicate pulmonary embolism?
- A. *The rise of the dome diaphragm
 - B. Pulmonary fibrosis root
 - C. Availability Calcinates
 - D. Increased vascular pattern
 - E. No right answer
334. In the patient suspected pulmonary embolism. Done radiography of the chest cavity. Which of the following symptoms are indicate pulmonary embolism?
- A. *Pleural effusion in the sinuses
 - B. Pulmonary fibrosis root
 - C. Availability Calcinates
 - D. Increased vascular pattern
 - E. No right answer
335. In the patient suspected pulmonary embolism. Done radiography of the chest cavity. Which of the following symptoms are indicate pulmonary embolism?
- A. *The wedge-shaped shadow atelectases
 - B. Pulmonary fibrosis root
 - C. Availability Calcinates
 - D. Increased vascular pattern
 - E. No right answer
336. In the patient suspected pulmonary embolism. Done radiography of the chest cavity. Which of the following symptoms are indicate pulmonary embolism?
- A. *Breaking vessels near the root of the lungs
 - B. Pulmonary fibrosis root
 - C. Availability Calcinates
 - D. Increased vascular pattern
 - E. No right answer
337. In the patient suspected pulmonary embolism. Done radiography of the chest cavity. Which of the following symptoms are indicate pulmonary embolism?
- A. *Hyperperfusion of the contralateral lung
 - B. Pulmonary fibrosis root
 - C. Availability Calcinates
 - D. Increased vascular pattern
 - E. No right answer

338. In the patient suspected pulmonary embolism. Done radiography of the chest cavity. Which of the following symptoms are indicate pulmonary embolism?
- *Dilation of the right ventricle
 - Pulmonary fibrosis root
 - Availability Calcinates
 - Increased vascular pattern
 - No right answer
339. In the patient suspected pulmonary embolism. Echocardiography. Which of the following symptoms are indicate pulmonary embolism?
- *Advanced, hypokinetic right ventricle
 - Normal right ventricle
 - Spasm of the proximal pulmonary arteries
 - Relationships right ventricle / left ventricle is not broken
 - No right answer
340. In the patient suspected pulmonary embolism. Echocardiography. Which of the following symptoms are indicate pulmonary embolism?
- *Increased ratio of right ventricle / left ventricle
 - Normal right ventricle
 - Spasm of the proximal pulmonary arteries
 - Relationships right ventricle / left ventricle is not broken
 - No right answer
341. In the patient suspected pulmonary embolism. Echocardiography. Which of the following symptoms are indicate pulmonary embolism?
- *Dilation of proximal pulmonary arteries
 - Normal right ventricle
 - Spasm of the proximal pulmonary arteries
 - Relationships right ventricle / left ventricle is not broken
 - No right answer
342. In the patient suspected pulmonary embolism. Echocardiography. Which of the following symptoms are indicate pulmonary embolism?
- *Increasing the speed of blood tricuspid regurgitation $> 3.7 \text{ m / s}$
 - Normal right ventricle
 - Spasm of the proximal pulmonary arteries
 - Relationships right ventricle / left ventricle is not broken
 - No right answer
343. In the patient suspected pulmonary embolism. Echocardiography. Which of the following symptoms are indicate pulmonary embolism?
- *Violation of blood flow from the right ventricle
 - Normal right ventricle
 - Spasm of the proximal pulmonary arteries
 - Relationships right ventricle / left ventricle is not broken
 - No right answer
344. In the patient suspected pulmonary embolism. Echocardiography. Which of the following symptoms indicate pulmonary embolism?
- *Advanced vena cava inferior, which has persisted for inspiration
 - Normal right ventricle
 - Spasm of the proximal pulmonary arteries
 - Relationships right ventricle / left ventricle is not broken
 - No right answer
345. Patients with suspected pulmonary embolism made angiopulmonography. Which of the following symptoms is direct?
- *Vascular filling defects
 - Asymmetry of vascular contrast material filling
 - Slow progress or stasis of contrast

- D. Increased pulmonary artery trunk and its major branches
- E. No right answer
